Much the same dilemma presents itself to photometrists. Scientifically and legally, candles are no longer in repute and the amyl acetate standard is the new unit of light strength. Shall a ratio between the amyl acetate lamp and the candle be employed and all determinations of the light strength of illuminating sources made against the amyl acetate standard be finally expressed in candle power terms? The first step towards an intelligent decision is the consideration of the ratio between the light strengths of the amyl acetate lamp and the candle.

It has been insisted upon that experimental evidence has shown that the light strength of the candle is a widely varying and uncertain quantity. Abandoned for this reason, it is vain to seek for a definite ratio between the amyl acetate lamp and the candle, or between any constant standard of light and the candle. The numerous candle-power ratings in the literature of photometry are only mean values obtained between wide extremes, or merely figures, and represent no physical quantity. Violle, a French physicist, states the ratio as low as,

$$\frac{\text{English Candle}}{\text{Amyl Acetate Lamp}} = 1.02.$$

The German Physical Institute places it at 1.14, and other investigators as high as 1.22.

The term candle-power being meaningless as a quantitative expression, and the amyl acetate lamp being fairly precise as a standard light, we, in this country, might follow the example of foreign photometrists and express illuminating power in terms of Hefner Units (Hefner Licht, is the current term in Germany). It might be especially desirable that the manufacturers of incandescent lamps should begin the innovation by marking their lamps in Hefner units instead of candle-power. An inconsiderable increase in illuminating power, and probably the majority of lamps would need none, would change the present candle-power ratings to conform to the new scale of:

| | | | |
|---|---|---|---|
| 10 | candle-power..... | 12 | Hefner units. |
| 16 | " ..... | 20 | " |
| 20 | " ..... | 25 | " |
| 25 | " ..... | 30 | " |
| 32 | " ..... | 40 | " |

A reasonable objection to such an innovation in lamp ratings is that the change once made, a better light standard than the amyl acetate lamp might be introduced, and the necessity would arise for a second revision of lamp ratings, and so on without an end. Referring again to the analogy between this subject and the meter as a standard of length, it may be advanced that the meter is a purely arbitrary standard of length, though it was designed to be an absolute one, and for similar reasons the candle-power may be retained as an arbitrary light unit both in name and assigned value. The analogy is only apparent, for there can exist no material representation of the candle-power unit of light, because it is an indeterminate quantity. Candle-power is then a mere name corresponding to no physical quantity, and in the adoption of the Hefner unit along with the material amyl acetate standard there is in reality nothing to relinquish but a mere custom. According to an established scientific custom there is no inconsistency in naming the unit of light after an individual connected with its development. The custom itself, though now seemingly general and firmly established, is perhaps a questionable one. In the old mythology every aspect of nature was personified and named, and though the application has changed, the principle still survives in scientific practice.

The more rational procedure would be that followed in reference to heat. A quantity of heat is expressed in terms of Heat Units or British Thermal Units. This is thoroughly scientific, entirely satisfactory and produces no confusion whatever. There are certain interested parties now at work, however, who are anxious to impose the name of an individual upon the heat unit, but as the change is unnecessary it is to be hoped that engineers and physicists will be conservative and adhere to the prevailing practice and continue the use of the term Heat Unit.

Let us apply the same reflections to the discussion in hand. Abandoning candle-power units and such descriptive and personified terms, let the illuminating power of all sources of illumination be expressed in Light Units simply. This is entirely expressive and can lead to no confusion whatever. The value of the light unit applied to the candle, Methven screen and such indeterminate light sources, can not be expressed because of variations in the light strength. But applied to the amyl acetate lamp it is a quantity whose value can be stated within very narrow limits of uncertainty. As the science of light standards advances and the light strength of the actual standard becomes expressible with very great precision, the term Light Unit will still apply with equal force. If the value of the Light Unit is changed by consent of a congress or other body, it will cause no more confusion than was occasioned by the change in the value of the Heat Unit by a redetermination of the mechanical equivalent of heat.

The unit for expressing the quantity of a phenomenon must be of the same character is the thing measured, and this unit value can be no more precise than the value of the thing measured. As the measurement of the phenomenon grows more and more precise, to the same extent will the value of the unit become more definite.

Adhering still to the descriptive designation of the light unit, it has been proposed to call it the "Photon." This would be a perfectly general descriptive term applying equally to all standards. Should the term Hefner unit prove objectionable, and a descriptive unit, based on the amyl acetate lamp, be desired, following the analogy of ammeter, the name "Amate" could be coined. But applying the criterion just established, both the terms photon and amate are objectionable, it being unnecessary to employ for such purposes an intellectual cipher code.

The Incandescent Platinum Standard.—Violle endeavored to realize an absolute, or simple and reproducible standard of light by employing a definite light giving area of an incandescent metal. He finally selected platinum as best adapted for the purpose. In order that the temperature of incandescence which he used should be reproducible with accuracy, he selected the temperature of solidification of the metal. When a metal has been fused and begins to solidify, its temperature remains constant until the change of state has been accomplished. Though the same thing is true for the act of fusion of a metal, there are reasons of which discussion would prove tedious here, why the temperature at which fusion occurs is not always the same, but varies with the past history of the metal. Platinum, in common with iron, for example, when solidifying, recalesces, or the light emitted suddenly flashes into greater brilliance, for a very short time. Violle, taking advantage of this, selected the moment of recalescence or flashing during solidification for the determination of the light strength. The mass of platinum, about one kilogramme, was melted by a compound blowpipe in a lime crucible. After the fusion of the platinum the crucible was placed immediately under a water-cooled screen, pierced with a circular hole of the area of one square centimeter. During the flashing period the surface of the incandescent platinum was found to emit a light strength nearly 19 times as great as that of the amyl acetate lamp for the square centimeter. This standard was legally adopted, though largely hypothetical, by the Paris Electrical Congress of 1881. Subsequent experiments have not confirmed the utility of this source of light and the attempt to realize a precise standard of light from

Digitized by Google

incandescent platinum has been practically abandoned.

To recapitulate.—The leading standards of illuminating power proposed and actually used are candles, the Methven screen, the pentane and amyl acetate lamps, and the carbon arc and incandescent platinum standards.

## LIGHTNING AND LIGHTNING ARRESTERS.

BY HENRY E. RAYMOND.

The records of discharges with the apparatus described by the writer in the last number of the American Electrician dnring a number of storms have furnished very instructive and valuable data, but I will give only a few in the accompanying table.

RECORD OF LIGHTNING ARRESTER DISCHARGES, JUNE, 1898.

| Number of Times the Arresters Discharged. | | | | Coincident Lightning Discharge. | Remarks. |
|---|---|---|---|---|---|
| A | B | C | D | | |
| .. | .. | 3 | Not connected. | About 1 mile off. | Fairly sharp. |
| .. | .. | 2 | | " " " | " " |
| .. | .. | 3 | | " " " | " " |
| .. | .. | 1 | | " " " | " " |
| .. | 1 | 4 | | " " " | More " |
| .. | 2 | 1 | | " " " | " " |
| .. | .. | .. | | " 2 miles " | Faint " |
| .. | .. | .. | | " " " | " " |
| 1 | 1 | 3 | | " 200 yards " | Very severe and close. |
| .. | 2 | 1 | | " " " | " " |
| .. | .. | .. | | " ½ mile " | Less severe and farther. |
| .. | .. | 1 | | " " " | Fairly sharp. |
| .. | 1 | 1 | | " 500 yards " | Quite " |
| 1 | 1 | 1 | | " " " | Very " |
| .. | .. | .. | | " 1 mile " | Fairly " |
| .. | 1 | .. | | " " " | Less " |
| .. | .. | .. | | " 2 miles " | Faint " |
| .. | .. | 1 | | " 1000 yards " | Fairly sharp. |
| .. | 1 | .. | | " " " | " " |
| .. | 1 | 2 | 10 | 10 in 6 minutes | Lightning at varying distances and severity. |
| 1 | 2 | 8 | 36 | 38 " 30 " | |
| .. | 5 | 3 | 17 | 17 " 20 " | |
| 2 | 4 | 5 | 9 | 9 " 12 " | |

NOTE.—Discharges of more than one for each "flash" consisted of one for each main discharge, followed by smaller ones. The secondary ones were probably due to the recharging of the air drained by the first discharge.

These records show distinctly that to the comparatively low frequency of lightning discharges and probable low voltage or tension induced, a resistance introduces a smaller factor of opposition than an increased gap does, there being certain definite relations.

If now we note the forms of gaps shown in Figs. 7 to 9, we would say that Fig. 9 would discharge static more readily than

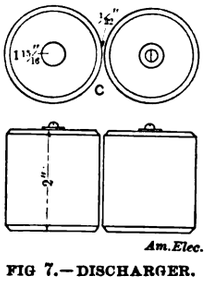

FIG 7.—DISCHARGER.

Fig. 7 would, and that the proportion of readiness would go in order through Figs. 9 to 7. Purely static probably would escape more readliy from Fig. 9 than from Fig. 7, but the disruption discharge from either jars or line shows a preference to Fig. 7. This is presumably due to the capacity of the cylinders. In fact, in testing the tanks before alluded to, I found that the path was best when it contained a gap than when the tanks were directly to ground. The gaps must be between dischargers with considerable mass.

There is one more experiment to complete the present list, and it is shown in Fig. 10. This was to see what relation resistance had to gap when used on "line arresers." It was found that up to certain limits it does not affect the discharge materially, but that when over 5000 ohms, for this size and length, a certain reactance is noticeable. This may be due as much as anything to the segregated condition of conducting particles in the graphite mixture. This figure shows an arrangement with six arrests on a 2500-volt system with two circuits. The wires are all on the same poles, and the arresters are arranged so as to give no favor to any one. The carbon resistances are all alike in size, being 6 ins. x ¾ in. in diameter, and the gaps vary slightly in length. In A the resistance is 5000 ohms, the total gap

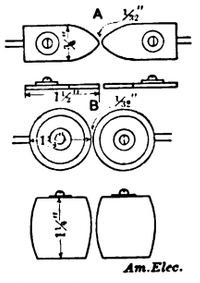

FIG. 8 AND 9.—DISCHARGER.

.052 ins.; in B the resistance is 80 ohms, the total gap .070 ins.; in C the resistance is 1200 ohms, the total gap .059 ins.; in D the resistance is 300 ohms, the total gap .057 ins.; in E the resistance is 600 ohms, the total gap .067 ins.; in F the resistance is 150 ohms, the total gap .067 ins.

An average taken from the records of several storms shows a ratio of discharge about as follows: A, 17 times; B, 9 times; C, 12 times; D, 14 times; E, 10 times, and F, 11 times. It will be noticed that the difference in the number of discharges is more in proportion to the difference in gap distance than in resistance.

Again, a question naturally arises, why should there be this dissimilarity of action between these arresters and the ones under Leyden jar tests? To best answer this, let us go over some of the most vital points.

In the Leyden jar experiments the results tended to show the following: First, that the lower the voltage the smaller the effect resistance has upon the discharge. Second, the greater the capacity, the less the discharge is affected by resistance. Third, that the shorter the resistance for given cross section, the less its influence. Fourth, that this discharge will be affected by any reactance to quite an extent.

In the action of arresters on the line, we note, first, that the discharge is opposed by considerable length of resistance, and but little by amount of resistance in ohms in shorter lengths. Second, that the length of gap determines the striking point of the arrester. Third, that the inductance of the line introduces a favorable factor. Fourth,

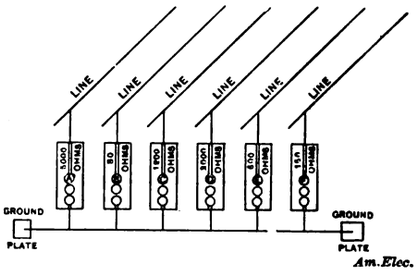

FIG. 10.—ARRESTERS ON 2500-VOLT, THREE PHASE SYSTEM.

that the capacity of the discharges affects the striking point in that for a given distance the greater the capacity, the lower the striking tension. Fifth, that reactance coils offer but little impedance to lightning discharges, and a considerable opposition to the Leyden jar sparks. Sixth, that the voltage of line discharge is much less than that of the Leyden jar, with a long gap in series with its circuit.

Let us now consider the line as a condenser alternately charged by the atmospheric disturbances and discharging to earth at certain conditions of electrostatic unbalancing, or dielectric strain. We have these differences between this condenser and its action, and the Leyden condensers and their action: The line is presumably of higher capacity, and certainly of greater self-induction. The lightning discharges are evidently of much the lowest frequency, as is indicated by the slight effect a reactance coil has upon them. It is easy to see how these few points explain the difference in action, and how they explain the fact that an arrester with a short gap and a moderate resistance in series will take a line discharge in preference to one without resistance, and with a longer gap.

There is one further condition, the presence of which we may guess from the bearing it would have upon the operation of arresters, and which we can reasonably and logically substantiate theoretically. The laboratory tests brought to light the fact that the lower the voltage of discharge with a fixed capacity, the less it would be deflected by a resistance. We have in the line certain fixed conditions and certain variable ones.

The variable ones are the capacity and the inductance, both of which are dependant on the area of country or length of line which is affected by the "storm." The fixed conditions are low frequency of discharge oscillations, and a certain gap to ground. The self-induction is always greater than in the Leyden jar arrangements, and the capacity generally is greater. With certain capacity a given charge will induce a certain potential, the tension being inversely proportional to the capacity. This tension will be further re-

Digitized by Google

duced by the inductance in series, and the fixed gap will prevent a rise in pressure over a certain point.

The resistance is like the spring in a relief valve. An arrester without resistance may be likened to a relief valve which depended upon its own weight-mass to keep it closed, and it is obvious that the former would possess by far the least inertia. A lightning discharge has been likened to a bullet. It seems to have a similar impetus, and similar lack of momentum as of mass. It should be remembered that lightning discharges have to pass back and forth along the retarding influence of inductance, and our bullet, to make the simile fair, should pass through some medium like water, or be retarded by an elastic cord. Under such conditions as these, it is evident that an arrester or target offering the least inertia or its equivalent will be the first to give way. It is needless to add that enough resistance must prevent the passage of any quantity of dynamo current.

I want to reply to some objections which have been made to a very convenient method of rating arresters. It has been stated that it is incorrect to say that an arrester is set or designed to discharge at 2000 volts or 3000 or 5000, as the case may be. If we were going to use arresters for the protection of circuits under the influence of Holtz machines, Leyden jars, etc., it possibly would be incorrect. If our arresters are to divert only natural discharges it is perfectly correct to state that they will break down at a certain potential, because, if we take a number, which jump at various transformer potentials, and place them on the line, we will find a ratio of discharge very closely allied to the ratio of potential breakdown. No one imagines that the machine voltage is going to rise to the amount, and this ratio of breakdown under commercial voltages gives a very convenient way of referring to relative gaps. We test all machinery by the high potential test, not because we think that the voltage is going to rise to such a degree, but because it gives us comparative ratings of dielectric strength. The same idea is readily applicable to lightning arresters.

## LIMITED ELECTRIC STATIONS.

BY ALTON D. ADAMS.

A central station of low first cost and high operative efficiency to serve a limited area is a common problem in electrical design. Hundreds and thousands of small cities and towns have nearly their entire business interests within a radius of one-half mile from a central point, and the possible demand for electric light and power is such as to warrant only a very moderate outlay. When the fact that very many small central stations, in places similar to the above, run at a loss is held in mind, the necessity for careful selection of equipment is evident, and the designing engineer must decide a variety of questions with no little skill to insure a financially successful plant.

The station under consideration would be required to operate from eighteen to twenty-four hours per day, and this fact has an important bearing on the average efficiency of electrical equipment, when it is considered that the maximum load of lamps on a central station usually continues but two or three hours per day, and the load during the remainder of each day is but a small part of the maximum amount, since the variation of losses inside and out of the station does not necessarily rise and fall in the same ratio as the load.

There are two main classes of electric generators, either of which may be used to operate incandescent lamps, namely, those generators intended to connect directly with the lamps, through the proper conductors, and those intended to connect with transformers, but having no electrical connection with the lamps. Generators connected directly with the lamps are limited in electric pressure or volts to the voltage of the lamps, plus the small loss of pressure allowed in the connecting wires. Generators for connection to transformers are of the alternating current type, and may be of any desired voltage, as the proper voltage for lamps is supplied by a suitable transformer.

Alternating current generators with transformers have been much more frequently selected for stations like the above than have the type of generators suitable for direct connection to the lamps, for two reasons: First, because the weight of conductors to supply a given number of lamps at a fixed distance and per cent. of loss varies universely as the square of the volts or electric pressure at which the energy is supplied; and secondly, because until several years ago the highest practical electric pressure at which lamps could regularly be had was about 110 volts. At 110 volts the weight and cost of conductors is very large compared with other parts of the equipment, even on distances so short as one-half mile; while a voltage may readily be selected for alternating current generators, as 1000 or 2000 volts, which will reduce the weight and cost of conductors to a very low figure.

The great saving in conductors made possible by the transformer system at 1000 volts as compared with the 110 volt system is shown by the ratio, $(110)^2 \div (1000)^2 = 0.0121$ in weights of conductors for the 1000-volt system, compared with weights for the 110-volt system.

A third method of distribution, known as the three-wire system, by which the station voltage could be increased to from 220 to 250 volts, with 110-volt lamps, has also been possible, but being patented, its use has been mostly limited to stations buying their electrical machinery of a certain company. Considering at first what are called the outside wires of the three-wire system, the weights of conductors required for it, compared with those for the 1000-volt transformer system are shown by the ration $(1000)^2 \div (250)^2 = 16$., that is sixteen times the weight of conductors is required for the two outside wires of the three-wire system as for the 1000-volt system; but the third or neutral wire of the three-wire system is usually made of the same size as each of the other two, so that the total weight of conductors for the system becomes $16 \times 1.5 = 24$ times the weight necessary for the 1000-volt system.

The 125-volt system, connecting dynamos directly with lamps, has been used in a few small stations, serving very limited areas; the 250-volt three-wire system has been very largely used by stations buying their electrical machinery from a certain company, and its use would have been much more extensive were it not for the patent limitations above named.

Reasons for the continued use of the three-wire system in many cases, and of the 125-volt system in a few stations serving a very small area, are found in the cost of transformers, which must be added to that of conductors for the 1000-volt alternating system, and in the low all day efficiency of the transformer system.

The low all day efficiency of transformers is due to the fact that a large part of the loss in a transformer remains constant, so long as it is connected to the supply of current, no matter how small its load of lamps, or whether it is operating any lamps at all.

Now, as even quite small central stations must operate from eighteen to twenty-four hours per day, and as most of the transformers have only a very light load or no load during most of the time, the constant transformer losses materially reduce the average efficiency. In spite of the cost of transformers and their low average efficiency under working conditions, the transformer system seemed destined to do the great bulk of incandescent lighting from small and medium central stations, had the maximum practical pressure for incandescent lamps remained at about 110 volts, but happily this is not the case.

For several years back incandescent lamps for from 220 to 240 volts pressure have been regularly on the market, and their advent, marking a new era in central station design, necessitates reconsideration of the advantages of direct and transformer systems of incandescent lighting. Allowing a moderate pressure for the loss in conductors, the new high volt lamp permits the same station pressure as the three-wire system—that is, about 250 volts—and therefore requires the same relative amount of conductors, compared with the 1000-volt transformer system, as is necessary for the two out side wires of the three-wire system, which amount, as computed above, is sixteen times that at 1000 volts. It is evident from the above that a fair decision between the merits of a transformer and a direct system for any given case, must rest largely on the relation between the sum of costs for conductors and transformers for an alternating system, and of conductors alone for a system of direct connection from dynamos to lamps, and also on the operative efficiencies of the two systems. The cost of conductors for the 220-volt lamp is to the cost of con-

Digitized by Google

ductors for the 110-volt lamp on the two-wire system as $(110)^2 \div (220)^2 = \frac{1}{4}$; that is, but one-quarter of the weight in conductors is required, and as the three-wire system makes necessary a third wire, equal in weight to each of the other two, the 250-volt two-wire system requires only two-thirds the weight of conductors necessary for the three-wire system, with 110-volt lamps.

To determine, therefore, the best system under the usual circumstances, and free from chances of patent litigation, comparison should be made between the 250-volt, two-wire and the 1000-volt or 2000-volt transformer system.

For purposes of comparison, the cost of electric generators for a given capacity may be taken as the same for either system, though the price of low-pressure generators for the direct work would usually be somewhat lower than those of high pressure for use with transformers. To reach a correct decision as to the merits of heavy conductors alone on one side, and light weight conductors plus transformers on the other, each transmission system should be designed to operate at the same average efficiency during the entire daily run, or at least at some definite efficiency, so that due allowance may be made for difference in efficiencies if any exists. In places of moderate size, the average capacity of transformers which can economically be used is quite small, as individual users usually require but few lamps, and if more than two or three consumers are supplied from the same transformer, the cost of the low pressure wires to lamps becomes too great.

In a plant of moderate size, using transformers, lamps may be assumed to be divided equally between those of forty, sixty and one hundred lamps capacity of sixteen nominal candle power each, and the all day efficiencies of these transformers may be fairly taken at 84, 86 and 88 per cent. respectively.

The average all day efficiencies of above transformers will therefore be $(84 + 86 + 88) \div 3 = 86$ per cent. of the energy delivered to them.

Consider now the cost of conductors on the 220-volt lamp system, and of conductors and transformers on the 1000-volt alternating system to supply one thousand 16-c. p. lamps, taking 55 watts each and grouped at 2500 feet from the station.

The maximum loss in conductors for the direct system at full load may be taken at 14 per cent., or the same as the average all day loss of transformers, although this maximum loss will result in a much lower average loss. With a loss of 14 per cent. in conductors and 220 volts at the lamps, the volts at the dynamos must be $220 \div 86 = 255.8$ and the pressure expended in conductors $255.8 - 220 = 35.8$ volts. One thousand 55 watt lamps consume 55,000 watts, and at 220 volts the amperes must be $55{,}000 \div 220 = 250$.

The area of copper conductors to transmit 250 amperes through 5000 feet of its length with a drop in pressure of 35.8 volts, taking 11 ohms as resistance of a mil-foot of copper is found by the formula for circular mils as follows:

$$\text{C. M.} = \frac{11. \times 250 \times 2500 \times 2}{35.8}$$

Therefore, circular mils = 384070. The weight of a 384070 circular mil conductor, insulated, and 5000 feet long, is about $1308 \times 5 = 6540$ pounds, the weight being about 1308 pounds per thousand feet, and its cost at twenty cents per pound is $6540 \times .20 = 1308.00$ dollars.

Coming now to the alternating system with transformers, the average cost of small transformers may be fairly taken at $1.25 per lamp capacity, so that their total cost for one thousand lamp capacity is $1000 \times 1.25 = 1250.00$ dollars.

As the average efficiency of transformers for all day service is quite low, 86 per cent. in this case, it is desirable to maintain a very high efficiency of conductors in the alternating system, so that the total efficiency of transmission may be as high as practicable. Were there no loss whatever in the conductors between alternating generators and transformers, the efficiency of the system would be lower than that of the direct system on the loss assumed in the direct conductors, since while this loss was taken at its maximum, as equal to the average loss in transformers, its average amount will be much below the maximum and therefore below the average loss in transformers.

It should therefore be noted that while in alternating current transmission with transformers the highest efficiency is at full load, and efficiency drops as load decreases, just the opposite of this is true for the direct system of transmission, in which the lowest efficiency of conductors is at full load, and the efficiency rises as the load decreases.

In consideration of above facts the loss in alternating current conductors for above case may be taken at 2 per cent. for full load, and be less than this at average load.

As one thousand 55-watt lamps consume 55,000 watts, when all lighted, the watts then delivered to transformers, taking their average full load efficiency at 95 per cent., will be $55{,}000 \div 95 = 57893$ watts. To transmit this power over 5000 feet of conductors at a loss in them of 2 per cent. and 1000 effective volts at transformer terminals, requires about 2900 pounds of insulated conductors, which, at 20 cents per pound, cost $2900 \times .20 = 580.00$ dollars. Adding the cost of transformers found above at 1250. dollars and the 580. dollars just found for conductors between generators and transformers, gives a total of 1830.00 dollars, but this does not include any charge for conductors to connect transformers with the lamps on consumers' premises.

With 100-volt lamps a loss of 2 per cent. in wires to transformers, and an average length of 200 feet for these wires, the 55,000 watts consumed by all the lamps require for their transmission about 426 pounds of insulated conductor, which, at 20 cents per pound, amounts to 85.32 dollars, making, with the $1830. above, a total of $1915. for the alternating current transmission system.

The cost of transmission system for the direct current in above case was found to be $1308., so that the alternating system costs 1915. $\div$ 1308 = 1.46 times the direct system of transmission under the fair assumptions above, for a concentrated load at one-half mile from the station. Had the direct system of transmission been designed for the same average efficiency as the alternating, its cost for conductors would have been much less than the $1308 above found, and the increased cost of alternating system over the direct would therefore have been much greater.

Having noted, however, the increased cost of the alternating system for what may be considered ordinary design in each case, it will now be interesting to compare the efficiency of the two systems. The average efficiency of the transformers in above case is 86 per cent., and for the average loss in the two sets of alternating current conductors, with 2 per cent. loss in each at maximum load, about 2 per cent. should be allowed as average loss, making the total transmission efficiency of the system about 83 per cent. on the average.

The loss in conductors of the direct system varies directly as the load on them, and will therefore be 14 per cent. at full load, 7 per cent. at half load, 3.5 per cent. at one-quarter load, and 1.75 per cent. at one-eighth load, of the energy transmitted at each stage of load. It is a fair assumption that full load will last during two-tenths, half load during two-tenths, quarter load during two-tenths and eighth load during five-tenths of the time, in which case the total transmitted energy conveyed at each stage of load may be taken as follows: At full load, $1 \times .2 = .2$; at half load $.5 \times .2 = .1$; at one-quarter load, $.25 \times .2 = .05$; at eighth load, $.125 \times .4 = .05$; the sum of which is $.2 \times .1 + .05 + .05 = .4$.

The part of total energy transmitted at each stage of load will therefore be, for full load $.2 \div .4 = .5$; for half load, $.1 \div .4 = .25$; for quarter load, $.05 \div .4 = .125$; and for eighth load, $.05 \div .4 = .125$.

Applying per cents of loss for the several stages of load, the per cents of total energy lost at each stage of load are: Full load, $.5 \times .14 = .07$; half load, $.25 \times .07 = .0175$; quarter load, $.125 \times .035 = .0043$; and eighth load, $.125 \times .175 = .00218$. The sum of these fractions of total energy is .094 or 9.4 per cent., so that the average transmission efficiency of the direct system is 90.6 per cent. For above case, then, the cost of transmission devices is not only 1.46 times as great with the alternating as with the direct system, but the average transmission loss with the alternating system is 17. $\div$ 9.4 = 1.8 times that with the direct.

The facts illustrated by the above figures seem ample to warrant the growing preference for direct electric distribution over moderate areas.

# CENTRAL STATION OF THE BOSTON ELECTRIC LIGHT COMPANY.

## AN UP-TO-DATE SOLUTION OF THE PROBLEM OF ALTERNATING CURRENT AND SERIES ARC GENERATION AND DISTRIBUTION ON A LARGE SCALE.

In this country the design and construction of alternating current plants as a general rule suffer in comparison with those of direct current plants on the score of permanency, low depreciation and low operating costs. There are several reasons to account for this notable inferiority of the average alternating current installation, among them the older, more developed and more thoroughly standardized condition of direct current machinery and the consequent developments to be expected in alternating current machinery, which make the purchase of expensive alternating apparatus inadvisable. In addition to this is the comparative difficulty of direct coupling alternators to engines, owing to their more rigid requirements of a high peripheral speed, and similar engineering impediments. Alternating current plants have suffered from these conditions, especially where they have been brought into direct competition with the Edison system with its lower depreciation and operating expenses.

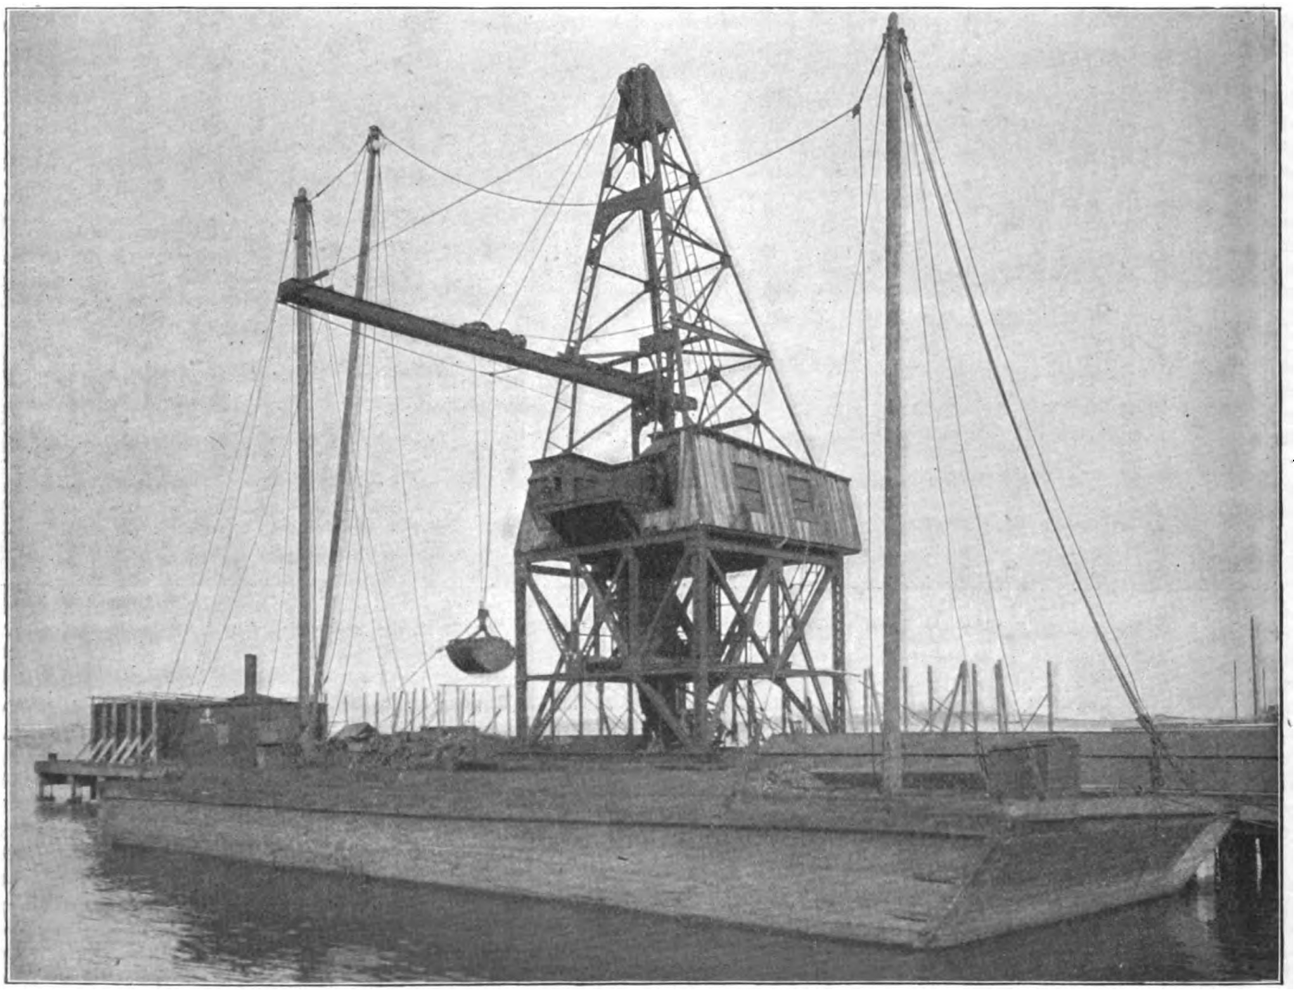
A plant in the design of which the factor of long life and economical operation for several decades to come has been studied with more care than it has in any other alternating current central station in this country, is that of the Boston Electric Light Company. Previous to this year the company operated four generating stations with the usual conglomeration of varied types, sizes and speeds of engines, belted to series arc machines and 500 volt dynamos. The new generating station, which will eventually take the whole load of the four old stations, is built in South Boston, on a plot of ground with a water frontage formerly occupied by the historic Harrison Loring shipyard.

A GENERAL VIEW OF THE OPERATING ROOM, LOOKING FROM GALLERY OVER OFFICES.

### THE BUILDING.

The structure is of the now generally approved type for central stations, consisting of two main bays, separated by a fire wall, and each covered with a nearly flat roof of hollow tile on steel trusses supported on steel columns carried up in the brick walls. The building is laid out for a row of six batteries of two boilers each on one side of the fire wall, and six engines on the other side, four of which have already been erected. The boiler room roof spans also an immense coal pocket, separated from the fire room by a wall, which can be eventually removed if necessary, as it does not support the roof spans, in which case another row of boilers could be put in facing the same fire room. The engine room is also wide

Digitized by Google



enough for two rows of generators, the space of the second being filled now by motor-driven arc dynamo sets, which it is expected will eventually be displaced by improvements, which will enable arc lights to be carried direct by large engine-type generators without the use of a lot of small series machines.

The rated generating capacity of the four machines now erected is 6,000 kilowatts, which could be increased to 9,000 by the addition of two other machines to the present row, and this could again be doubled to 18,000 kw. in the building now erected by the addition of the other row mentioned; still further increase is provided for by space sufficient to double the length of the building, giving with machines of the type now in use a rated output of 36,000 kilowatts with a 50 per cent. overload capacity. In all probability, however, by the time the load becomes of this magnitude, larger sets giving a greater output per square foot of floor space would be used, giving a still larger figure as the capacity of the area provided for the station. It will thus be seen that the company has allowed a generous provision for future extensions.

The building is of brick, with a plain exterior, on rough stone masonry foundations, carried down to a solid sub-stratum at a depth of about nine feet. Its most striking characteristic is the mammoth brick stack which is 225 ft. in height, with an 11-ft. bore and an octagonal base, 22 ft. between faces at the floor level. Its foundations consists of a grill work of I beams laid in concrete 19 ft. deep. The chimney is capped with cast-iron segments, weighing in all about seven tons. The joints between segments are covered with sheet lead. The space between the

Digitized by Google

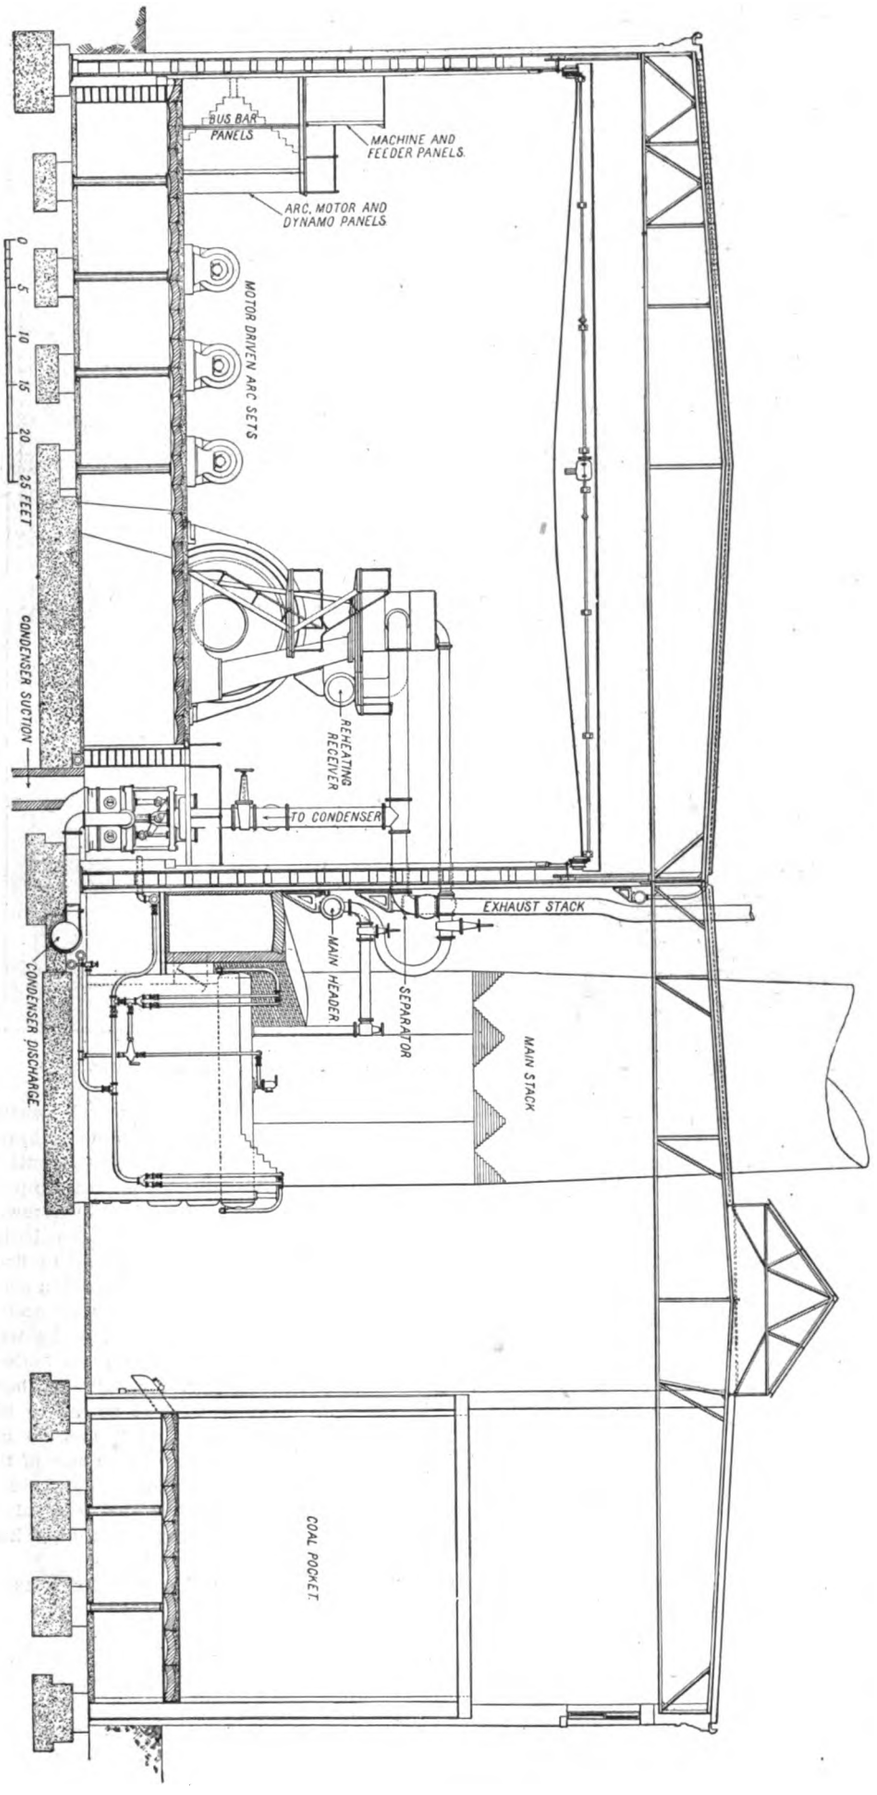
fire brick lining and the shell is utilized as a ventilating flue for the engine room.

The interior of the engine room presents a most striking appearance, owing to the use of white enameled brick for the walls from the floor to the craneways, besides which the underside of the hollow tile roof is plastered with white cement. The windows, of which there is a plentiful supply as the illustrations show, are filled with a form of flock glass which gives no direct sunlight, but gives an admirably diffused illumination. The engine room floor is of terrazzo mosaic. All the machines are painted a dark maroon. The room is lighted by 32 enclosed arcs hung high on the walls, all the wiring to the lights, craneways, etc., being rubber covered and run through hollow bricks embedded in the walls in the proper locations to form the interior conduits. In addition to arcs there are incandescent lamps mounted direct on the engines and on top of the switchboard, in addition to pilot lamps. All wiring from machines to switchboard is in fiber tubing laid in the concrete of the floor, that from main generators being in duplicate in main and basement floors both being in parallel.

All doors are made of wood, covered with about 20-gauge sheet steel, paneled and copper plated, making them fire-proof and less easily dented than tin. The engine room is spanned by a 25-ton crane with two hoists electrically driven.

THE CONVEYOR OVER THE COAL POCKET; DRIVING GEAR AT FURTHER END.



THE BOILER ROOM, SHOWING ARRANGEMENT OF INJECTORS AND FEED PIPING.

### THE COAL CONVEYING APPARATUS.

Running out 150 ft. into the harbor is a pier, carrying a movable tower or crane, from the boom of which coal tubs can be lowered into the holds of the barges or schooners by which coal is transported to New England. The tower was built by the King Bridge Company, and the rest of the coal conveying apparatus by the C. W. Hunt Company. The boom of the unloading tower is swiveled in a universal joint so that its outer end can be swung by hand in a horizontal plane through a small arc to bring it immediately over the hatch into which the tub is to be lowered. The boom can also be run back through the tower to clear the masts

Digitized by Google

A SECTIONAL ELEVATION THROUGH BOILER AND ENGINE ROOMS.

of vessels when the tower is run along the pier. It has a capacity of 100 buckets per hour.

Hanging from the trolley on the boom is a one-ton tub of the Rawson patent, the center of which is supported by one tackle and the sides by another. These tackles are hoisted by independent drums and by moving one faster than the other the bucket is opened or closed. The bucket dumps the coal into a hopper over a sloping grate, which sifts out the smaller stuff but sends all lumps over 10 ins. in size to the crusher, from which the coal descends to the filler of the Hunt conveyor. The hoisting gear is driven by a 500-volt motor controlled on the Ward Leonard system, the generator being in the power house with its field rheostat in the tower. The tower itself, when it is moved along the track, is driven by this same motor. A separate motor runs the crushing equipment.

There is no weighing apparatus connected with the tower, the coal being weighed only after it leaves the storage pocket to go to the boiler room. The tower is handled by two men, and is supplied with current from flexible cables fitted with plugs which may be inserted in any of a number of receptacles distributed along the pier.

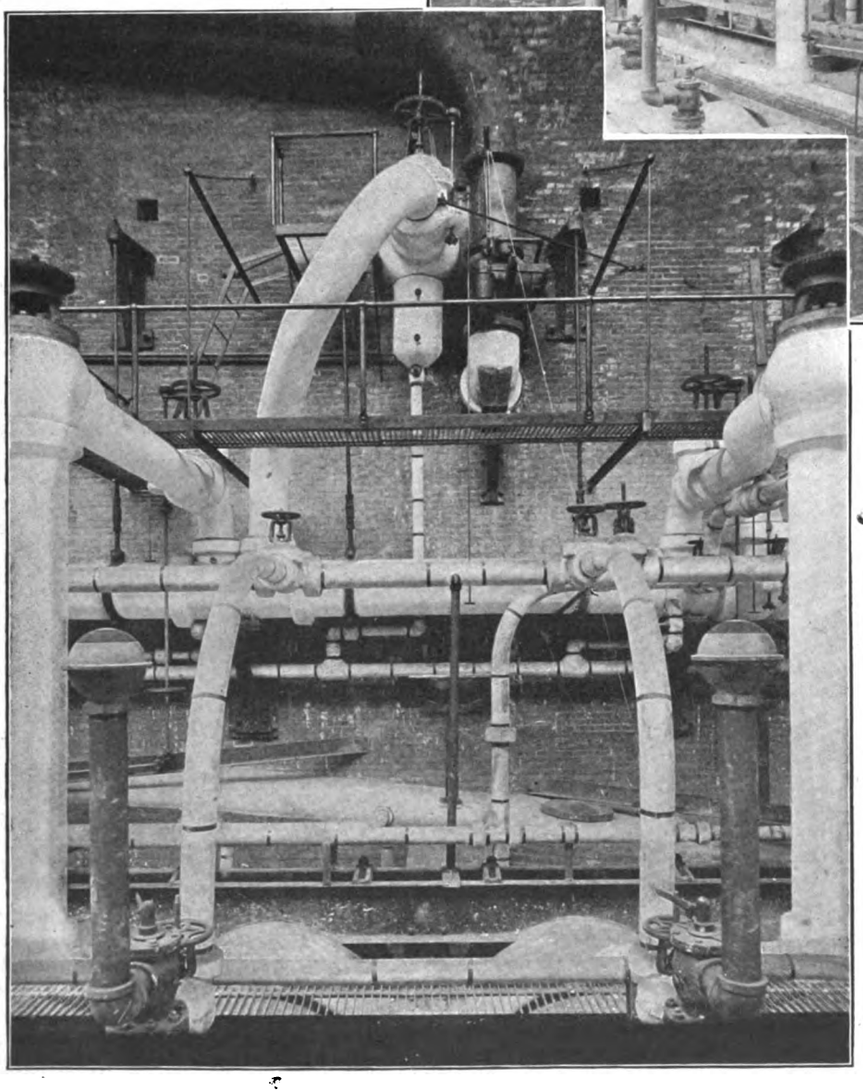
Running along the pier and up an incline over the coal pocket is the conveyor, which is unusually long, having altogether 742 buckets. The conveyor is driven by a 15 h.p. G. E. induction motor, fitted with rotating resistances and short circuiting devices in its secondary to give it a high starting torque.

### THE COAL POCKET.

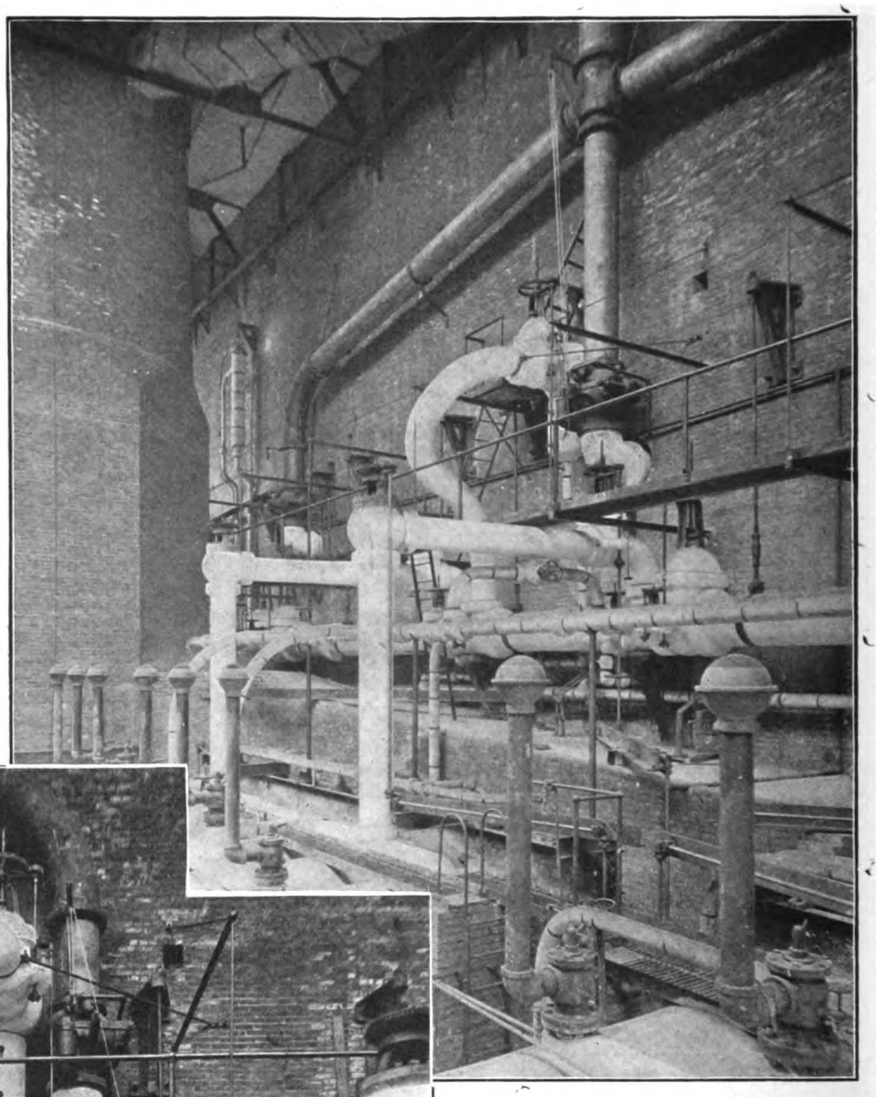
The coal pocket runs the whole length of the building, which is 240 ft., and is 30 ft. wide in the clear, giving room for 9,000 tons of coal. The floor is above the boiler room level, so that small cars can be run under hoppers in the floor to carry the coal to the boiler fronts. The walls of the pocket consist of arches sprung between the columns, their convex sides turned inward to resist the outward bursting pressure of the coal. Alternate columns are fitted with cast-iron pipes with bell and spigot ends opening downward, giving ventilating flues by which any gases generated in the coal can escape.

### THE BOILERS.

The water tube boilers are of the Babcock and Wilcox type, triple drum, and with a nominal output of 550 h.p. each on the centennial rating, grouped two in a battery, thus giving each battery a rated evaporating capacity of 33,000 lbs. per hour, sufficient for one of the engines, which are rated at 2350 h.p. each, with a guaranteed consumption of 12½ lbs. of water per h.p. hour. The boilers are fitted with Hawley down-draught furnaces, and run at 160 lbs. pressure. They deliver their gases to the stack through a brick walled flue 6 x 11 ft. in section, and supported on I beams fixed in the boiler room wall and the boiler setting, with a brick arch floor sprung between



Digitized by Google

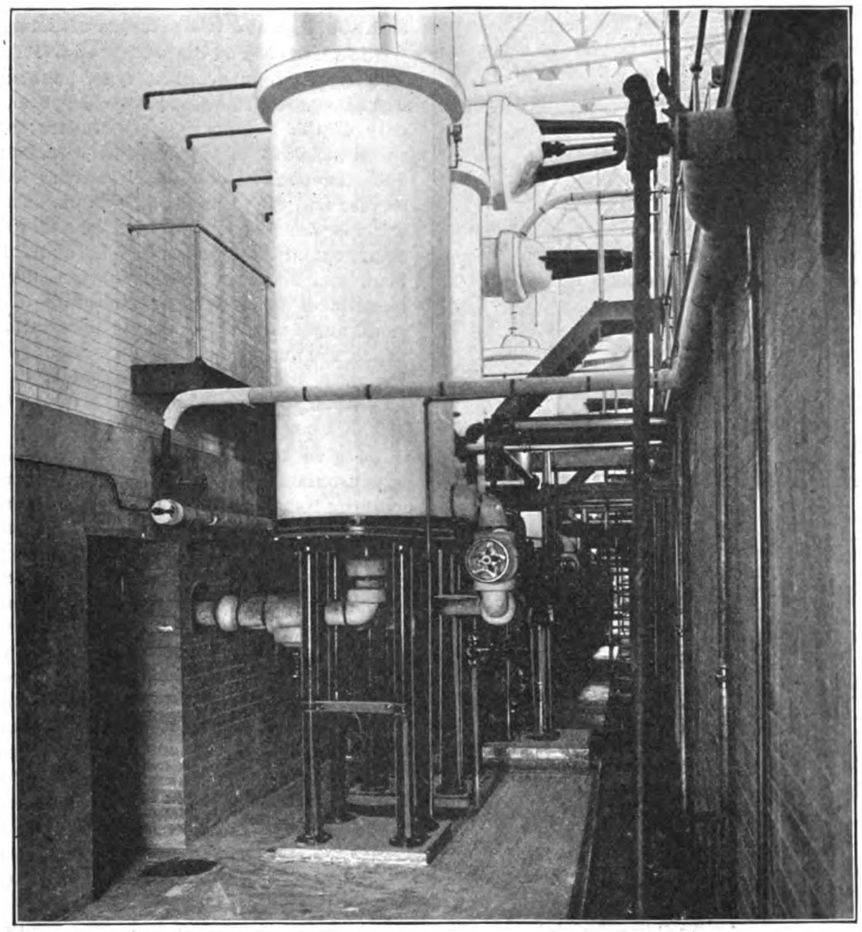


the beams. The flue is lined with fire brick. No economizer is used. The boiler drums are covered with a course of brick and Portland cement, over 2 ins. of magnesia covering. An econometer is installed arranged for connection to any boiler. The cocks of the water level gage glasses are fitted with sprocket wheels carrying chains, which extend down to the floor level, giving a ready means of closing them in case the glass is broken.

THE PIPING.

The steam rises from the boilers through 10-in. nozzles, and passes through Pearson automatic valves which act to check the steam from flowing back into the boilers in case of broken tubes or similar accidents. From these it passes through gate valves and drops into a 20-in. header on the boiler room side of the division wall. This header is hung from brackets and also supported under the tees upon brackets with both transverse and longitudinal slides.

The piping from the boilers comes into special tees in each of which are two nozzles, one of which delivers steam to a



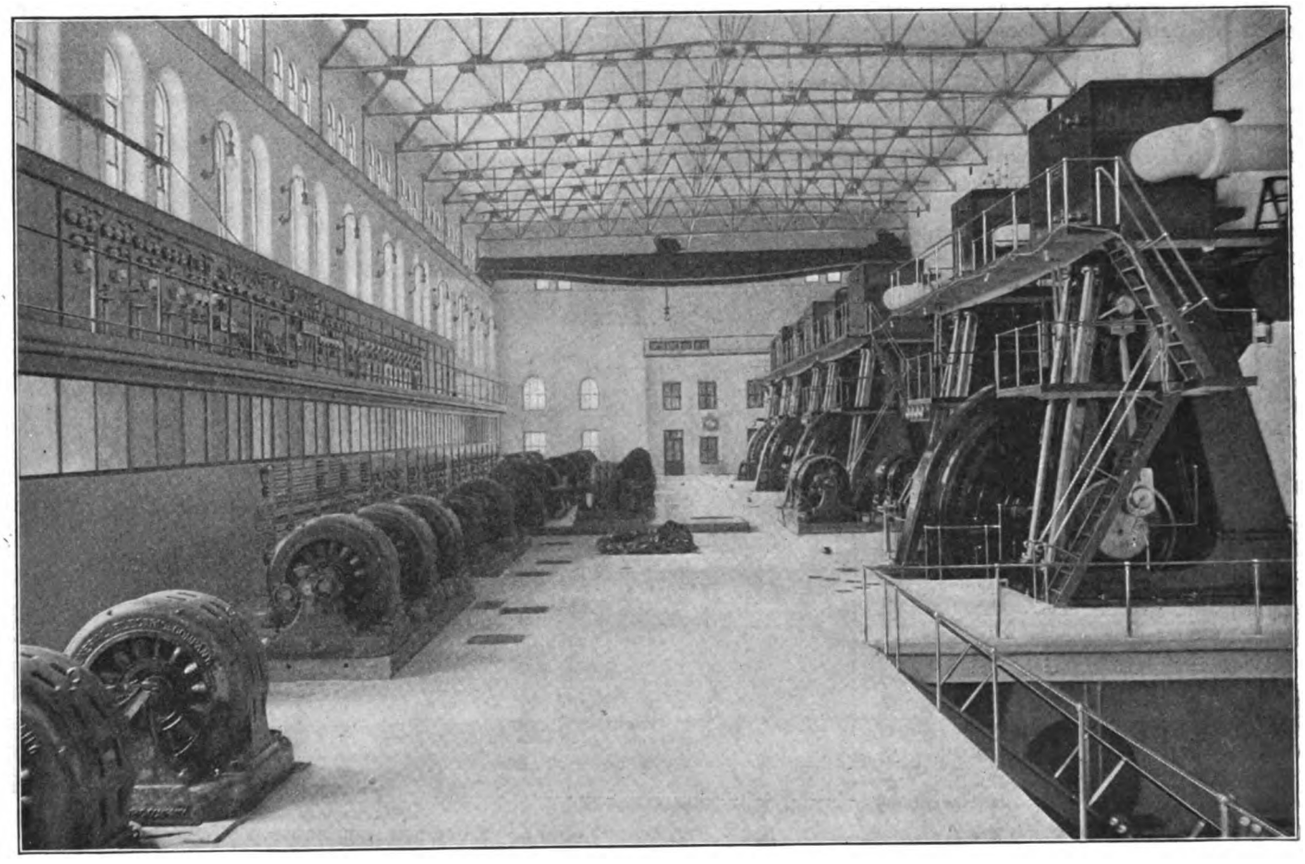
THE PIPING OVER THE BOILERS.

copper bend or loop rising and passing through a gate valve into a Cochrane separator and thence through the wall to the engine stop valve. The steam piping is all of lap-welded steel with screwed flanges. All the valves in the boiler branches are geared down to the floor level, and those in the engine branches and in the header itself are connected with gearing running through the wall into the engine room at a convenient height. Besides this, a gallery has been built to give convenient access to the valves themselves. The header is anchored at the center, and each side of the anchorage has a gate valve, the purpose of the two being to allow the removal of either one by shutting down only half the plant.

The engines discharge their exhaust steam through 24-in. pipes, which run back into the boiler room and there combine in groups of three to an atmospheric riser. On the engine room side of the wall each exhaust branches downwardly through a 24-in. motor driven gate valve to a jet condenser via a surface heater fitted with a by-pass.

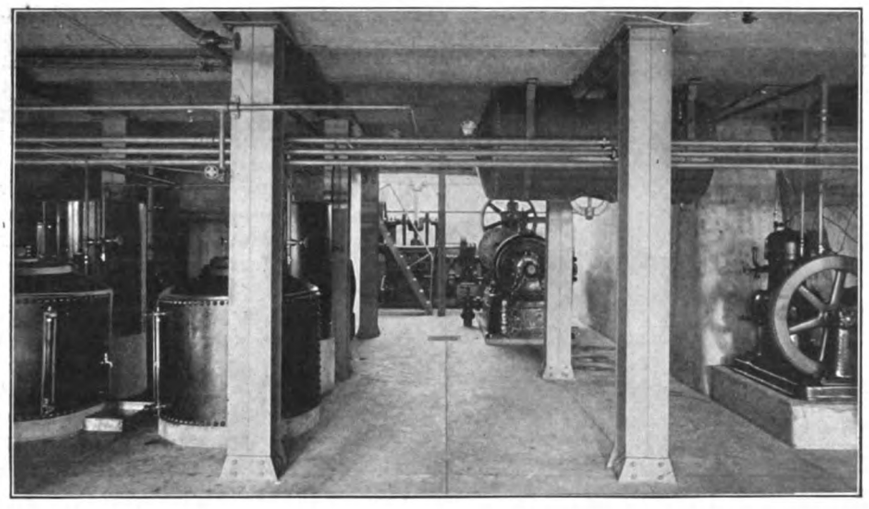
The condensers draw their cold water

Digitized by Google



THE FEED WATER HEATERS.

from a sluiceway 7 ft. in height and 3 ft. in width, running in from the harbor front and discharge into Blake vertical twin air pumps, controlled for constant speed by Mason regulators and delivering their hot water to a 36-in. discharge main buried in concrete, running out again to the harbor. City water is used for boiler feeding, and is handled by the elaborate system described below, equipped entirely with drawn brass piping and cast brass fittings.



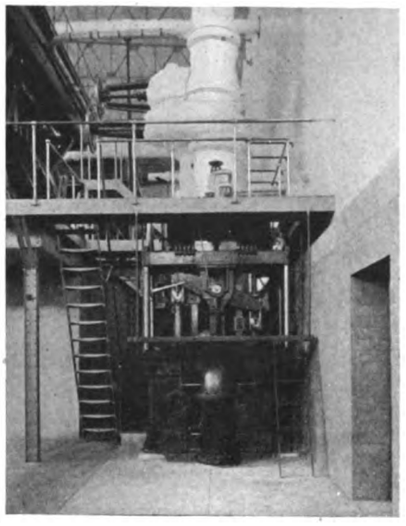
Three Gould's triplex pumps with a capacity of 200 gallons per minute each are driven through triple reduction gearing by 30 h.p. induction motors, and draw water from a supply main and force it into a 6-in. feed main, from which it may pass through the feed water heaters or direct to the boilers.

The pumps are kept running at constant speed, and the feed is controlled by hand operated by-passes. The water passes first through the main heaters described above, and then in series through auxiliary heaters, one for each engine (taking the exhaust of the air pumps and other auxiliaries), and thence through branches to either the front or rear of the drum of any boiler. A reserve source of feeding is obtained by means of an injector at the side of each boiler so piped that it may feed that or any other boiler direct from the city mains.

The usual piping for the purpose of wetting ashes and washing the boiler may be fed through a pump by which its pressure can be raised to work hydraulic flue cleaners, besides which it is fitted

Digitized by Google

THE OILING SYSTEM; OIL TANKS TO THE LEFT, AIR RESERVOIR OVERHEAD AND AIR COMPRESSOR TO THE RIGHT.



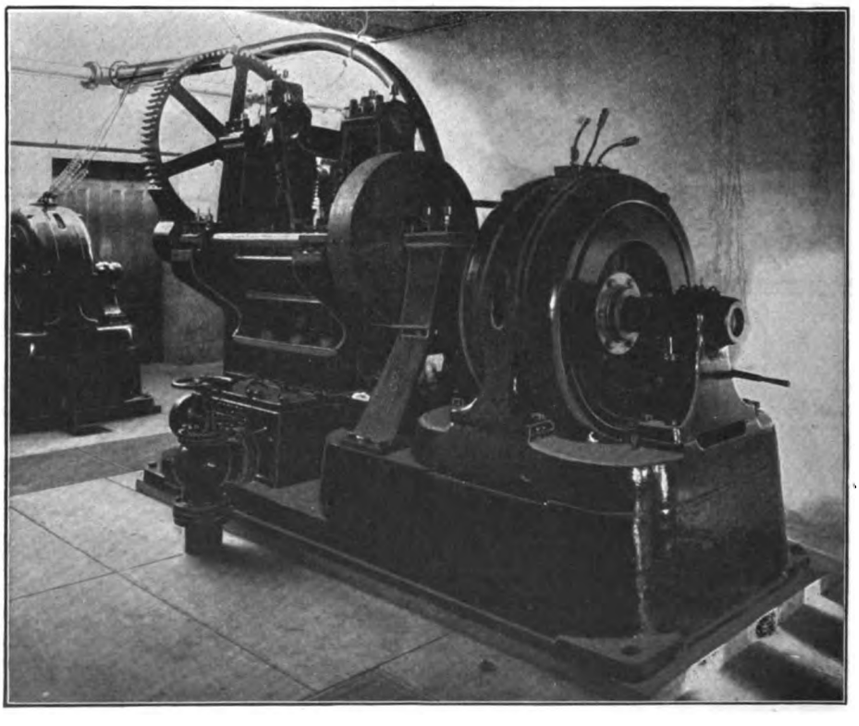
with a standard gage by means of which the boiler gages can be calibrated. All steam piping is drained by means of the Holly gravity return, and is, including the flanges, protected with magnesia covering.

The lubrication or oiling system comprises three 400-gallon pressure tanks in the basement below the dynamo room, two for engine and one for cylinder oil. An air pressure of about 20 lbs. per square inch is kept upon these tanks by a motor driven air compressor, which is also piped to hose connections for blowing the dust off the machines, switchboards, etc. The two engine oil tanks are provided to keep one in service while the other is being filled. The air pressure forces oil from them to one tank on the cylinder platform, which feeds the cross-head slides, etc., and another tank on each main bearing. The drips are carried to Cross oil filters fitted with steam heating pipes. New oil is introduced into the system by the simple process of tapping the barrel into the tanks, and applying the compressed air pressure to it, forcing the oil up and into the tank.

The main journals of the engine are water jacketed, and the water passing through them is returned to the pressure main by a small pump controlled by a float valve.

### THE ENGINES.

The engines are vertical cross compounds with a rating as noted above of 2350 h.p., this being based upon a 23 per cent. cut-off, over and above which there is a large overload margin as the maximum obtainable cut off is some 75 per cent. of the stroke. The engines run at 120 r.p.m., the speed necessary for the 60 cycle alternators to which they are coupled, and have a piston speed of almost 1,000 ft. per minute. They are of the open front marine type, the cranks and the connecting rods being housed in with sheet iron casings to prevent the throwing of oil. Each is provided with a 50-ton, 16-ft. fly wheel and shaft governor within its hub, controlling the cut-off valve in both the high and low pressure cylinders.



ONE OF THE AIR PUMPS.

The valves are of the well-known McIntosh & Seymour gridiron type, running across the cylinder heads. The heads only of the high pressure cylinders are steam jacketed. Steam from these jackets goes through coils in the reheating receivers and then into Holly system. The engines are guaranteed to give a 2 per cent. regulation between no load and full load, and also, on account of the large number of poles of the generators and small angle required to throw them out of phase, are guaranteed to give a maximum variation from the main position of uniformity of rotation throughout a stroke of 1-10 of 1 degree.

To give the proper speed control in synchronizing, *i. e.*, to bring an engine running light down to the speed of others running loaded, in order to throw the generators in parallel, the governors are fitted with speed controlling devices which can be set by hand to adjust the speed through a range of several per cent. This device consists essentially of a leaf of the governor spring, the bending moment of which can be changed by means of a rather elaborate slipping collar, friction wheel and screw device; with this arrangement a distribution of the load between the engines can be changed at will while they are running.

Mr. F. A. Gilbert is President of the Boston Electric Light Company, and to him and Mr. Sidney Hosmer, Assistant General Manager, is due the credit for the main features of the design of the splendid new station. Mr. H. W. Ball designed the structural details of the building, and Mr. Herbert Houghton served as resident engineer. Mr. James T. Boyd designed the details of the mechanical equipment.

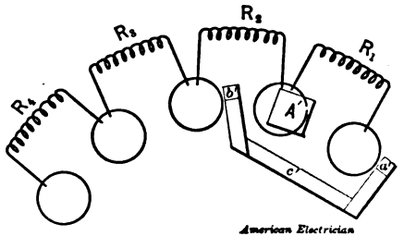
# Among our Foreign Contemporaries

**440 Volt Lighting Station in England.**—A small central station has just been started in the Borough of Bootle, in England, of which very full descriptions are given in the English journals; it is of interest as a sample of a modern plant in that country, and more especially so because it is constructed for 220 volt lamps, which seem to be growing in favor in that country quite rapidly. The population of the place is 54,000 and the total capital expenditure of the station is $185,000, the total connection of lamps at the present time is equivalent to 7500 lamps of 8 c. p. The station is located near a canal, which insures a cheap supply of coal and water. All the buildings are on one floor, which has a base of two feet of concrete; the chimney is 150 ft. high. The three wire continuous current system is used, with 220 volts on each side; there are also balancing transformers and boosters for charging the batteries. The boilers work at 160 pounds pressure and an economizer operated by an electric motor is used. The engines and dynamos are direct connected, there being two of 75 kw. and one of 150, the small ones running at 450 revolutions and the larger at 380; the dynamos are shunt wound and will give any voltage between 440 and 500. Condensers are used in connection with the engine. The balancing transformers and boosters are coupled together in one line, the former being capable of balancing the whole system to within four volts when a current of 100 amperes flows through the middle wire. The boosters are arranged to give any voltage from 10 to 75 with a current up to 130 amperes. An illustration of the connections of the switchboard is shown in the adjoining cut, which is reproduced from the London "Electrician," from which this description is also taken. It is arranged for four dynamos, four feeders, one balancing transformer and two boosters, and also for the middle wire connections from two of the four feeder points. The middle wire is permanently earthed through a recording ammeter. The three panels are of slate and are carried in steel frames cased in on the outside with varnished teak. As is seen, the left hand panel contains the positive connections, the right hand the negative connections, and the middle panel the connections for the middle wire, balancing transformers and boosters. In the circuit of each dynamo there is one minimum current circuit breaker arranged to drop when the current falls below 10 amperes, and interlocked with this is a shunt switch, by which the field is closed through a non-inductive resistance when the circuit is open. The regulating switch for the shunt coils of the dynamo is 25-way. One ammeter is connected in each dynamo circuit and two ammeters in each feeder circuit. At the back of each outer panel there are three horizontal bus-bars, the two upper ones being provided with screw-holes placed opposite the plug holes in the vertical feeder and dynamo bars, and the lower one being provided with screw-holes placed opposite the holes in the dynamo bars only, so that any dynamo may be connected to the traction board. In the center panel there is one double pole starting switch and fuse in the circuit of the balancing transformer, interlocked with the starting rheostat, two rheostats for the transformer fields, an ammeter in the circuit of each balancing transformer, a middle wire ammeter, and the recording ammeter already mentioned. In each battery circuit there is a single way charge and discharge switch, a battery ammeter, a registering meter reading directly in ampere-hours, one battery emergency switch, and one single pole throw-over switch for connecting the battery either to the booster or to the mains. There is also a regulating rheostat for the booster fields. An ammeter registering ampere-hours is fixed in the circuit of each dynamo, and there

THE SWITCHBOARD CONNECTIONS OF AN ENGLISH 440-VOLT STATION.

Digitized by Google

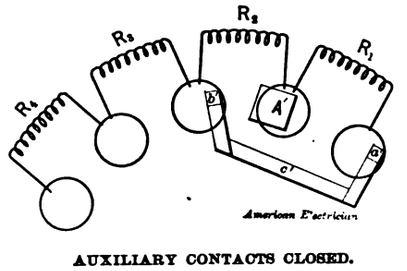
are two recording voltmeters for registering the pressures at the feeding points. There are 125 chloride cells on each side of the middle wire and they can maintain a discharge of 100 amperes continuously for five hours, or 300 for one hour, with a final voltage of 1.86; the cells are in glass boxes resting on wooden trays and supported on glass insulators. The network of wires is fed at four feeding points; the cables are insulated with paper, are lead covered and are run through earthenware troughs, all laid in bitumen. The public lighting includes 92 arc lamps of 10 amperes each, each lamp post having also two incandescent lamps of 16 c. p., which are switched on at midnight when the arcs are turned off. The arcs are connected four in series on the 220 volt mains. The Wright system has been adopted at the rate of 14 cents for the first hour of maximum demand and then 6 cents thereafter.



---

**Brush Resistance in Measuring the Efficiency of Dynamos.**—In using the well known Swinburne method for measuring the efficiency of a dynamo, which consists essentially in running it as a motor unloaded and measuring the current required, it is necessary also to know the resistance of the armature, and in measuring this with a current and drop in voltage, the question arises what the resistance is of the brush contact and whether it is the same when the armature is at rest or in motion. With copper brushes this difference is insignificant, but with carbon brushes it was thought that there may be an error too large to be neglected. To determine this, Mr. Pierron constructed an artificial commutator so arranged that the current passed through 14 brush contacts in series, the object being to multiply the effect and get a fair average. He found that the resistance was lowest when at rest, then increased rapidly as motion began, and then gradually fell, but always remained higher than that measured at rest. The greatest difference was found to be 13.5% when cold and 18% when warm. This, of course, refers only to the brush contact, and as this is in itself small, the total error produced by neglecting this difference would be so small in the ultimate efficiency of the dynamo that it may be neglected, and it is therefore safe to measure the brush resistance when the armature is at rest, even with carbon brushes.

---



**Total Length of Telegraph and Telephone Wires in the World.**—From a recent table of statistics, published in the foreign journals and taken from official sources, it appears that there were at the end of 1898 2,029,893 miles of telegraph and telephone lines in use in the world, of which 167,800 miles were submarine cables and 382,417 were for telephones. The corresponding figures for the mileage of the wires as distinguished from the lines are as follows: 8,285,400, 169,600 and 3,202.950.

**Improvement in Step by Step Resistances.**—In the usual form of adjustable resistances in which a lever arm moves over a succession of contacts between which resistances are connected, it is often desirable to have smaller variations of resistances than those between the steps; to do this in the original construction of the instrument involves making it larger and more expensive. A very simple way of doubling the number of steps even after the apparatus has been made

AUXILIARY CONTACTS OPEN.

and without increasing the number of contact blocks is described in "L'Electricien." As will be seen in the adjoining figures, it consists in adding a U-shaped piece of metal to the handle or crank, but insulated from it, and placing it in such a position that it may be brought into contact with the two neighboring contact blocks, as shown in the second figure, or it may be placed as shown in the first figuse in which it makes no contacts, A rep-

AUXILIARY CONTACTS CLOSED.

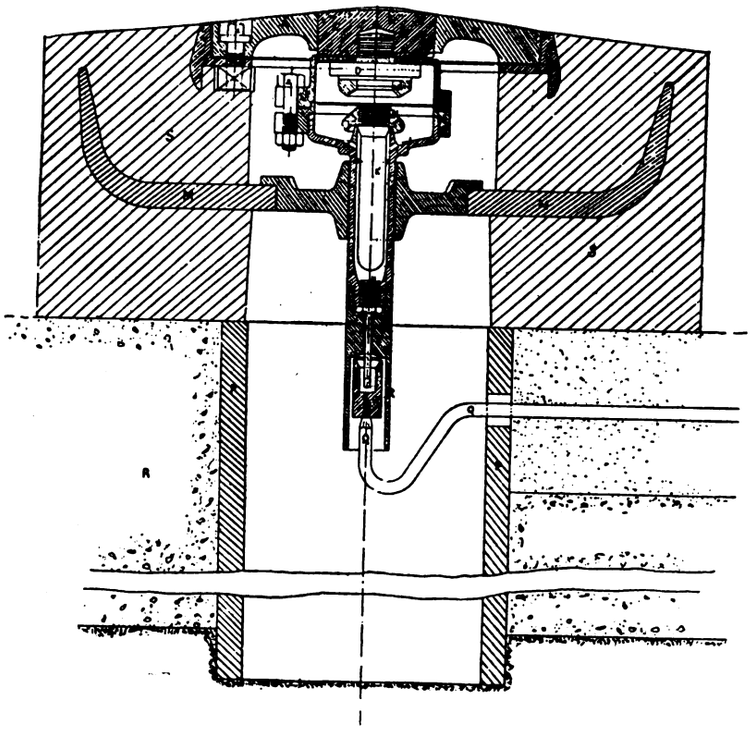
resenting the main contact of the lever arm. In the position shown in the second figure it will be noticed that the two resistances on both sides of the main contact, A, are connected in multiple with each other, thus diminishing the resistance. This arrangement enables one to nearly double the number of steps, as it gives an additional value between each two blocks. Where small variations in resistance are desired, as for instance in regulating the lights for a stage, or in adjusting the resistance of feeders in multiple, etc., this arrangement seems to be a very convenient and simple one.

---

**Reducing Transformer Losses.**—As is well known there is always a continuous loss in the primary of a transformer, whether there is a current in the secondary or not; this loss, although small, is continuous, and amounts to considerable in the year. Numerous devices have been suggested for diminishing it, such as cutting out the transformer when not in use, but few, if any, are used in practice. One method of some interest is to divide the primary and secondary each into two equal parts and couple them in multiple for full load and in series for small loads. The transformer ratio will, of course, remain the same in both cases, but the induction will be reduced to a half for a series connection, the loss due to hysteresis will be reduced more than a half and that due to the heating of the current is increased only slightly, so that altogether there will be an appreciable gain in economy. A somewhat similar system, but applicable only to three phase circuits, was recently described by Kahlenberg in "L'Industrie Electrique." It consisted simply in connecting the three coils first with the end of one to the beginning of the next, forming what is called the triangle or delta system of connection, and then change them to what is known as the star of Y system of connection. In the first case the voltage will be 70% greater than in the second, and the triangular coupling is therefore used for large loads, while the star couple is used for small ones. The change must, of course, be made simultaneously in both the primary and the secondary circuits, so as to retain the same transformer ratio.

---

**Simple Method of Testing Dynamos.**—The dynamo being less liable to get out of order than the engine and boilers, it is customary in a central station to test only the two latter periodically. While this may suffice in most cases, it is advisable, also, to test the dynamo periodically, as in that way any faults developing in it may be noticed before any harm is done. A very simple and quick method of doing this so as to find any changes in the efficiencies of the dynamos is described by Mr. Liebenow in the "Elektrotechnische Zeitschrift." It consists simply in uncoupling the dynamo from the engine or turbine and running it as a motor from the bus bars or from another machine until its speed has reached a certain fixed value; the current is then broken and a stopwatch is started the same moment; the machine will then gradually come to rest and the time which this takes is noted on the stopwatch. If this is done when the machine is new, then at any future time the condition of the machine with respect to the internal losses may be found by making a similar test. The test may be made with the field excited or with the field open and with the brushes on or off, thus giving an opportunity to test the effect of each. If the bearings are not in good order these tests will show it, or if the brush friction has become too great it will be noticed in that test. With the field excited, the armature will come to rest sooner, as the Foucault current losses will then be added to the friction losses in bringing the machine to rest. If not convenient to measure the time with a watch, the number of revolutions made after the current is



Digitized by Google

cut off may be counted by means of a revolution counter, for which purpose an ordinary bicycle cyclometer or similar instrument could be used, care being taken to start the counter at exactly the moment that the current is shut off. In the case of a small dynamo from which the belt can be readily thrown off, it may be brought up to speed by means of the belt instead of using current from an external source. By repeating the test with and without excitation and with and without the brushes a fair idea can be obtained of the Foucault current and hysteresis losses, that due to the friction of the brushes and that due to the bearing and air friction.

Some years ago a similar method was described for measuring the actual instead of the relative efficiency of a dynamo, but it is necessary in that case to know the moment of inertia of the armature, and as this is a troublesome quantity to deal with, the test was repeated with and without a heavy flywheel, and from these two tests the efficiency can then be calculated.

---

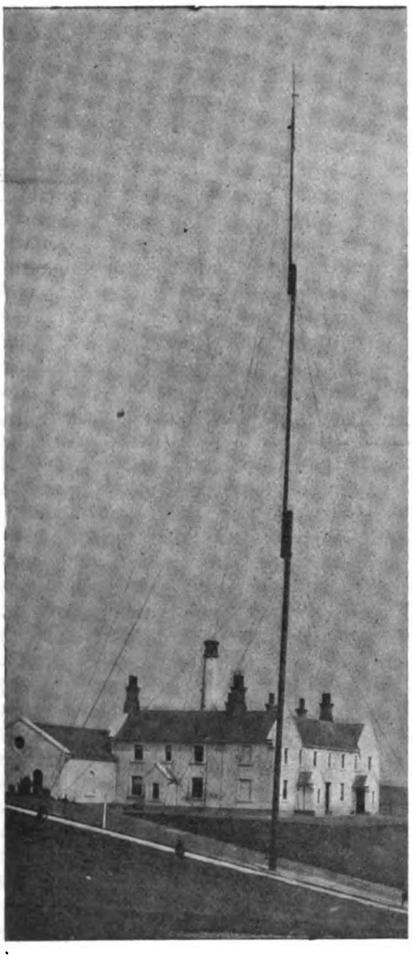
**Surface Contact System.**—In many of the cities in Europe the overhead trolley wires are objected to for aesthetic and other reasons, and more attention is therefore paid in those cities to the development of the other systems. The surface contact system is one of those which has rarely been installed, although probably a hundred systems have been invented. An installation of this kind which has just been completed in the city of Tours, in France, and is described in "L'Electricien," is therefore of interest. In this the Diatto switch is used. The total line is three miles, but on the part outside of the limits of the city the overhead trolley system is used. It was completed in April and is said to operate very successfully. It is said to be noted for the great simplicity and the reliability of its operation. The mechanism of one of the contact plates is shown in the adjoining illustration. The actual contact plate is the middle portion, C, on the lower side of which is secured a carbon block with a conical hole, which may be brought into contact with the movable plunger k, which is also mounted with a cap of carbon at the top. Whenever the car is over one of the plates this iron plunger, which floats in a tube containing mercury, is, by means of magnets on the bottom of the car, attracted so as to establish contact, and the moment the car has passed, the weight of that plunger breaks the contact again. The contact block is surrounded by a large block of asphalt S through which extend the soft iron pieces M; these form part of the magnetic circuit, as there are three bars or skates on the bottom of the car, the middle one being the north pole and at the same time the contact skate; while the two outside ones are south poles and their magnetism passes through the prongs M, to the hard rubber tube containing the mercury, and the plunger connection with the mercury is made by means of another mercury cup shown in the lower part of the cut, which is open only at the lower end and is connected with the feeder Q; the object of the latter arrangement is to prevent water from rising to the contact in case the pipe P should become filled with water. The contact plates rise only three-quarters of an inch above the surface of the pavement; the pipe P is for draining the opening; the cup A is of a non-magnetic material. The skate carried on the bottom of the car is composed of three bars, only the middle one of which makes contact, and is at the same time the north pole of a magnet; the two outer bars, which pass over the ends of the bent pieces M, are both south poles. The magnets are excited by the main current, but in order to start the car and to maintain contact if the current should be broken, a small storage battery is carried on the car, and its current flows continually through the exciting coils; this battery yields five to six amperes at 30 to 32 volts. Graphitic carbons of a very pure kind are used for the contact blocks and the contacts are said to be very good; there is said to be no sparking or arcing there, and as the carbon used is very pure the blocks do not stick together. The battery current continues to flow all the time except when there are long rests in the daytime or when there are no lamps lit in the car. This system has also been adopted for L'Orient and Reims, and it is also to be used on one of the lines in Paris.

THE DIATTO SECTIONAL CONDUCTOR SWITCH.

---

**Separating Foucault Current Losses from the Others in Dynamos.**—The efficiency of a dynamo is easily determined when all the losses are measured together, but some times it is desirable to separate the Foucault current losses from the others. A simple method for doing this was devised some time ago by Kapp, and is described incidentally in an article in the "Elektrotechnische Zeitschrift." The dynamo is excited with a constant current, and a current from a separate source is passed through the armature, running it as a motor. This is done for a number of different speeds, the more the better. When the speed in each case has become constant, the voltage and current in the armature circuit are measured, besides the speed. The products of the voltages and amperes give the amount of power required for overcoming all the losses, and of these the friction and hysteresis losses are directly proportional to the speed, while the Foucault current losses are proportional to the square of the speed in revolutions per minute. If, therefore, the watts obtained as above described are divided by the speed, the results will still be proportional to those losses; the numbers thus obtained are made up of a constant quantity, a, which is proportional to the internal losses, except those due to Foucault currents, and another quantity, by which is proportional to the Foucoult current losses, the air losses being neglected. By means of algebra, or by trial, or with the aid of a diagram, these quantities may then be separated. To do this by algebra use the equation

$$k = a + bv$$



in which k is the quantity obtained by dividing the watts by the speed. By substituting in this the values of k in two cases and the speed for the quantity v, the two equations may be solved for a and b, and by then multiplying a by the

Digitized by Google

speed v again, all the losses except those due to Foucault currents are obtained; and by multiplying bv by the speed v the Foucault current losses will be obtained, both in watts. The same results should be obtained from the data of any other two tests. To solve it graphically lay off the curve represented by that equation, k being the ordinates, v the abscisas. A straight line will be obtained cutting the k axis above the origin. The value of a is then equal to that distance, while b is obtained by subtracting a from any of the ordinates and dividing by the corresponding speed v.

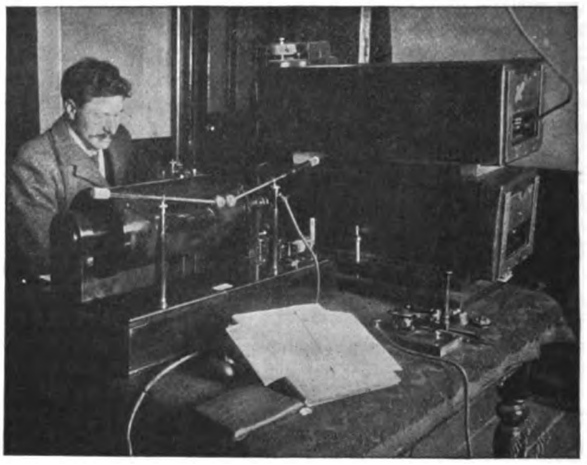
---

**Wireless Telegraphy.**—One of the great objections to the system of wireless telegraphy, about which so much is written at present, is that the electromagnetic waves sent out from the transmitter ex-

THE MAST AT SOUTH FORELAND.

tend in all directions like the sound waves from an explosion, and are therefore received by any and all of the other stations. Great confusion would therefore result if there was more than one plant in use. It is now announced in the English journals that Marconi has succeeded in devising what is called a selective system, that is in sending messages to any one of the four stations which now exist on the English Channel. Unfortunately it is not described how he accomplishes this, but it is of interest to know that he has actually succeeded in doing it in practice.

The accompany illustration, taken from the London "Electrician," shows the mast at the South Foreland station, which is required for the vertical wire, which seems to be the essential element of novelty in the Marconi system. This mast is 150 feet high and is intended for transmission across the English Channel in a place where the distance is 30 miles. He states that the height of these masts varies about as the square root of the distance, that is, for double the distance the two masts would have to be half again as high. He has found no difficulties due to the curvature of the earth, but does not know anything about the attempt which it is said will be made soon to telegraph across the Atlantic Ocean, nor does he approve of trying it at the present time. The apparatus of the South Foreland lighthouse is shown in the second illustration and will be seen to be surprisingly simple. The speed of transmission has now reached about 20 words per minute. Marconi agrees with the statement frequently made by others that his system is not likely to take the place of the usual telegraphy by wires for long distance commercial work, but its field is for telegraphing to islands, light ships or other places separated by the sea, and for this it is now available up to distances of 60 and 70 miles.



Marconi himself is quite a young man, being only twenty-five years of age. He was born in Italy, but his mother is English. When he first arrived in England with his instruments they were mistaken by the custom authorities for bombs or infernal machines and were broken up, thus rendering them quite useless.

---

The coherer, which is the detector of the electromagnetic waves used in wireless telegraphy, and which is the secret of the success of this system, is really quite a simple piece of apparatus, and it seems, from a recent experiment described by Prof. Blondel, in a note in the London "Electrical Review," that a coherer even better than that used by Marconi may be made by using alloys instead of mere mixtures; and moreover, that the best alloy is that of which the American nickel is made. One has, therefore, only to take a five-cent piece and file it in order to get what he considers the best knd of filings for a coherer. He also improved the instrument by making a side tube or pocket in the containing tube and filling it with these filings, the idea being that when those in use became fatigued by long action, the coherer may be freshened up by shaking it, so as to bring new filings into action.

---

**Long Spans of Overhead Wires.**—In calculating the strain and sag of wires, an approximate formula is generally used in order to simplify the calculations, but for long spans the error committed is too great. Prof. Juellig, in an article in our Viennese contemporary, the "Zeitschrift fuer Elektrotechnik," therefore calculated the data by the correct formula and obtains among other information the following figures giving the maximum spans possible for wires of different materials, on a basis of a factor of safety of four. For cast steel wire, 3.42 miles; for silicum bronze, 1.56 miles to 1 mile, depending on the quality; for wrought iron, 1.02 miles, and for soft copper, .53 miles. These maximum spans are independent of the cross section of the wire, for although the weight of the wire increases with the cross section, its strength increases in the same proportion. These spans do not allow for wind pressure, or for snow or ice, and the sag, being that to give the least strain, is quite great, in the case of the steel wire, for instance, it is 1.2 miles, and such a span would therefore be impracticable except from the tops of mountains. The figures are of value merely to show the possible limits.

THE APPARATUS USED BY MARCONI.

---

**Electric Automobiles in Paris.**—The first public electric vehicles have recently been started in Paris, and in course of another month it is expected that there will be 100 in use. The charging station and stables are designed for a capacity of 1000, and it is thought that in the course of a few years as many as 4000 will be in use. Some data and external views of these carriages are published in "L'Industrie Electrique," from which the following data may be of interest. To change the batteries for fresh ones at the stables requires only three minutes. The weight of a carriage which is intended for two people besides the driver, but will seat

Digitized by Google

two more by means of a folding seat, is 5000 pounds, including the useful load of about 600 pounds, which presumably refers to four passengers, the driver being included in the dead weight. The useful load is therefore only about 12% of the total weight to be carried. Pneumatic tires are used only on the front wheels, the rear wheels, which are larger, having cushioned tires. A battery of 44 cells weighs 1650 pounds and has a capacity of 135 ampere hours at a mean rate of 30 amperes, which corresponds to a run of about 30 to 36 miles; the positive plates are of the Plante type, and the negatives of the so-called chloride types. There is only one motor, with double windings on the armature and the field, that weighs 2112 pounds and develops 3 kw. at 1500 revolutions per minute. The changes of speed are all made by means of the different couplings of the two windings, the batteries being always in series. The steering is done by means of a vertical wheel, having a handle and operating by means of a worm wheel, the reduction being as one to fifty-two, which enables the steering to be done accurately, but requires very rapid handling for short turns.

**Water-Power Plant.**—A plant which differs somewhat from the more common ones in which water-power alone is used is illustrated and described in the London "Electrical Engineer;" it supplies light to the villages of Lynton and Lynmouth. The water-power is obtained from a river enabling a fall of nearly 90 ft. to be utilized, but during the dry season the quantity of water is not sufficient to carry the peak of the load, although all the power available during the twenty-four hours, if stored, would more than suffice. To get over this difficulty without the use of accumulators, a reservoir was constructed on a hill in back of the station nearly 800 ft. high. This holds 200,000 gallons and into this the water is pumped at the station during the hours when there is power to spare. The water from this reservoir is then used in high pressure jet wheels when needed. As the high tension alternating system is used, this appears to have been a simpler solution of the problem than if the energy had been stored in accumulators, which would have required the use of converters. It accomplishes the same thing as a dam across the river would have done, if sufficient water could have been collected during the day time, but this presumably was not practical in that case.

**The Use of a Third Brush.**—Sometimes it becomes necessary to rewind a dynamo in order to give double the voltage, and if it is a shunt wound machine it is tedious and expensive to rewind the magnets. Besides this the amount of the fine wire required would increase the cost still more. A method of avoiding the necessity of rewinding the magnets is briefly referred to in the London "Electrical Engineer," it being that invented some time ago by Mr. Sayers. It consists in using an additional brush placed on the commutator about midway between the other two; this brush is made of carbon and the field magnets are connected between it and the next main brush ahead of it in the direction of the rotation; the field will therefore be excited at a voltage equal to about half that of the dynamo; that is, by the original voltage, after that of the armature has been doubled by rewinding it. Strange to say, it seems that this third brush, which is, of course, not on the neutral line or even near, does not give trouble from sparking, and is found to work quite well; as it carries only a small current, the brush need only be quite small. An interesting property which this method has is that the machine will itself have almost a level characteristic because the main brushes are moved forward as the load increases, while the third brush remains in a fixed position, thus increasing the voltage between that third brush and the next main brush.

**Paralleling Alternators.**—Some of the difficulties encountered in paralleling alternators are overcome if an artificial load can be used so that the alternator to be switched into circuit can first be loaded with a separate load which can be thrown off gradually, as it takes its share of the useful load after coupling. The objection to this, however, is that such an artificial load is costly. A very cheap method, and one which it seems might be very satisfactory, was recently described by Mr. Dettmar in a German journal, and consists simply in a magnetic brake applied to the flywheel; the power of this brake may be adjusted quite accurately by regulating the current supplied to the magnets of the brake. It is applicable, of course, only to such alternators as have a flywheel to which the brake can be applied.

**Wehnelt Interrupter.**—The foreign papers still continue to describe further researches with this very interesting apparatus. A Frenchman named Bary, in the "Comptes Rendus," shows that there are three distinct stages in the actions of that apparatus. The first takes place when there is only a weak e. m. f. and there will then be simple electrolysis. As the voltage is increased the second stage sets in, and this is what might be called the useful one, as in that stage the current is being interrupted. With a still further increase in voltage the third stage starts, and in this the platinum becomes red hot and is surrounded by a layer of vapor. When there is no inductance in the circuit the second, or useful stage, does not exist at all, as the action passes abruptly from the first to the third, the point of transition depending on the dimensions of the platinum wire and the resistances in circuit. When an induction is inserted, interruption takes place, but the limits of the voltages between which it thus operates vary with the inductance and become wider apart as the resistance increases. What seems to have been a systematic investigation of the action of this interrupter was made by Prof. Hospitalier, of which he gives the results in a recent short paper in "L'Industrie Electrique." Briefly stated, he found the following: Other things remaining the same, an increase of the self-induction diminishes the frequency of the interruptions up to a certain value, when the interruptions start, and after this a steady current passes, producing simple electrolysis of the solution. On the other hand a diminution of the self-induction decreases the frequency up to a certain value, after which the action ceases, the platinum wire becoming red hot and allowing a constant but small current to pass. An increase of the voltage increases the frequency between certain limits. An increase of the diameter or length of the small platinum wire increases the current but reduces the frequency. By properly proportioning all the various factors which enter, the frequency of the interruptions may be varied between one per second and 2000. At low frequencies the interruptions are not sharp and decided, and the sparks are shorter. He also found that if the liquid is heated the required voltage will be lower than when the solution is cold.

Under the applications of this apparatus which he suggests, is a small electric welding apparatus for the use of jewelers and clock workers, which would be connected directly to the lighting circuits of a city. He gives no description of this, but the idea presumably is to place the interrupter in the lighting circuit and in series with the primary of a stepdown transformer, the low voltage secondary current from which is used for the welder.

A noted French writer, Prof Blondel, studied the action of this interesting instrument by finding the curves of the current and voltage, and he makes the interesting analogy that the action may be compared with a hydraulic ram, which, as is well known, will pump water to a greater height than that which operates it, of course, at the expense of some water which flows through it. This, he states, explains how the original voltage of the battery is apparently increased when such an interrupter is in circuit.

**The Magnet Known 44 Centuries Ago.**—Prof. Ewing, a noted English authority in a recent lecture remarked that it was said that a Chinese navigator named Hoang Ti as long ago as 24 centuries before Christ used a magnet for navigating a fleet of ships. This presumably was the first use of the mariner's compass. The form in which he is said to have used it was that of a fragment of lodestone, which was floated so as to be free to revolve. Lodestone, it will be remembered, is a natural magnet, consisting of the natural magnetic oxides of iron. The mariner's compass of Chinese origin was first brought to Europe in the 13th century by a man named Marco Polo. Notwithstanding these early uses of the magnet, the science of magnetism will be only 300 years old next year, as it dates from the publication of Gilbert's famous book in the year 1600.

# NOTES.

**The Annual General Meeting** of the American Institute of Electrical Engineers will be held at the Massachusetts Institute of Technology in Boston on June 26, 27 and 28.

**The Independent Telephone Trust.**—The promoters of the proposed consolidation of telephone manufacturing interests failed to perfect their organization before May 1, when the options they had obtained expired.

**Canadian Electrical Associations.** — The Maritime Electrical Association held its second annual convention in Halifax, Nova Scotia, Tuesday, April 18. The Canadian Electrical Association holds it next annual convention at Hamilton, Ontario, the 28th, 29th and 30th of June.

**An Electrically Lighted Royal Train.**—An English railway company has recently completed a train for the use of the Royal family at a cost of some $40,000. It consists of five cars, all of which are electrically lighted from one axle-driven generator, supplemented by a storage battery in the baggage department.

**Experiments with Wireless Telegraphy in Chicago.**—Mr. Arthur V. Abbott, Chief Engineer of the Chicago Telephone Company, gave an address on wireless telegraphy, illustrated by experiments, before the Y. M. C. A. Electrical Club on Friday, May 12. The results of the experiments were rendered perceptible to the whole audience by connecting the coherer circuits with incandescent lamps and electric bells to give visible and audible indications of the transmission of the waves.

**A New Building for the Franklin Institute.**—The Franklin Institute of Philadelphia is considering the erection of a fire-proof structure in which its valuable library and collection of documents and manuscripts can be kept. Like the scientist by whom it was founded and for whom it is named, the Institute has been prominent in both the scientific and practical aspects of electrical engineering and has many valuable original documents relating to this field.

**The First United States Government Cable Ship.**—A cable-laying and repair ship has been fitted out for service in the Philippine Islands by the United States Government, the ship being one captured from Spain and since used as a transport under the name of "Hooker." As reconstructed, the ship contains 3 cable tanks with a total capacity of about 700 tons of cable. The equipment also contains the usual paying-out and winding-in machinery and cable testing instruments. The ship is 333 ft. long with about 2000 tons displacement and is driven at a speed of 13 knots by a 1600 h. p. engine.

**The Combination of Copper Producers.**—The present high prices of copper are likely to continue if the plans of the recently organized Amalgamated Copper Company are carried out. The company was incorporated with a capital stock of $75,000,000, which was immediately subscribed some four or five times over at par value when the subscription lists were opened to the public. The officers include Wm. J. Rockefeller and others of Standard Oil fame. The company has taken over large interests in the Anaconda Copper Company, as well as other properties in Montana, and will, if rumors are verified, obtain control of all the Michigan copper mines and the United Verde mines in Arizona.

**The American Electrician in Japan.**—The accompanying set of characters are a reproduction of a notice in the Japanese "Electrical Friend," a monthly electrotechnical journal published in Tokyo. The translation is as follows: "The American Electrician, New York, issued monthly, at a subscription of $2.00, including postage, is devoted to American practice in electrical engineering. Electric lighting, the electric railway, the telephone, telegraph, practical operation and everything concerning electricity are ably treated in richly illustrated articles. Apply to the

THE AMERICAN ELECTRICIAN IN JAPAN.

"Electrical Friend," Tokyo, which has special arrangements with the American Electrician.

**Another Combined Electrical Exhibition and Convention.**—The exhibit features of the convention of the American Street Railway Association have extended to such a point that this year their interest to the public in general will be recognized and made profitable by establishing an electrical exhibition to be open from September 25 to October 9, immediately following the convention. There has been incorporated the National Exhibit of Electrical Arts Company with an authorized capital of $50,000, to take charge of the exhibition.

**The Earnings of the Chicago-Edison Company.**—The annual statement of the Chicago-Edison Company for the fiscal year ending March 31 shows a gross income of $1,954,877, an increase of 17 per cent. over that of last year. Of this $1,214,621 was absorbed by the operating and other general expenses, leaving a net income of $740,256, of which $262,524 was paid out as interest upon the $4,808,000 of bonds and debentures outstanding and $396,072 was paid as an 8 per cent. dividend upon the outstanding capital stock.

**Removing a Large Chimney.**—An economical means of bringing down the brick of a large stack 266 feet high and 21 feet in diameter is described in "Industries in Iron." The brick was removed from one side at a heighth of about 3 feet from the ground and replaced by built-up wooden blocks, between which were packed tar, sawdust and paraffine, which were then set on fire. The chimney was thus made to fall in exactly the line marked out for it on the ground. The cost was only half of its removal by throwing the brick down and considerable material was recovered for future use.

**Alternating Waves Checked by Zinc Vapors.**—In a paper recently read before the English Institution of Electrical Engineers there were described experiments made with alternating current arcs between carbon and an alloy of zinc. In this case the current is purely unidirectional, the waves or half cycles of that polarity which would make the zinc the positive electrode being entirely suppressed. The action is the same as the phenomenon turned to practical account in this country in the construction of non-arcing lightning arresters, the vaporization of the zinc practically forming an insulating sheath.

**The Lighting of the Greater American Exposition.**—The remarkably beautiful illuminating effects obtained solely with incandescent lamps on the court of honor of the Trans-Mississippi Exposition at Omaha last year will be exceeded this year in the Greater American Exposition which is to open July 1 on the same grounds and using the same buildings. Over 15,000 new lights are being placed on the main buildings alone, to further outline their graceful proportions. The same general principle will be adhered to of obtaining a harmonious effect by uniform brilliancy, no arc lights being allowed to disturb the softer glow of the incandescent.

**Electric Traction on the Main Railroads in Italy.**—Owing to the absence of coal in Italy and the consequent extensive use of water power, the government contemplates the adoption of electric traction on the Italian railroads, which are nearly all government property, although leased to operating companies. One of the largest railway companies has recently put in service an accumulator equipment on its line between Milan and Mon-

Digitized by Google

xa, a distance of eight miles. The cars are fitted for 100 passengers and run at a schedule speed of 25 miles per hour. They are fitted with accumulators sufficient to run for 43 miles on a level track. Other experiments are shortly to be made with the third rail systems and possibly with induction motors and high tension transmission.

---

**The Litigation on the 3-Wire Patent.**—The motion for a preliminary injunction brought by the General Electric Company against the Imperial Electric Light, Heat & Power Company of St. Louis has been denied; the opinion of the court being based on the fact that there has been no adjudication by any court of the validity of the 3-wire patent, and no such general acquiescence in the rights of the patent as to justify the injunction. This inability to obtain a preliminary injunction practically throws the use of 3-wire systems open to the public, as the patent expires within one year's time, subject, of course, to the possible collection of claims on the part of the present owners for the unexpired term of the patent in case of a final decision upholding its validity.

---

**Railway Motors to Be Manufactured in England.**—Hitherto there has been no concern engaged in the construction of railway motors in the British Isles, but a syndicate has recently been formed by Dick, Kerr & Company, the well known contractors, for the manufacture of dynamos, motors and controllers for electric railway purposes only. The designing will be entirely in the hands of the well known American engineer, Mr. Sidney H. Short, whose work was a strong element in the rapid growth of the enormous business recently handled here by the Walker Company. The English syndicate has been formed with a capital the equivalent of $1,000,000, and will build a factory in Preston, which will be equipped with apparatus a large part of which was purchased in this country on a recent visit of Mr. Short and Messrs. Geo. Flett and T. S. Turnbull of the syndicate, all of whom sailed for England on May 6th.

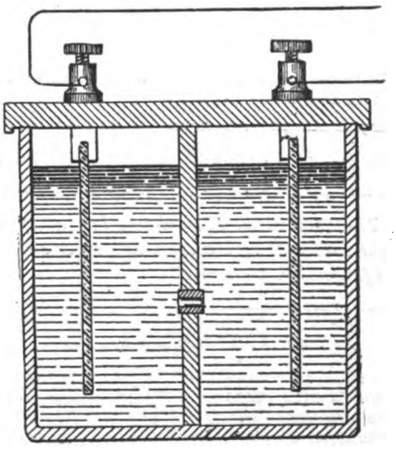
---

**Novel Engine Governing.**—A 1200 h. p. Willans engine which is being built for the Liverpool street railway is fitted with a combination of throttling and cut-off variation unknown on this side of the water. The governor normally controls the speed by throttling, but the engine is designed for a considerable overload capacity, owing to the fact that it is to be uesd in traction work, and the dynamo to which it is to be coupled will be capable of standing such an overload for short periods of time. If the speed continues to fall when the throttle is full open the governor opens a valve, which admits steam to a relay cylinder, which controls a linkage, lengthening the cut-off. If this is not sufficient the relay cylinder finally opens a set of by-pass valves, which allow high pressure steam to enter the low pressure cylinders, the engine working single expansion on all cylinders, instead of compound, until the overload is removed.

---

**A Curious Dam Failure.**—On the morning of April 30th a section of masonry 175 ft. long of the upper dam of the St. Anthony Falls Water Power Company of Minneapolis, Minnesota, was overturned in quite a remarkable manner, if the theories by which the accident is accounted for are true. The pond back of the dam is 300 ft. in width and during the last winter, which was extremely cold, the ice formed to a thickness of about 6 ft., clinging to the shore on one side and the dam on the other and rising and falling in the middle as the water level changed with the demands of the various mills supplied from the pond. It is supposed that when the water fell the ice would sag in the middle and crack, and these cracks would fill and freeze, forming a long inverted arch which, when the water rose again, would act like a mammoth toggle joint and exert an enormous horizontal force against the dam. The various manufacturing interests using power from this fall must depend in part on their auxiliary steam plants until the break can be mended; among these are the Minneapolis General Electric Company. The extensive plant of the Twin City Rapid Transit Company, recently described in these columns, obtains its power from another dam further down the river.

---



**The Classification of Electrical Freight.**—The committee of the National Electric Light Association appointed to effect some readjustment of the freight classification on electrical merchandise reports that it has received from the official classification committee of the railroad companies a reply from which the following is an extract:

"I have to advise that the subject was presented to the classification committee for consideration, but after careful deliberation the committee did not deem it expedient to recommend any change in the classification of this class of property."

It is the desire of the committee of the National Electric Light Association that all manufacturers and others interested in tariff changes have some one present at the convention to be held at Madison Square Garden, New York City, May 23-25, who will meet with the committee with the idea of taking some vigorous steps calculated to bring about a just and equitable tariff. It is apparent, and has been for some time, that ordinary appeals to the railroad organization as represented by its classification committee will prove inadequate to accomplish the desired end. An announcement will be made on the opening day of the convention of a time and place for a special meeting to be held with the committee on this particular subject, during the session of the convention, that steps may be taken other than the usual resolutions that follow a committee's report. Every central station in any large city, or any considerable user of electrical apparatus, as well as every electrical manufacturer of heavy machinery and electric lamps, should be sufficiently interested in this subject to have some one in attendance at the convention to advise with the committee in carrying out the object for which it was created.

---

**A New Liquid Interrupter.**—Mr. E. W. Caldwell of New York has communicated to the "Electrical Review" a description of a liquid interrupter, resembling that associated with the name of Wehnelt, but differing therefrom in that both the terminals of the interrupting gap are liquid. A preferred form of the apparatus is shown in the accompanying illustration, reproduced by permission of the "Electrical Review," where it will be seen that two electrodes dip into liquid in two chambers respectively, which are connected only by a small aperture at which place the interruption takes place. Another form of insulating partition con-

A LIQUID INTERRUPTER.

sists of an ordinary test tube having a small hole in its side. The communication referred to also shows photographic reproductions of the high tension spark discharges from induction coils provided with this interrupter, which resemble closely previously published photographs from high tension alternating current transformers operating at 150,000 volts or thereabouts. Mr. Chas. T. Child has also published in the same periodical an account of experiments performed with this new interrupter. Upon operating it with a current of about 6 or 7 amperes at 110 volts, the pressure rises to such a heighth across the interrupter that an incandescent lamp shunted around it is immediately blown to pieces with a sharp report. The same writer gives also the comparative effect on an induction coil of both the Wehnelt and Caldwell instruments; when the former is used the secondary discharge appears as a roaring arc across the terminals, while the latter gives a discharge with the appearance of a shower of blue sparks of great energy.

**The Electric Light Convention.**

The twenty-second annual convention of the National Electric Light Association, which convenes in Madison Square Garden May 23d, will be chiefly notable, so far as can be determined in advance, for its combination with the electrical exhibition. Of late the exhibit features at the electric light conventions have fallen off until they have become far less elaborate than the corresponding features of some other annual meetings, such as that of the American Street Railway Association. This year the exhibits will be more extensive than ever before.

The list of papers includes two by those well-known speakers at previous meetings, and notably at the last convention, Messrs. Herbert A. Wagner and Louis A. Ferguson, although this year their subjects are not likely to excite the animated discussion which the subjects of last year did. These and other papers exhibit a notable leaning toward the rather exceptional installations of the largest cities as opposed to the average central station of the medium sized city. Undoubtedly the methods of working used in the larger metropolitan plants are more scientific and represent better engineering than do those of the smaller systems, but the latter plants are often prevented from using them by the inability of their comparatively small loads to make any returns on such expensive equipments, making their problems more perplexing than those of the large plants.

Of the eight papers announced, six, including the two mentioned above, are by men immediately engaged in central station work. One is by Prof. C. E. Robb, of Hartford, Conn., treating of the valuable experiences gained in the notable Hartford transmission plant, and the eighth is by Mr. W. R. Emmet, on the safety devices in electrical distribution, a vital subject which he is fully competent to discuss owing to his extensive experience in the Niagara and other systems handling large powers at high voltages and through many transformations.

**Arc Lights from Alternating Generators.**

In the attempt to do away with the large variety of generators which have been common in the central stations of the last decade, three general systems have been developed for supplying series arc circuits from alternating current generators simultaneously used for incandescent and motor loads. One of these consists simply in driving ordinary series arc dynamos by alternating current motors. A notable installation of this kind, constituting as it does the electrical transmission of power at 2000 volts for a distance of 20 ft., is that of the Boston Electric Light Company, a description of which will be found on other pages. This plan only in part does away with the disadvantages of the conventional arc system, which are excessive floor space, attention, losses and the general complication of many small units. To be sure, the belting and shafting is done away with, but the arc dynamo remains with all its disadvantages.

Another plan involves the use of rectifiers, which have not as yet been commercially used in this country, although one machine for 25 cycle multiphase circuits has been perfected, and may be soon on the market. There will be found on another page descriptions of English apparatus of this kind for working series arcs from 60 cycle single-phase alternators. The rectifier reduces greatly the first cost, floor space and losses of the motor generator combination.

The third method involves the use of alternating currents in the lamps themselves, the series circuits being fed through transformers designed to automatically regulate to give constant current from the constant potential primary. The first cost of such a system is lower than of either of the others, but the efficiency is some little less, owing to the lower economy of alternating current arcs, although this disadvantage is probably small in the enclosed form of lamp. In common with the rectifier it throws a considerable lagging load upon the alternating current machinery, but it differs from the rectifier in requiring practically no attention.

**Some Possible Limitations of Wireless Telegraphy.**

The remarkable series of experiments recently carried on by Signor Marconi in England have indicated that ether-wave telegraphy has possibly such a large field of usefulness that they have even occasioned no inconsiderable drop in the market quotations of the stock of telegraph and cable companies. At present so little is known about the behavior of the ether waves that it is impossible to foretell with any certainty whatever what the new system of signalling may develop, but a few of its possible limitations can be laid down.

Digitized by Google

It is obvious that for any extended use there must be found some system of shielding any receiver from the influence of all other transmitters but the one to which it is supposed to respond. Otherwise, the use of one transmitter, with a range of—let us say—100 miles, would prevent the transmission of any other signals in a district with an area of some 30,000 square miles. To be sure the general distribution of intelligence from one central source might be made useful in press service, and it is easy to picture a central transmitter at some such point as London sending, without a single wire, general news and intelligence to all points in the British Isles where coherers are set up. It should be noted, however, that the available speed at present is rather low for such service, being given by the English publications as only 12 to 18 words per minute. If the very limited experience obtained in this country is any guide, this is due to the confusion arising from the intermittent action of the induction coil and the liability of mistaking the chattering of the coherer in time therewith for Morse dots unless the latter have a time duration considerably greater. This may be remedied by the use of higher frequencies derived from alternating currents, Wehnelt interrupters or other devices.

---

It is self-evident that there are only two general ways of limiting one receiver to the messages from its own transmitter. One is by means of reflecting, focusing or concentrating the waves and the other by syntonizing or tuning the receivers and transmitters in pairs to different frequencies. The first method depends upon the transmission of the waves in rectilinear lines like rays of light, which does not appear to hold true, the transmission being apparently more like that of waves of sound, and capable of infinite deviations from a direct course. At any rate such focusing would be impossible at any great distance owing to the curvature of the earth and the fact that the latter is an effective shield. As for syntonizing, it is probable that only a few instruments could be worked in one locality by this method, as but one or two octaves would be available owing to the influence of odd harmonics upon their fundamental, and past experience with harmonic telegraphy gives some indication of the number of different frequencies which could be isolated in one octave.

As for the distance of transmission, a wire about 180 ft. high is said to carry effective signals 16 miles, the distance varying as the square of the height. This may be increased somewhat by the use of greater power in the transmitting apparatus, but this figure gives a rough idea of the necessary height for long distance transmission.

---

**Features of English Central Station Practice Worthy of Imitation.**

To the central station engineer the study of foreign plants is second in value only to that of stations more nearly representing his own work in this country. Among the latter he finds exactly his own conditions, and the way in which others have met them as developed under the influence of the prejudices and habits of mind and of engineering peculiar to this country. The wide awake engineer, who wishes to forestall so far as possible the coming changes in electrical engineering, and thereby not only increase the economy of his plant but greatly reduce its depreciation by installing apparatus some years ahead of the times, must feel the need of watching what other nations are doing with their contemporaneous developments along lines differing from ours owing to racial characteristics, and who are likely, therefore, in some lines, to have found methods, systems or details superior to our own.

---

On other pages there will be found descriptions of those features of some English central stations which strike the mind of an American observer as of interest owing to the contrasts they strike with corresponding American methods. One of the greatest of these contrasts is the extensive use of 450 volt 3-wire systems using 220 volt lamps, something quite unknown in this country. Indeed, so firmly has the idea become established that 225 volts is as high a pressure as should be allowed on interior incandescent lighting that probably no little difficulty would be encountered in establishing such a system. Two hundred and twenty volt lamps have during the last two years come into no little use in this country on 2-wire systems for two purposes, one the distribution of current over considerable areas without the losses of alternating current distributions, and the other the lighting of buildings fitted with isolated plants and with what is known as the "break-down" service on Edison mains, but it is generally considered that a sacrifice of some 15 to 20 per cent. must be made in the economy of the lamp in order to utilize a higher voltage. In other words, if the regulation is such that a 3.1 watt lamp can be used on a 110 volt system a 3.6 watt lamp must be used on the 220 volt system. This is probably the case under the existing conditions of lamp manufacture and voltage regulation in this country. In England it seems to be customary to use lamps of the same economy on the higher voltage as on the lower and to sacrifice somewhat the life of the lamp. Probably the same could not be done here, as with the poorer regulation customary in this country the high economy high voltage lamps would be burned out during the first few hours of their life.

---

One effect of the high voltage upon the lamp circuits in England has been the development of fittings of a much more substantial and highly insulating character; particularly is this true of sockets which are not of the flimsy stamped sheet brass type known here, but are of a much more rigid and substantial character.

---

**Circuit Breakers for Flat Rate Customers.**

The development of a small and cheap circuit breaker designed to open on from 5 to 25 amperes has brought up the possible application of an instrument of this class to prevent flat rate lighting consumers from imposing upon the central station by applying a load greater than that for which they are paying. The comparative accuracy and generally more dependable qualities of the breaker would allow a closer check to be obtained upon the load consumed than can possibly be had with such a crude device as a fuse. The application of such an instrument would probably please the consumer as it would enable him to re-establish his circuit without bothering with fuses or without the delay of sending word to the central station, and in this way also considerable time of the station employees would be saved. The main objection to such a course is the temptation for the consumers to change the adjustment, add weights to the armature or tie the blades of the breaker in the closed position. It might be well for circuit breaker manufacturers to design an instrument enclosed in such a way that it could not be tampered with, somewhat on the general principle of the "pop" safety valve.

## THE DESIGN OF A SINGLE PHASE RECTIFIER.

BY J. C. BROCKSMITH.

The idea of rectifying alternating currents is not a new one, and it has already been applied to a considerable extent in English alternating current supply stations, where Ferranti rectifiers are used in connection with constant potential to constant current transformers for supplying a unidirectional current to arc lamps. Such an apparatus has a high efficiency, and it has the further advantage of occupying much less space than arc machines to do the same amount of work.

In this country the Brush and Thomson-Houston arc machines furnish familiar examples in the rectification of alternating currents, the former being virtually a two-phase generator with a rectifying or "two-part" commutator, and the latter a Y-connected three-phaser with the free ends of the Y connected to three commutator segments for producing a unidirectional current in the external circuit.

In addition to these instances there are many alternating current generators, both single-phase and polyphase, which are compounded for constant potential by means of a rectified current taken from the main winding and led through series coils on the field magnet.

The rectification of alternating currents is thus a perfectly practical operation, where the apparatus for accomplishing it has been designed with due regard to the principles involved, and to the somewhat exacting requirements of the case.

A little thought will show that no alternating e. m. f. can be rectified into a perfectly uniform direct e. m. f., although this can be approximated more closely as the number of phases is increased. Thus a single phase e.m.f. when rectified has a considerable amount of pulsation, a two phase e.m.f. will have less, while a rectified three phase current will be about as constant as is necessary for practical purposes.

While a rectified single-phase e. m. f. has this fluctuating character, it is not very objectionable, especially when working with a load having little or no self-induction, such as arc lamps or storage batteries. In fact it has been stated that a certain amount of fluctuation in the current in these classes of work is somewhat of an advantage.

The more important requisites for a rectifier are: (1.) It must always run in exact synchronism with the generator which is supplying the power. (2) It must not fall out of step easily nor be in the least disturbed by a draft of current from the direct current side. (3.) Its armature must not only maintain synchronous speed, but must also keep a constant and correct angular position within the revolution. (4.) It should preferably be self-starting and self-exciting, and (5.) It should not require constant attention nor be subject to serious sparking, or wear and tear.

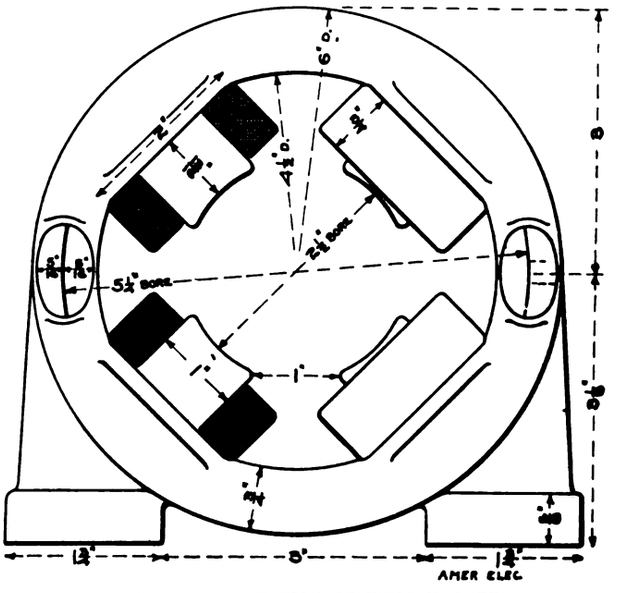

FIG. 1.—END ELEVATION OF FIELD MAGNET.

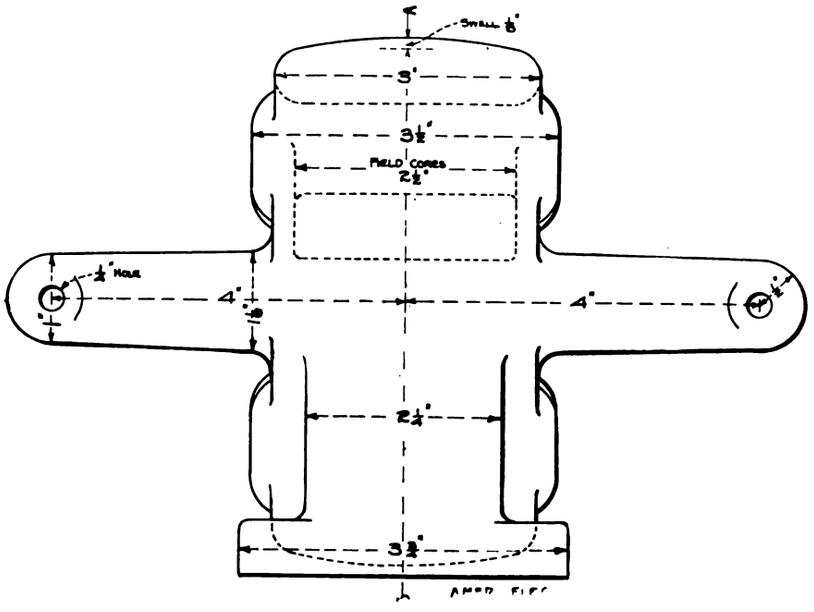

FIG. 2.—SIDE ELEVATION OF FIELD MAGNET.

The first requirement is best met by designing a regular synchronous motor to do the work of driving the commutator and collector rings. The writer has experimented with different forms of induction motors designed with a view to securing a more or less pronounced tendency to run in synchronism, and though such machines are self-starting, the tendency to remain in step is somewhat weak and a variation in the voltage of supply will throw the machine out of step and cause bad flashing at the commutator.

The second requirement is met by providing a toothed armature having one tooth per pole, and giving this a small mechanical clearance. Such an arrangement gives a strong synchronizing power.

The third requirement may be met by running the machine at a constant load, and by providing a considerable amount of inertia in the armature by means, let us say, of a flywheel on the end of the shaft. This will entirely prevent a very objectionable surging action which would otherwise occur.

When the armature is running free and no flywheel effect has been provided, there will be an oscillation to and fro all within the space of a single revolution, which will react on the current, causing this to fluctuate also; the effect then grows rapidly worse and finally throws the armature out of step. By putting a mechanical load on the machine or letting it drive the armature of another machine, the same result can be obtained as with a flywheel.

About the fourth requirement it may be said that it is not so important to have a self-starting machine when it is to be used in a laboratory and can be conveniently started by some outside means. It can easily be made self-exciting by connecting the field terminals to the direct current brushes.

Self-oiling bearings and spring brush holders will answer the fifth requirement and give a machine which will run for considerable periods of time without any attention whatever.

Let us now turn to the working drawings and see how a single-phase rectifier can be constructed.

Digitized by Google

Fig. 1 shows an end view of the field magnet with coils in place, two of which are represented as cut away to show the shape of the poles and cores.

The circular yoke, poles and arms for supporting the bearings are cast in one piece, thus avoiding joints in the magnetic circuit, and reducing the machine work to a minimum. The pattern for the field casting should be made in two pieces, the parting being made along the line AB in Fig. 2.

The field casting is mounted on the face plate of the lathe—one of 9 ins. swing will do—and the poles are bored out to the required diameter, 2½ ins., at the same time the arms for the bearings are finished to the arc of a circle 5¼ ins. in diameter. These may, however, be filed and fitted by hand, if this is more convenient, but the method of boring is the more accurate.

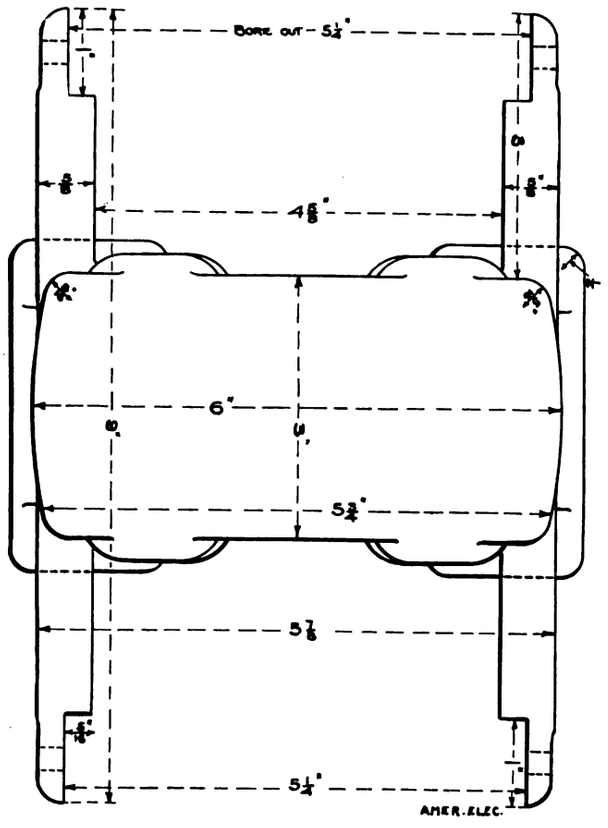

FIG. 3.—PLAN OF FIELD MAGNET.

Fig. 4 shows a section through the armature, commutator and bearings. The armature core is built up of laminated iron in the usual way, and held together by heavy washers of wrought iron threaded on the shaft at either end. A cast-iron core may be used, though it will, of course, heat up more than the laminated one.

The commutator and collector rings are turned as a solid cylinder of the required section, and it is then cut into four equal segments with a milling machine, or with a sharp hacksaw and hand power, if a milling machine is not available. The segments are then built up with mica insulation and clamped in a brass sleeve fitting the shaft.

It is well to follow the design of arc machine commutators to some extent and to allow about 1/16 in. air insulation between the segments at the top. Thus the mica insulation will not be injured if sparking occurs. Oil and copper dust should not be allowed to accumulate in the air spaces thus formed, as this would cause a severe short circuit.

Connections are made between the collector rings and commutator bars with some strips of copper about 1/32 in. thick and ⅜ in. wide, laid in the armature slots, which have been made about 1/16 in. wider than would otherwise be necessary in order to accommodate both the coils and the connection strips. The back collector ring is drilled with ⅛ in. holes at four equidistant points, two of these holes, the opposite ones, go through the ring and part way into the front ring, the other two holes are drilled only part way in. Some short pieces of copper wire, about No. 10, are soldered one into each hole, the two wires from the front ring being insulated from the other ring where they pass through it. The four wires are soldered one to each strip, and these carry the current across the armature and connect to the commutator segments.

Diametrically opposite segments of the commutator are thus connected to the same collector ring, and neighboring segments have between them the whole po-

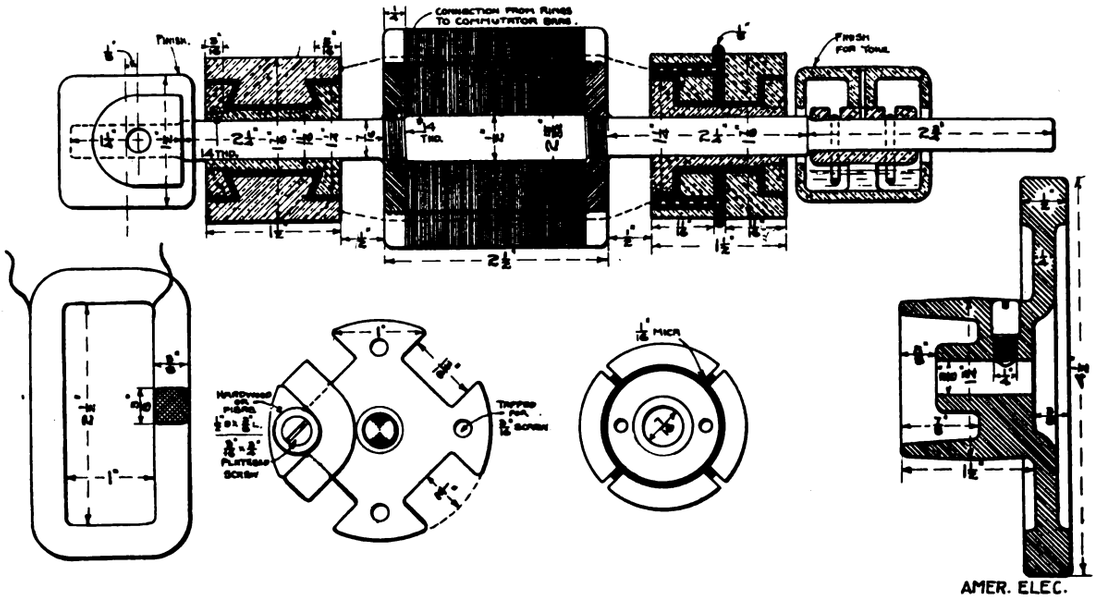

FIG. 4.—SECTION OF ARMATURE AND DETAILS OF CORE, COMMUTATOR AND PULLEY.

preferably made of copper, though brass may be used. A piece of ingot copper can be obtained and forged into a circular blank suitable for turning up into rings and a commutator. The commutator is

tential difference of the alternating circuit.

It is better not to connect the copper strips permanently to the commutator until the builder has decided where he

Digitized by Google

wishes to place the brushes; the commutator may then be twisted around on the shaft to the correct position and the connections made permanently. The brushes may be placed wherever they will be most convenient, the only restriction being that they must be 90° apart and must pass from one segment to the next at the same instant that an armature tooth is exactly under a pole.

A detail in Fig. 4 shows the method of placing the armature coils upon the core. The coils are wound on a form, and, after being taped, are slipped over the top of a tooth. The slack is then taken up by bending the ends down in a semi-circular shape and fastening them in this position by screws which carry small fibre or hardwood bushings.

In addition to this the armature should be banded at one or two points with No. 28 brass or German silver wire, small notches having been turned in the core to receive the bands and allow them to come flush with the surface of the core.

With an iron-clad armature like this, the clearance need not be more than from 1/64 in. to 1/32 in.; just how much it will be depends somewhat on the builder's skill; 1/64 in. clearance has been indicated on the drawings, and with care taken in adjustment it should not be difficult to obtain this figure.

Fig. 5 shows the bearing, brush yoke and brush holders. The bearings, while not so simple in construction as some other designs, have proven very satisfactory. The rings carry up a plentiful supply of oil, and what runs out at the end returns to the well and does not fly off outside the bearing and spatter the surroundings with grease spots.

In finishing the bearings the cap is first fitted and fastened by two machine screws. The bearing is then placed in the chuck and bored out to a diameter of ⅝ in. clear through. At the same time the ends are turned off 5¼ ins. in diameter to fit the arms on the field casting, and the outside of the boss is turned off 1½ in. diameter where it is to receive the brush yoke. The sleeve which forms the bearing proper is turned a tight fit for the central part of the box, then when the cap is screwed down it will be held firmly in place. The grooves for oil rings can be cut in the sleeve conveniently by mounting it eccentrically in the chuck and using a thin cutoff tool.

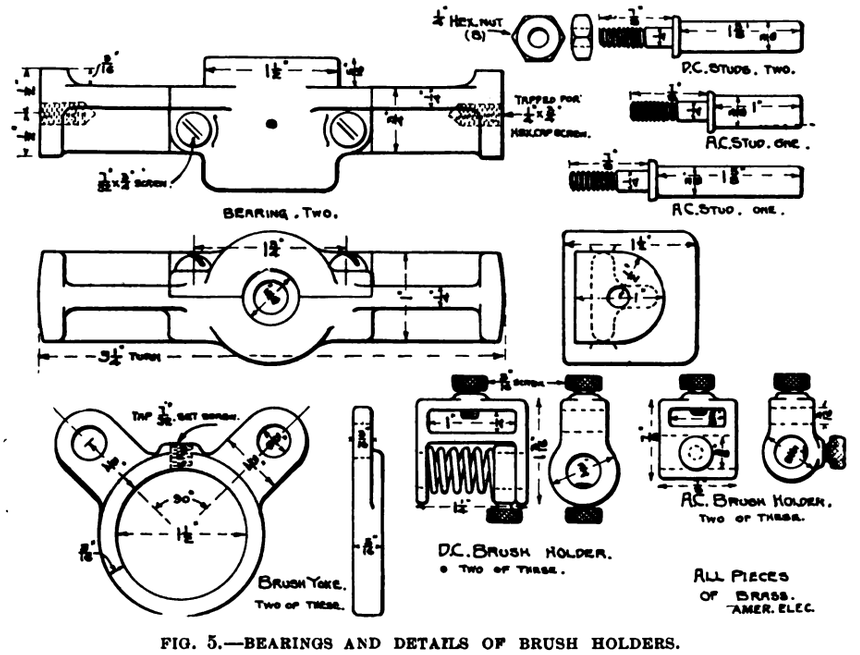

FIG. 5.—BEARINGS AND DETAILS OF BRUSH HOLDERS.

The brush yoke is shown with two arms 90° apart. Another pair of arms and brushes might be added if it is desired to have more current carrying capacity.

The direct current brushes had better be larger than the alternating current brushes, and the holders should have spring tension, unless a very springy brush is used. Copper brushes are better for this purpose than carbon, as they make better contact and cause less sparking.

Fig. 6 shows the field and armature coils and the forms upon which they are wound. The former is best made of hard wood, and consists of a block and two flanges, all held together by two wood screws and having a ½ in. hole through the center for placing on a mandril in the lathe. The block should be made a trifle larger than the pole over which the finished coil is intended to go, and it should be given a slight taper of about 1/16 in., so that it can be readily slipped out of the finished coil.

Before beginning the winding a short piece of tape is laid in the long sides of the former, with the ends left sticking out. When the form is wound full these pieces of tape are tied tightly over the coil, and will hold it in shape while the former is taken apart and the coil is receiving its wrapping of tape. After being shellacked and dried, the coil is placed on the poles and hard wood wedges driven in between coil and pole, thus holding it securely in place.

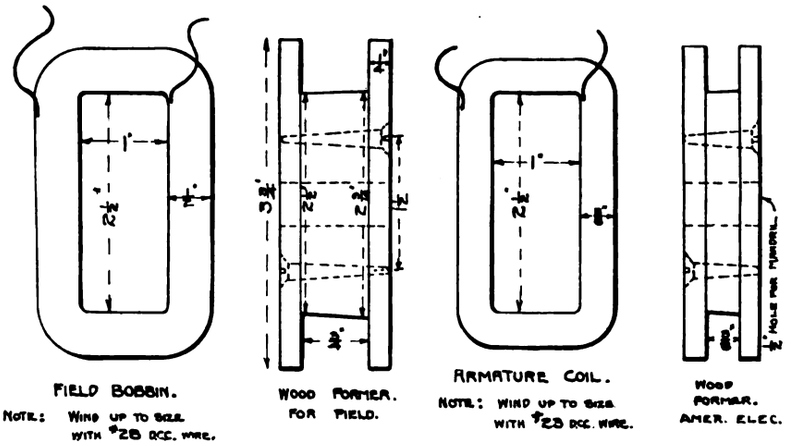

FIG. 6.—ARMATURE AND FIELD COILS AND FORMERS

The same form may be made to serve for both field and armature coils, if the field coils are wound first, and then the block reduced in thickness from ¾ in. to ⅝ in., the armature coils having the same inside dimensions as the field coils, but being only half as thick.

The fields are wound with No. 28 double cotton covered wire and the armature with No. 23. If the coils are wound to the specified dimensions they will have nearly enough the required number of turns.

Fig. 7 shows a diagram of connections and some e. m. f. curves. For 100 volts the field and armature coils are connected four in series, as shown. For 50 volts the coils may be connected two in series and the twos in multiple. The armature terminals are tapped onto the collector rings, or what amounts to the same thing, placed across any two successive commutator segments.

The connections on both armature and field should be such as to produce alternate north and south polarity all the way round. If all the coils have been wound in the same direction and placed on the poles the same way, connect beginning to beginning and ending to ending, and the polarity will be right.

This being a four-pole machine it will run 1,800 r. p. m. on a 60-cycle circuit, and on a 125-cycle circuit it will have to make 3,750 r. p. m. This it can easily do if the armature is well balanced as it should be.

Since the strength of the field has a con-

Digitized by Google

siderable effect on the behavior of a synchronous motor, it is best to have an adjustable resistance in the field circuit of this machine, so that the field can be adjusted until the minimum armature current is obtained.

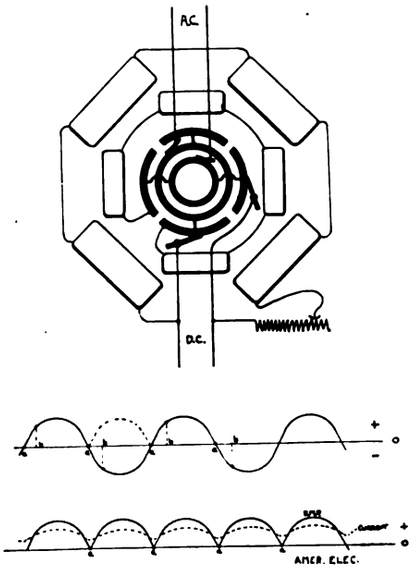
Referring now to the curves in Fig. 7, it is clear that if the rectifier is running in synchronism and the angular position of the brushes is correct, the brushes will pass from segment to segment at the instant when the e. m. f. curve reaches its zero value at the points, a, a, a, etc. As the brushes in passing from segment to segment overlap two segments for a brief interval, they form a dead short circuit on the alternating current mains during the interval. This will not, however, result in any damage if the e. m. f. becomes zero at the same instant. If, however, the brushes had been incorrectly placed and commutation occurred at the points b, b, b, etc., an e. m. f. of value equal to the ordinate at b would be short circuited four times in a revolution, and serious sparking would result.

This state of affairs is easily remedied by shifting the brushes, which corresponds to changing the angular position of the point of commutation until a position such as a a is reached, when all sparking will disappear.

If the armature falls out of step, or if it is thrown into circuit before complete synchronism is reached, a short circuit travels over every portion of the e. m. f. wave, at a slow rate equal to the difference between synchronous speed and the actual speed at that instant, the result being a magnificent display of fireworks and probably a fuse blown.

To obviate this latter difficulty a resistance or choking coil should be placed in series with the alternating current end at the moment of starting, and cut out when it is seen that the machine has settled down to steady running. Such a resistance will not have any appreciable effect on the small current drawn by the armature and field windings, but should be of such a value as to limit the current to about 10 amperes, should a short circuit occur.

The ordinary method of a synchronizing lamp is not easily applicable here on account of the small size of the machine; and, moreover, a little practice will enable the operator to judge by ear the proper instant for closing the circuit.



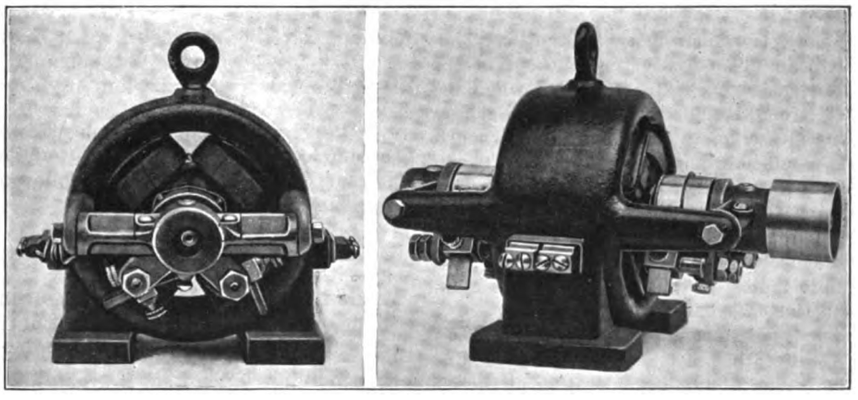


FIG. 7.—DIAGRAM OF CONNECTIONS AND E. M. F. CURVES.

Thus by making slight changes in the connections, as already pointed out, this machine may be used as a rectifier on single-phase circuits of 50 or 100 volts and 60 or 125 cycles. The amount of rectified current which may be drawn is not limited in any way by the horse power capacity, but will generally be limited only by the capacity of the transformer which is supplying the current. Thus from 50 to 100 amperes may be drawn, depending somewhat on the nature of the load into which the rectifier is feeding current.

FIGS. 8 AND 9.—TWO VIEWS OF A RECTIFIER.

The machine may also be used as a self-exciting synchronous motor, developing from 1/10 to ⅛ h. p., according to the strength of field; and finally it may be driven by belt as a self-exciting alternator, supplying either an alternating current or a rectified direct current, or both, up to about 100 watts output.

Figs. 8 and 9 are reproduced from photographs illustrating a rectifier built from these designs.

## AMERICAN TELEPHONE PRACTICE.

### SELF-INDUCTION AND CAPACITY.

BY KEMPSTER B. MILLER.

Every insulated conductor is capable of receiving a certain charge when subjected to an electromotive force; for instance, if a metallic plate insulated from all surrounding bodies is connected to one terminal of a battery the other terminal of which is grounded, a certain amount of electricity will flow into the plate until its potential is raised to that of the battery terminal. The plate is then said to be charged, and the amount of electricity held by it determines its capacity. The charge of electricity on the plate will be considered positive or negative, according to whether the positive or negative terminal of the battery, or other charging source, was connected with it.

It is well known that no charge exists by itself—there is always an equal and opposite charge induced by it upon neighboring bodies. It is also well known that like charges repel each other, while unlike charges attract; that if an uncharged body be brought near a charged body an equal and opposite charge will be induced on the side of the uncharged body which is toward the charged body, and that similarly a charge on the same sign as that on the charged body will be induced on the opposite side of the uncharged body. If now the body which was originally uncharged is connected with the ground, this latter charge, that is, the one of the same sign as the original charge, will be driven to the ground, while the charge of opposite sign will still be attracted by the charge on the first body. The second body will therefore be charged, although it has not been in contact with the first. The action between charges of electricity taking place through an insulating medium is called electrostatic induction. It is found that where two conductors are placed side by side, but insulated from each other, the capacity of each will be greater than if the other were not present. For the purpose of holding charges in this manner the well-known Leyden jars have long been in use. They are usually made by coating a glass jar inside and out with a layer of tin-foil to within a few inches of the top. The outer coating is usually connected with the ground, while the inner coating is connected with a metallic rod approaching it through the mouth of the jar. If the innner coating is connected with a source of electromotive force, a current lasting but an instant will flow into the coating, producing a charge. This charge, which we will say is positive, will attract a nearly equal negative charge to the outer coating, repelling an equal positive charge to the earth, as already described. The amount of charge which the inner coating will receive under these circumstances is very much greater than if the outer coating were not present, and the capacity of the inner coating is therefore

Digitized by Google

much higher than before. A device, such as the Leyden jar, is called a condenser.

The capacity of a condenser is increased as the area of the conducting surface is increased; is increased as the distance between the conductors is diminished, and may be increased or diminished by using different kinds of insulating material between the conductors. The medium separating the conductors is called the dielectric and, as stated above, upon it depends to the greater extent the efficiency of a condenser. Several condensers built exactly alike so far as size of plates and the distance between them is concerned, and using different materials for dielectrics, will be found to have different capacities. This difference is due to a peculiar property possessed to different degrees by different dielectrics and called specific inductive capacity.

The specific inductive capacity of a dielectric is a measure of that quality which enables the dielectric to hold a charge between two conductors, as in a condenser. The specific inductive capacity of air is taken as a standard and is for convenience considered as unity; it is lower than that of any other known substance excepting, perhaps, hydrogen. If two condensers having plates of equal size and distance apart are constructed with dielectrics respectively of air and guttapercha, it will be found that the condenser having the dielectric of guttapercha will receive a charge nearly 2½ times as great as the condenser having the dielectric of air. The actual ration between the two is 2.462, and for this reasonu the specific inductive capacity of guttapercha is said to be 2.462. The following table gives the specific inductive capavities of some of the more important insulators:

| | |
|---|---|
| Air | 1.00 |
| Glass | 3.013 |
| Shellac | 2.74 |
| Sulphur | 2.580 |
| Guttapercha | 2.462 |
| Ebonite | 2.284 |
| India Rubber | 2.220 |
| Paraffin | 1.994 |
| Carbonic Acid | 1.00036 |
| Hydrogen | 0.99967 |

It is probable that very rapidly varying electro motive forces, such as are dealt with in telephones, the specific inductive capacities of the various substances would be higher in comparison with air than those indicated by this table.

Specific inductive capacity is a very important consideration in the construction of cables for telephone purposes. In the construction of these cables it is desirable, as will be shown later, to reduce the capacity of the wires of the cable to as great an extent as possible, and in order to do this the dielectric is, in the best forms of cables, made of dry air to as great an extent as possible. On the other hand, in the construction of condensers it is desired that the capacity may be as great as possible for a given area of plates and therefore some material other than air is used. Paper saturated with paraffin is perhaps the most commonly used, paraffin having about twice as great a specific inductive capacity as air, and moreover lends itself readily to the purposes of insulation. To sum up, the capacity of a condenser varies in direct proportion as the area of its plates, inversely as the square of the distance betwen the plates, and directly as the specific inductive capacity of the dielectric.

The effect of a condenser bridged across a circuit carrying an alternating current is to absorb a portion of the current as the electromotive force at its terminals increases, and as the electromotive force decreases, to give this current back to the line. Consider such a circuit when the electromotive force active in driving current through it begins to rise. Electromotive force at the condenser terminals will also rise, and current will therefore flow into the condenser. The strength of this current will depend directly upon the rate at which the potential at the terminals of the condenser is changing. When the electromotive force acting in the circuit reaches a maximum, the potential at the condenser terminals will also be a maximum and will for an instant cease to change. At this point the condenser is fully charged, but as the electromotive force of the line is not changing no more current flows into the condenser; in other words, the condenser current is zero. As the electromotive force in the line decreases, current will flow out of the condenser and into the line, because the condenser is not capable of holding so much charge at the lower potential. The flow of current out of the condenser reaches a maximum when the electromotive force in the line is changing most rapidly, and this occurs when it is passing through zero. From this it will be seen that the condenser current is zero when the electromotive force in the line is a maximum, and is a maximum when the electromotive force in the line is zero. This indicates, as in the case of self-induction, a phase difference of 90° or a quarter of a cycle. It is not so easy to say whether this phase difference is lagging or leading, but a consideration of the direction of flow of current throughout the cycle will throw some light upon the subject.

At the instant when the current flowing in the line (which is in exact phase with the active electromotive force in the line*), is positive and at a maximum, the condenser current will be zero. As the active electromotive force decreases toward zero the condenser surrent increases, but in a different direction—negative—because current is now flowing out of the condenser back to the line. As the active electromotive force reaches zero the condenser current is at its maximum negative value, and as the active electromotive force reaches its maximum negative value the condenser current reaches zero. During the next half cycle the condenser current increases to a positive maximum and decreases to zero, while the active electromotive force passes from a negative maximum to a positive maximum. In other words, while the active electromotive force and therefore the line current with which it is in phase decrease from a positive maximum value to a negative maximum value the condenser current is negative, and while the active electromotive force increases from its negative to its positive maximum value the condenser current is positive. The condenser current therefore reaches its zero value, while decreasing, 90° in advance of the same value of the active electromotive force; its maximum negative value, 90° in advance of the maximum negative value of the active electromotive force; and upon investigation it will be found that every value of the condenser current occurs 90° in advance of the corresponding value of the actual line current. The electromotive force which is in phase with the condenser current is called the condenser electromotive force and is 90° in advance of the electromotive force which is active in driving current through the line. This latter electromotive force, which, as we have said, is in phase with the current flowing in the line, is the resultant of the impressed electromotive force, and the condenser electromotive force, and therefore leads the impressed electromotive force by a certain angular distance.

The current equation for a circuit containing resistance and capacity is, as before,

$$\text{Current} = \frac{\text{Electromotive Force}}{\text{Impedance}}$$

In this case the impedance depends on the ohmic resistance of the circuit and on its capacity, and is equal to the following expression:

$$\sqrt{R^2 + \frac{1}{4\ ^2f^2c^2}}$$

Where f is the frequency, as before, R the ohmic resistance, and c the capacity of the condenser in farads. From this the current equation becomes

$$C = \frac{E}{\sqrt{R^2 + \frac{1}{4\pi\ ^2f^2c^2}}}$$

The denominator is the apparent resistance, depending upon the ohmic resistance of the circuit, the capacity and the frequency of alternations. An inspection of this equation will show that as the frequency f is increased the impedance or apparent resistance becomes smaller, and this acounts for the fact that a condenser will readily transmit rapidly fluctuating currents, such as voice currents. Evidently the effect of increasing f reduces the second member in the denominator of the equation, and if sufficiently great, this may be neglected, and the equation becomes simply

$$C = \frac{E}{R}$$

Again, increasing the capacity of the condenser also increases the effective current by reducing the impedance.

* The active electromotive force is the resultant of the impressed electromotive force and the condenser electromotive force, and is in phase with the current actually flowing in the line.

Digitized by Google

Every telephone line possesses electrostatic capacity, and may be considered in the light of a condenser. In the case of a grounded circuit the line wire takes the part of one plate of the condenser, while the ground and other neighboring conductors act as the other plate. In metallic circuits the one side of the line acts by electrostatic induction upon the other, and the two together, upon the ground and neighboring conductors. The capacity of a line, however, differs from that of a condenser in that it is distributed throughout the entire length of a line, while a condenser connected with a line would have all of its capacity at a single point. Capacity, such as that of a line, is termed distributed capacity in order to distinguish it from that possessed by a condenser, which may be termed local capacity. The effect of distributed capacity upon telephone currents may be more readily grasped by imagining a large number of condensers bridged across the two sides of a metallic circuit at frequent intervals. When the electromotive force impressed upon one end of the line increases, a current flows from the source over the line wire and into the condensers, charging them all according to the difference of potential across their terminals.

The difference of potential across the terminals of all the condensers will not be the same, because there is a certain drop, due to the ohmic resistance of the line wire. If the current flows in that direction long enough to charge all of the condensers on the line then a current will reach the distant end of the line, and if it continues in that direction, will attain its full value, in accordance with Ohm's law. It must be remembered, however, that each condenser is capable of taking a certain charge, and in order to receive this charge a certain quantity of electricity must flow over the line wire.

The quantity of electricity which flows through a circuit depends upon the strength of the current and upon the time it is allowed to flow. If the time is insufficient it will be impossible for enough current to flow through the circuit to charge the condensers up to the potential of the source, and therefore the current at the distant end of the line will not reach its maximum value, and in fact may not rise practically above zero. If, therefore, the electromotive force of the source is reversed before sufficient current has time to pass through the line to charge all of the condensers, the current will not reach its full value at the distant end of the line.

It may begin to build up in the opposite direction, and again be stopped on account of the insufficient time to reach its proper value in that direction. The time in which the current in such a circuit will reach a definite portion of its maximum value at the distant end of the line is called the time constant, and if the time represented by one alternation of the electromotive force is smaller than the time constant, the current will not reach that value at the distant end of the circuit, and the transmission will be correspondingly impaired.

The reduction in the actual volume of current transmitted by the effects of distributed capacity is, however, of less importance than the distortion of the wave form. The higher frequencies of current waves corresponding to the higher overtones are absorbed by the condensers far more readily than the lower frequencies, and therefore the waves corresponding to the higher over-tones are reduced to a much greater extent at the distant end of the line than those corresponding to the fundamental and the lower over-tones. This weeds out the upper harmonics, thus tending to destroy the clearness. Capacity, however, acts in still another way to alter the form of the wave. The angle of advance for the higher frequencies is greater than that for the lower, and therefore the waves of different frequencies are shifted with respect to their phase relation, thus greatly altering the wave form.

It has been shown that the electromotive force of self-induction lags 90° behind the active electromotive force, while the electromotive force due to capacity is 90° in advance of the active electromotive force. It is not difficult to conceive, therefore, that by properly proportioning the self-induction and capacity of a circuit the electromotive force of self-induction may be made to neutralize the electromotive force of capacity, and this result is readily obtained in experimental work.

In this case, even though self-induction and capacity may be present in a circuit to a large degree, the current flowing in the circuit is in exact phase with the impressed electromotive force, and its value is in strict accordance with the ordinary expression of Ohm's law. Unfortunately, however, for long-distance telephony such a balancing of self-induction against capacity can be obtained only for one particular frequency at a time. To thus tune a circuit for one particular frequency would render that circuit capable of transmitting efficiently one particular frequency of vibration, while the requirements of telephony are that all frequencies within the range of the human voice shall be transmitted with equal facility. Again, and unfortunately, it has been found impossible to neutralize distributed capacity with anything but distributed self-induction, and this has not yet been accomplished in practice.

As for trans-oceanic telephony, the high static capacity of the cable has so far proven an insurmountable obstacle. It is impossible to conceive a transmitter capable of forcing such rapid undulations through our present form of cables. Clearly then the solution lies in the betterment of cables, or the substitution of some other transmission medium, rather than the improvement of the instruments themselves.

There can be little doubt that trans-oceanic telephony will finally be accomplished, but the indications are that our knowledge at the present time is not sufficient to cope with the problem.

## STEAM AND WATER VALVES.

### CHECKS.

Probably James Watt needed a check valve so badly the first time he got up steam in a boiler that something in that line was invented off-hand upon the spot, a modification of a pump valve probably serving for the purpose until a more elaborate form of construction was designed.

Probably the ball form of check valve is one of the earliest forms of that fitting, but the cup valve was a standard form for many years until the swing valve was invented and perfected. Fig. 1

FIG. 1.—CUP VALVE.

shows a form of cup check valve as made by the Crane Company. The disc is attached to a stem, which plays up and down in the bonnet which forms a guide therefor. The stem, though turned cylindrical, is cast with four ribs at right angles to each other, as indicated in the engraving, whereby the passing fluid can flow to and from the bonnet cavity as the check rises and falls.

The disc seats squarely upon the metallic seat of the valve, and by unscrewing the bonnet both it and the valve disc may be lifted out for renewal or repair. Defacing the seat or disc of this valve must be cured by regrinding the seat, although a new disc can be slipped in in a minute or two.

Fig. 2 shows a valve in which it is unnecessary to replace the disc when worn. It is a Lunkenheimer valve and is made regrinding. The stem is a solid cylinder and the top thereof is slotted to receive a screwdriver, whereby the disc may be rotated and ground to a fit in the ordinary manner. This valve has a conical seat, but there is a sort of plunger underneath the disc which enters the opening in the seat, so that but little fluid can be forced past the seat until the disc has risen a considerable distance, thereby protecting it from the cutting action of dust and grit.

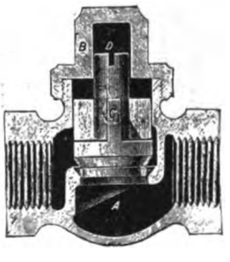

FIG. 2.—REGRINDING CHECK.

Digitized by Google

Considerable trouble has always been met with in check valve practice by the binding or sticking of the disc and its guiding stem. This is particularly the case when used with dirty water, the sediment catching between stem and bonnet, and in many cases preventing the closing of the valve, much to the annoyance of the engineer, and in some instances becoming a source of great danger.

A form of construction adopted by some valve manufacturers to obviate this difficulty is to use a ball-shaped disc. In fact, a ball made as nearly spherical as possible is the only loose part in this form of check, as shown in Figs. 3 and 4, the former illustrating a Lunkenheimer check valve, the latter a production of the Haydensville Manufacturing Com-

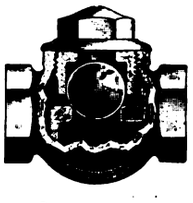

FIG. 3.—BALL CHECK.

pany. There is great similarity of construction between the two valves shown, and both are made for medium pressure, say 150 to 200 pounds to the square inch. It will be noted that there is a considerable difference in lift possible to the discs of the two valves shown. In all valves of this class the lift should be sufficient to give ample opening to the water passage, but it should be no greater than this. When either a ball or a disc check valve has excessive rise, there sometimes ensues such a hammering or pounding of the disc or ball upon the seat that both are quickly worn out. Some swing checks are ruined by this cause,

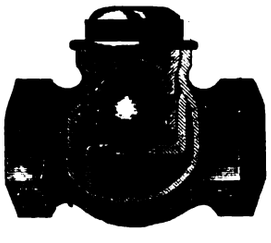

FIG. 4.—BALL CHECK.

and in certain cases where checks wear out very rapidly they may be made to last much longer by putting in a pin or a lug, which will lessen the rise of ball, disc or swing clack. But this must not be done to an extent which will reduce the flow of water through the valve, or increase the resistance to flow through the valve to any appreciable extent. If a change of this kind is contemplated, put an indicator in the pipe close to and in front of the valve, connect the instrument with the pump piston or plunger and take several cards. Then the same thing being done after limiting the rise of the valve, it is possible to ascertain if the flow has been interfered with.

In some check valves there is introduced a form of adjustable stop whereby any desired amount of lift may be given to the clack. Fig. 5 shows such a stop

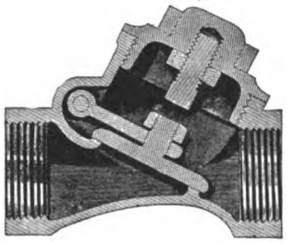

FIG. 5.—THE VAN WEIS SWING CHECK.

motion, which in this case consists of a set screw and lock-nut attached to the inner side of the bonnet. This valve is also made by the Haydensville Manufacturing Company, and is usually known as the "Van Weis" swing check. It will be noticed that the seat lies at a very flat angle with the axis of the valve, so much so that the use of this valve in a vertical line of pipe would not be satisfactory without the stop above alluded to, which prevents the swing or clack from falling back past the center of the pivot and

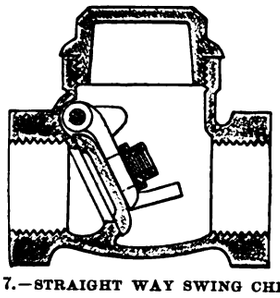

FIG. 7.—STRAIGHT WAY SWING CHECK.

thereby remaining open. Sand cannot very well find a lodgment in this valve, as the body of the valve curves up and inward at the bottom, thereby providing a form which causes the flow of water to wash the seat clean, instead of inducing a deposit, as might be the case if a hollow or a depression existed at that point.

Fig. 6 shows another form of check valve which has the same anti-sand collecting form at the bottom of the shell. There is no adjustable stop in this valve, but the shell is so designed that the clack strikes the upper portion of the valve body before it can get past the center. In

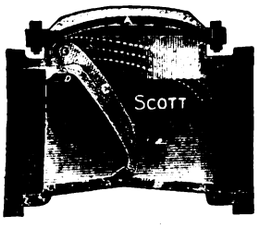

FIG. 6.—SCOTT CHECK.

this valve, which is made by the Roe Stephens Manufacturing Company, the swing makes a much greater angle with the axis of the valve than in Fig. 5. In fact, this valve is first-class for work in vertical pipes, as well as for horizontal use. The clack is made all in one piece, but in the larger sizes (above 14-inch) it is made in two pieces and there is a hole in the swing disc upon which another and a smaller swing clack is mounted, thus forming a duplex valve and obtaining a great area of opening with the least possible rise. In this form of valve the hinge of the clack is made to fit tightly in a recess in the body of the valve, so that no dirt can get in to bind and prevent the free movement of the swing.

Fig. 7 shows a form of straightway swing check valve wherein the clack stands at a still greater angle with the valve axis. The disc can swing up into a

FIG. 8.—STANDARD SWING CHECK.

recess, into which a plug is screwed instead of the usual bonnet. To prevent the swing from getting past the center when used on a vertical pipe lugs are cast upon the swing as depicted in the illustration.

This valve is a production of the Kennedy Valve Manufacturing Company and the disc is made in two pieces, the lower part being easily removeable for renewal or repair. In fact, the swinging gate revolves and is self-adjusting.

Still another check valve, and one in which the clack hangs at an even greater angle, is shown by Fig. 8. This the Crane Company calls its "Standard" swing

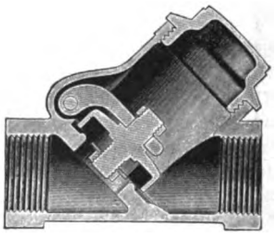

FIG. 9.—SELF-ADJUSTING SWING CHECK.

check, and it gives a straightway opening as large as the internal diameter of the pipe.

Fig. 9 shows a form of self-adjusting swing check made by the Jenkins Company, in which the regular Jenkins packing is used in connection with a loose connection between swing and disc.

There is ample room in the upper portion of the valve, which has a screwed in plug, instead of a bonnet. The clack has its motion limited, as it strikes against a side of the valve after it has risen sufficiently to give the required area of opening.

A peculiarity of this valve is that the seat is placed at an angle of 45 degrees,

Digitized by Google

thus making the valve exactly as efficient in either vertical or horizontal piping. The disc can be quickly and easily removed and a new one inserted in case of injury by sand or gravel. It will be noted by a close inspection of the engraving that the seat is counter-sunk a trifle —not enough to catch dirt, but enough to prevent sand and water from cutting, or rather enough to prevent their impinging upon the seat surface when flowing across it.

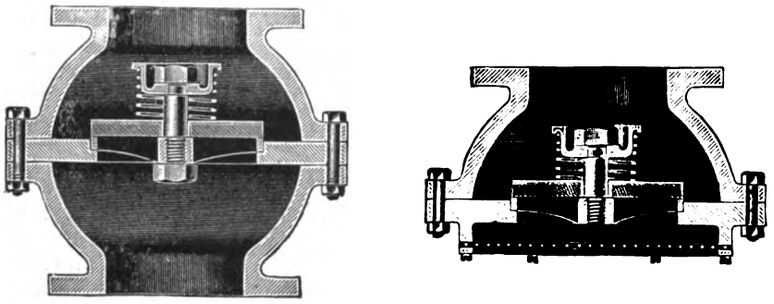

FIG. 10.—CHECK AND FOOT VALVE.

A peculiar form of check valve is frequently used at the bottom of a vertical pipe or line of piping. Then such a valve is called a foot valve, as illustrated in Fig. 10, which shows one of each kind. Really there is no difference in these valves as far as the seat and disc is concerned, both being exactly alike. In the foot valve the lower part of the body is cut off and a strainer screwed on. That is all the difference there is between them as made by the Kennedy Valve Manufacturing Company. In this class of valves the total area of valve opening should exceed that of the pipe by at least 10 per cent., and in the larger sizes the required area is obtained by placing a number of independent checks in the same case or casting. This should be done for sizes about 8 inches in diameter. The seats are removable, and are made in the form of spiders, with radial arms and a central hub, from which springs the arbor upon which the disc and spring are pivoted.

Quite a number of what may be called "freak checks" have been devised from time to time to meet certain engineering demands, and while some are valuable alone as freaks, others have proved their worth and in time will become standard articles. Fig. 11 shows a form of valve manufactured by L. Schutte and Company, in which there is a balanced horizontal check valve, in which the inclined suspension bar, shown projecting to the left directly under the stem, has a tendency to open the valve, while the bar at the right tends to keep the valve closed. The small counterweight acts when the valve is used. The stem and hand wheel is so arranged that the check may be used at will as a stop valve for fluids passing in one direction.

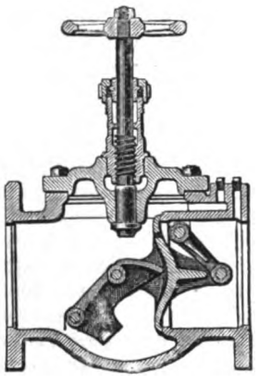

FIG. 11.—DUPLEX CHECK.

Another form of duplex valve is illustrated by Fig. 12, and is made by the Crosby Manufacturing Company. It consists of two checks contained in a single shell. The arrangement is such that if one of the swings should get out of order at any time the other valve in the shell can be thrown into service instantly by applying a wrench to a projection from one end of the shell and giving it a half-turn. This throws the defective swing out and the reserve one into line. At the same time it brings the injured swing under a hole closed with a screw plug, which may be removed at will, and the damaged check removed or repaired.

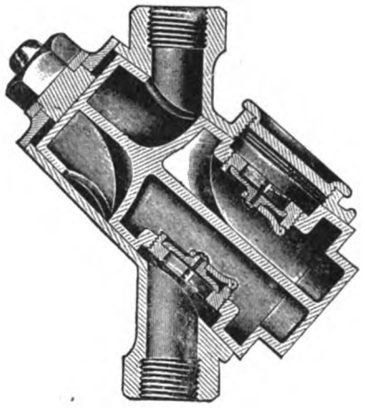

FIG. 12.—CHECK AND STOP.

If, instead of a half-turn, the shell be rotated only one-quarter of a revolution, both swing checks are put out of service and the fitting becomes a stop valve to all intents and purposes.

The trouble engineers meet with in using check valves usually consists in said valves sticking—sometimes open and at other times shut. A method of preventing the former trouble or, at least of overcoming it, has already been provided for in the valves illustrated above, and a valve with means for forcing the disc off its seat at any time is the subject of Fig. 13. Here the valve is

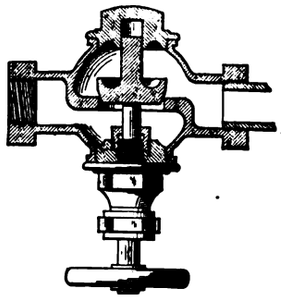

FIG. 13.—TINLEY'S CHECK.

of the disc and stem types shown at the beginning of this article. It is devised by James F. Tinley, and is particularly desirable for feeding several boilers in parallel from the same feed main. Then, if one of the checks stick, it may be quickly opened by means of the stem and hand-wheel shown in the engraving. A check nut in the bushing limits the vertical movement of the stem to a very small fraction of an inch, so at no time is the check held open thereby to any great extent.

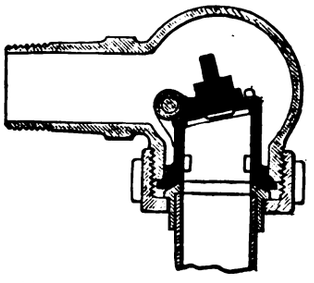

FIG. 14.—UNIVERSAL BOILER CHECK.

Another "freak" check, and one called by the manufacturers, H. Belfield & Co., a "Universal Boiler Check Valve," is shown by Fig. 14. This valve can be placed in any position, either vertical or horizontal and the seat and disc may be easily removed for repairs or cleaning. It is claimed by the makers of this valve that the usual wear of checks is due to a whirling motion given to the seat by the current of water, and by introducing means to prevent such motion the valves wear much longer.

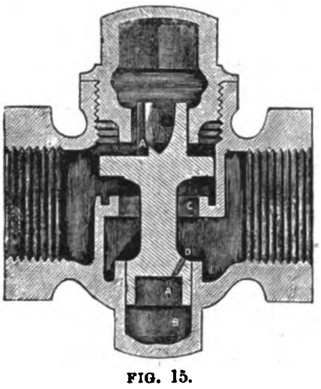

FIG. 15.

Digitized by Google

A form of noiseless water cushion check valve, as made by the Roe Stephens Manufacturing Company, is illustrated by Fig. 15. It is known as Florence's valve, and is made with a dash-pot and piston to work in same so as to form a cushion on water or fluid, with a small outlet to let the water in on the rising or lifting of valve, and to let a portion of the water out on the downward or drop motion of same, so that sufficient liquid remains in dash pot to form a cushion, so valve will not strike heavy on seat; the small opening prevents it from striking at top on lift of valve by the suction of water under piston in dash pot.

## INTERIOR WIRING.

BY CHARLES E. KNOX.

FEEDERS AND MAINS.

In this number the method of installing feeders and mains, known as "concealed work," will be considered.

The term "concealed," as here used, signifies that the wire or conductor is covered and protected in a conduit or pipe, and does not refer to the conduit itself, which may or may not be exposed to view.

The conductor and the conduit first require a brief consideration.

The wire used in this class of work should be insulated with the highest grade of rubber. "The best is none too good," and nowhere does this apply more truthfully and exactly than to rubber used for the covering of wires. It has become almost proverbial that the principal constituents of the rubber used on the majority of the different makes of wire, instead of being caoutchouc, are erstwhile rubber overshoes, rubber coats, etc., and to this list must now be added discarded bicycle tires. "Cast thy bread upon the waters; for thou shalt find it after many days." It may be that the very wire which carries the current for lighting your house is covered with rubber formed from the tires of your old '96 wheel and your last year's overshoes. Be assured that this is entirely within the range of possibility if the rubber on the wire is not carefully examined and tested. The insulation should, in my opinion, be placed on the wire in two layers, a thin inner layer or core and a thicker outer layer. Over this there should be a protective braid or tape covering. Braid has the advantage of being flexible, but it is somewhat bulky and absorbs moisture. Tape, on the other hand, is not bulky and does not absorb moisture to such a great extent, but it is apt to break when the wire is bent sharply. So much for the covering of the wire.

As to the wire itself, for feeders or mains the wire should be composed of strands of small wire twisted or formed into one conductor of the required size. Of course, where the feeder or main wire is smaller than No. 6 B. & S. gauge this absolutely essential, but for the larger conductors it is indispensable. For conductors larger than 300,000 circular mils, these strands should consist of very small conductors and should be twisted and united in a manner such as will give the greatest possible flexibility. The ease with which a conductor is pulled through a conduit greatly depends on the flexibility of the conductor.

The conduit should preferably consist of an iron or steel pipe having an insulating lining. The lining may consist of paper saturated with an insulating compound, which is the kind of lining in the conduit most used at the present time. Or it may consist of two or three coats of some enamel or paint baked on the inside of the tube. The former lined conduit has now been in use for several years and given fairly good satisfaction. The conduit with the enamel lining is a more recent innovation and is yet to be proven and tried. One thing is certain, however, and that is that a conduit with an enamel lining is far superior for the purpose of wiring to one having no lining. The last named has the advantage of enabling a conduit of smaller diameter to be used or a conduit of the same outside diameter with a thicker metal wall.

It is to be presumed that the route for the feeders and mains has been already laid out and the space allotted.

As the installation of the feeders and mains may be and generally is divided into two sections, viz., the horizontal portion and the vertical portion, we will consider them under these heads.

The Horizontal Portion.—This portion of the feeder conduits is generally confined to the cellar or first floor of the building and includes that portion of the feeders from the point where they originate (the switchboard) to their respective rising points. As the switchboard (or main cut-out, as the case may be) is generally located in the cellar, the conduits for the feeders are generally shown on the plans to be run exposed on the cellar ceiling or to be run under the floor above. Owing to the size or number of the feeder conduits, the space limitations, other pipes, ducts, etc., and for other reasons it is frequently necessary or desirable to modify or depart from the route or location shown on the plan.

As in the case of exposed wiring, the installation of the feeders should be started at the switchboard. When possible, each conduit should start directly above the switch with which that feeder connects.

Owing to the limited space between the beams and the floor above, it is generally necessary to run the feeder conduits on the cellar ceiling. When this is done the conduit must be firmly secured by hangers or clamps fastened to the beams overhead. These hangers should be placed not more than eight, or at the outside, ten feet apart and should be heavy and stiff enough to support the tubes without bending. These hangers may consist of channel (or T) iron or else of a frame formed of iron pipe. The former is the better and probably the cheaper method. The supports for the hangers may consist of beam clamps or rods passing through the flanges of the beam and pinned above the flange, or else of iron rods passing through the floor arches and secured to flat straps laid above the arches. In the case of a building of wooden construction the hangers could be secured to the wood beams with heavy "lag" or "wood" screws.

Where the head room is sufficient the feeders may be run in two or more tiers.

When there is sufficient space between the beams and the flooring of the floor above the cellar, it is usually better to place the feeder conduits under the floor above. This obviates the necessity of hangers and usually results in a considerable saving in materials and labor. Where the flooring is of wood, however, care should be taken to leave space at intervals for the sleepers, in order that a good fastening for the rough wood floor may be obtained. Where the floor is of concrete, the conduits should be strapped down firmly to the beams or arches, so as to afford a firm and inelastic bed for the concrete.

Vertical Portion of Feeders.—It is presumed that special chaces or spaces have been provided for the rising portion of the feeder conduits. These conduits should be supported by clamps or brackets at least every twelve or fifteen feet.

A good support for the conduit is obtained by clamping the conduit at each floor to the beam, if there be a beam in or at the rising space; if there be no beam the clamp may fasten in the wall or else rest on a pair of iron bars placed across the chace. This clamp is frequently placed under the coupling on the conduit, which prevents any tendency of slipping. In some instances where the vertical portion of the feeders is direct and where there are no bends or offsets, it is necessary to support or fasten the conductors themselves as well as the conduits. Where the vertical portion is direct and over 75 feet, this precaution should always be taken. This, of course, may only be done by interrupting the conduit and placing a clamp with an insulating bushing around the conductor, the clamp resting on the end of the conduit. Of course this is for some reasons objectionable, and in many cases it may be obviated by clamping the conductor at the upper and lower ends. In some instances, however, the weight of the conductor and the consequent strain is so great as to require supporting at intermediate points. The argument that the conductor sags until it assumes a sinuous form and that the grip thus obtained between the conductor and the conduit is sufficient to prevent the conductor from slipping, does not hold good in the light of experience. I have known a conductor to fall through a tube so fast, even after the horizontal portion had been run (there being a junction box between the horizontal and vertical portions), that it entirely settled that question in my mind forever.

One point not yet mentioned, which is

Digitized by Google

equally important in both the horizontal and vertical portions, is the necessity of avoiding steam pipes. Wherever possible a space of at least two inches should be left between steam pipes and the conduits. The insulating compound with which the paper (used for insulating the standard conduit) is saturated, begins to soften at about 150° F. High temperatures are also injurious to the rubber covering of the wire.

Owing to the difficulty involved in pulling large conductors through a run of conduit in which there are more than four elbows or bends, it behooves the contractor to avoid, if possible, having more than four elbows in any of the "runs." Where it is impossible to avoid this and where the runs are long, a junction box should be placed in "the circuit" somewhere where convenient. The feeder wires may then be pulled from their point of origin to the junction and then from the box to their respective terminating points. A good place for the location of the junction or "pull" box is at the juncture of the vertical and horizontal portions of the feeders.

It is sometimes possible to reduce the number of elbows in a "run" of conduit by making offsets or bends to replace the standard elbows, furnished by the conduit manufacturer. It is a very difficult matter, however to bend large sizes of conduits without flattening the pipe or cracking the lining. It takes good workmen to do this properly, and even they will have trouble with it occasionally, owing to soft or thin spots in the pipe. Where it is absolutely essential, however, to make a bend or off-set at the building, the pipe should be slowly heated, and a core of wire or other flexible material should be placed inside the conduit to prevent it from collapsing. The conduit should then be bent so as to form a gradual curve instead of a series of angles, which is the usual result.

## Letters on Practical Subjects

### Wire Gage Numbering.

*To the Editor of American Electrician:*

Why not use all that is good in the Brown & Sharpe system. If there is anything on earth more "fearfully and wonderfully made" than wire gage numbers, I have not found it.

In the Brown and Sharpe system we have arrived, geometrically, at a series of diameters which are shown on the chart in thousandths of an inch; a system so perfect that it has been almost universally adopted in this country. Not content with the completion of a good thing, we have turned a somersault and tried to get back into the old rut of Birmingham numbers. Instead of numbering as the chart naturally suggests, the order has been reversed and the wire having the greatest number of mils is given the lowest serial number, until the old limit of No. 1 is passed and the absurdity is fittingly ended by representing the largest size on the list as $4 \times 0 =$? This, or Nos. 1, 20 or 40, expresses nothing as to the diameter or area of the wire and we must go to the tables to ascertain what a number means.

Why not take from the chart the numbers as well as the diameters and make the number of a wire correspond with the number of mils it has in diameter? If No. 40 was changed to No. 3 we would know at a glance that it had three mils diameter and nine circular mils area. Similarly, change No. 20 to No. 32, from which its area 1024 is quickly found.

There may be reasons in some cases for drawing wires to fractions of a thousandth, but for most purposes those drawn to even thousandths will fully meet needs. Practically this is done now; few wires that I use are drawn accurately to the fractions of mils as given in the tables. I have in hand now pieces taken from my stock, from the best makers; No. 18 gages exactly 40 mils, the tables say 40.303. No. 23 gages a small fraction over twenty-two mils, the tables say 22.571; No. 30 gages exactly ten mils, the tables say 10.025; No. 36 gages five mils, as it should.

F.

### Wireless Telegraphy.

*To the Editor of American Electrician:*

Sir:—Having read a number of articles on wireless telegraphy, I thought the following would be of interest to some of the readers of your columns in regard to the theory of action of the coherer.

The so-called coherer is a small glass tube, in the ends of which are terminals enclosing in the space between them small particles of conducting material.

The simple principle of action of the lightning arrester, which is designed to protect outdoor electrical circuits, is sufficient to drive away any mystery connected with the coherer.

A lightning arrester is connected between both sides of the circuit, and when the induced electrostatic charge is sufficient in quantity it will break through the resistance between the air-gaps and follow the path to earth.

But what happens when this discharge between the air-gaps takes place? The discharge spark produces a path of metallic vapor through the air space, and it being a conducting path, the current from generator will make a short circuit over this conducting path and will continue if means are not provided for breaking this conducting path of vapor.

This same principle is applicable to the coherer. When the oscillatory discharges pass through the coherer there will naturally be a spark between the particles of the conducting material, and of course each spark will be a conducting path for the current of the battery connected thereto, and thereby greatly reduce its resistance. Means must be provided for breaking this conducting path between each particle, which is accomplished by hammering on the tube of coherer and causing the particles to change their relative positions, breaking each path of vapor.

Apparently the same result could be obtained by using a magnetic blow-out instead of hammer.

Some authorities claim that its action is produced by the waves falling directly on it, and also that it must have a certain definite position, which to me is apparently absurd.

S. P. Thompson's text book on Elec. and Mag. says that the line of oscillation of the oscillatory wave should be parallel to the line of the oscillation of the receiver; the receiver being the wings and the conductor connecting them, in which is placed the coherer.

The electrical surgings in the receiver are caused by the waves falling on the entire conducting length of the receiver from one wing to the other.

It is then obvious that it matters not in what position the coherer is placed, only so that the conducting part of the receiver external to the coherer is in the line of the induced oscillation.

In a lecture before the Royal Institution of London, the author stated the following: "Another apparent anomaly was that Marconi's relay acts even when placed in a metallic box."

From the above arguments it is obvious that the coherer may be screened ever so much from the waves and yet act.

The author also stated that it has been suggested that we have in the measurement of the variable resistance of this instrument (coherer) a means of determining the intensity of the energy falling upon it. This suggestion is also apparently impossible.

Not having the apparatus to experimentally verify the above arguments, I will leave them for criticism.

EDW. J. FRIMAN.

Hanover, Pa.

### A Mild Puzzle.

*To the Editor of American Electrician:*

My attention was directed to Mr. J. C. Brown's "mild puzzle" in your February number, by the reply in your March issue of Mr. R. L. Johnston, of Bangor, Me., who makes the novel proposition, that impressed and counter e.m.f.'s, are uni-directional and additive.

As Mr. Johnston's reasoning is palpably incorrect, I beg to present the following as the solution, viz.: That the pressure on the mains was either 115 volts, instead of 110, from the inception of the test, or, provided Mr. Brown actually measured the voltage at commencement, that an increase in potential was effected, and existed when the voltmeter at lamp terminals showed 115 volts; in other words, the voltmeter at lamp terminals simply measured the difference in pressure between the mains from which the lamp

Digitized by Google

was in reality being fed. In substantiation of the foregoing, I desire to present the following reasons:

The dynamo must either generate a pressure in series with that of the line, or in opposition to it; the former fulfilling "booster" conditions; the latter "motor," if the e.m.f. generated is below that of the line, "generator" if above.

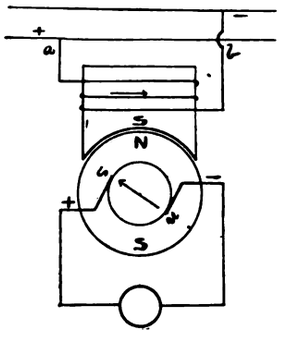

FIG. 1.

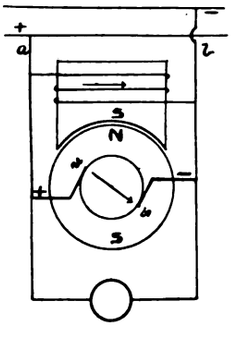

FIG. 2.

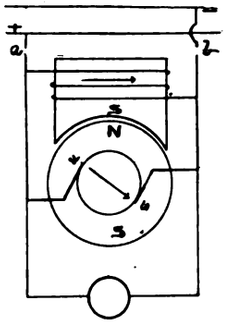

FIG. 3.

If the "booster" condition existed, a short circuit would result, between the negative bus-bar of generator at power station, and the positive brush of "booster," the extent of the short circuit depending on the resistance of the return; the "motor" condition is hereafter described, and the "generator" is untenable with increased speed manifestation.

In Fig. 1 let the main tapped by "a" be positive, and that by "b" negative. The field having a right-handed winding a south pole will be created in the pole-piece shown; assume the armature is wound left-handedly, then with a right-handed rotation (as viewed from commutator end) in this right-handed field, the left-hand brush will be positive, with a pressure of 100 volts existing between it and negative, and the armature will be magnetized as shown in the figure, the block letters denoting polarity induced by fields, and the smaller letters the poles created by armature current, resulting in field demagnetization, the arrows indicating direction of current in field-winding and armature.

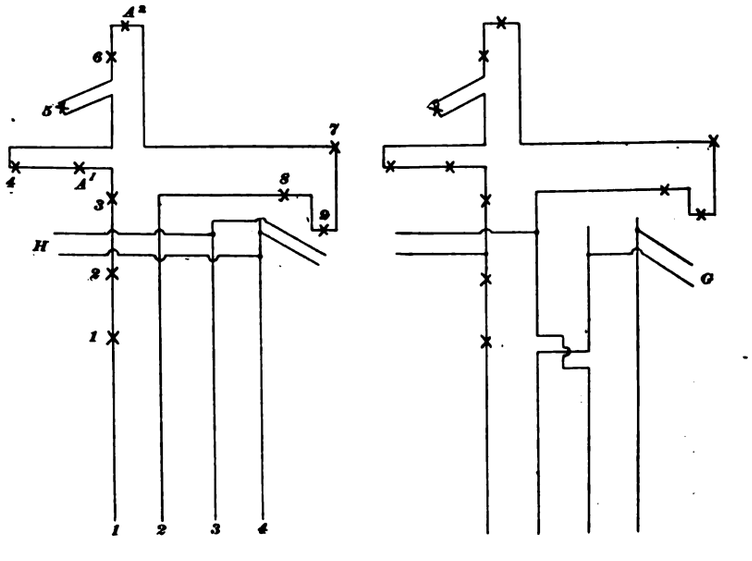
In Fig. 2 when the mains are thrown on the brushes, the impressed e.m.f. exceeds the generated e.m.f. and sends a current through the armature in the same direction as the effective pressure, and in a reverse direction to that shown in Fig. 1. We now have a motor with a lead at brushes instead of a trail, and the armature current consequently has a magnetizing instead of demagnetizing effect on the fields, assisting in the production of a more powerful rotation; the quondam generator speeds up and drags the armature of the driving motor ahead with it.

A little consideration will show that as the counter e.m.f. of armature approaches the value of the impressed e.m.f. the machine in nearing the "generator" stage, when the driving motor would be again called upon to exercise its function. So soon as it exceeds the impressed voltage the dynamo again generates, excites its field, supplies lamp and voltmeter, as well as feeding to the circuit, and the armature conditions are again as represented in Fig. 1, the speed consequently dropping to its former value, an effect which did not occur.

Again, if the voltmeter registered the generated pressure of dynamo, when the connections "a" "b" were broken as in Fig. 3, the machine would continue to run as a shunt-wound generator, precluding the last effect observed by Mr. Brown.

Breaking the connections "a" "b" with the machine still acting as a motor, the currents circulating as in Fig. 2, the induced currents in field and armature (shown by arrows in Fig. 3) each tend to neutralize the other, destroying the field, or nearly so, the armature being left practically short-circuited with field winding, voltmeter and lamp, the voltmeter as a result registering zero.

I believe from the above considerations that the voltmeter simply indicates the pressure on the mains.



R. C. Harris.

## The Crossing of an Arc and Alternating Circuit.

Some interesting and puzzling phenomena, caused by the mistakes so frequently made by outside wiremen of interchanging arc and alternating lines, are reported by Mr. W. H. Coleman, superintendent and treasurer of the Andover Electric Company, Andover, Mass. The circuits are shown in the accompanying drawing, the left-hand sketch showing the proper arrangement, and the right hand the lines as some telephone wiremen who rearranged them got them twisted.

The results are best described in Mr. Coleman's own words, as follows:

"On the arc circuit there were 10 No. 12 T. H. lamps, three 25 c.p. 13.22-volt 6.8 ampere incandescents between the station and where the cross connections were made, and within a distance of a mile were those marked on the figure. Beyond this there were four arc and five more incandescent lamps. Those nearest station and beyond the crossed district burned all right. Within the section the result was as follows: Incandescents 1 and 2 no noticeable change; the lights on the transformer H would burn all right for a short time and then seem to follow the action of regulator on arc machine. From transformer G the lights were about half candle power all the time, with no change up or down. Arc lamp $A^1$ was not up to candle power, but steady; arc $A^2$ burned all right. Incandescents 3 to 9 were most of the time very bright.

THE CROSSING OF AN ARC AND ALTERNATING CIRCUIT.

The voltage on alternating line 1000, and that on arc 2250. The alter ing machine was a 100 kw. General E tric, and the arc an L. D. 12 G. E. machines worked all right, and no ble was experienced on any other se of line. I found the voltage on secor of transformer H from 109 to 100, down to 94, on transformer G from 1 41—time run from 6:30 P. M. to 1 No trouble from transformers or n since the date of cross connection, 25, 1898. Should like to hear the op of your readers on the above mixtu

*304. What is an ohm-meter?*

This is an instrument sometimes used for measuring resistance where it is desirable to test with a high voltage, but where none is available except as supplied by the testing outfit. It consists of two parts, a small hand dynamo capable of generating 100 volts or more, and the instrument proper. The latter has two coils at right angles to each other, and a magnetic needle, which takes a position between the two coils according to the relative currents in the coils. One coil is

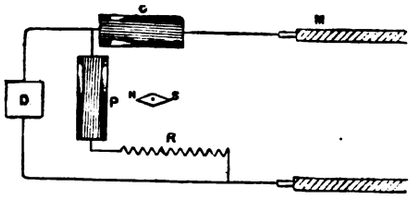

DIAGRAM OF AN OHM-METER.

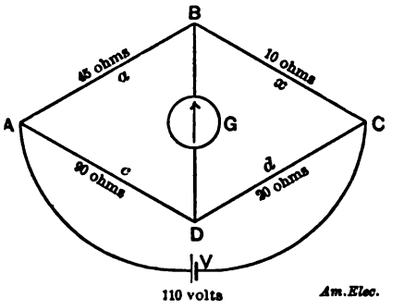
connected between the dynamo and one terminal of the circuit whose resistance is to be measured; the other coil is connected in series with a high resistance inside the instrument so as to form a shunt across the main circuit, as shown in the figure. When the dynamo is operated, the current divides, part going through the coil *C*, and then through the main circuit whose resistance is to be measured, while the remainder goes through the coil *P*, and the high resistance *R*. The currents through the two coils are inversely proportional to the resistances in their circuits, since the same voltage is applied to both, and therefore they attract the needle correspondingly. For a given voltage of the dynamo, the attraction of coil *P* is constant, while the attraction of coil *C* becomes greater as the resistance in the main line becomes less. The pointer attached to the needle will therefore move toward *C* as the resistance in the line becomes less, and the scale may be divided to indicate the resistance in the main circuit.

*305. For what range of resistance is the ohm-meter suitable?*

It will measure resistances from about five meg-ohms (5,000,000 ohms) down to about 1,000 ohms. It is convenient for measuring the insulation resistance of wiring in houses that are not yet connected with the supply circuit.

*306. What is a Wheatstone bridge?*



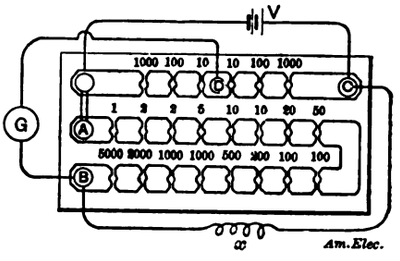
The Wheatstone bridge is an arrangement of resistances with a battery and galvanometer for measuring resistances. It usually consists of two "proportional arms", of such values that one arm has one, ten, one hundred or one thousand times the resistance of the other arm. The third arm is divided into tenths, units, tens, hundreds and thousands of ohms. The resistance to be measured becomes the fourth arm. When the bridge is balanced, the unknown resistance has the same ratio to that of the divided arm as one of the proportional arms is to the other.

*307. What is the theory of the bridge?*

Suppose we have two conductors connected in multiple, and having a battery or other source of current applied to their terminals. The potential would fall from one end to the other in each wire, and for any point in one wire, a corresponding point in the other can be found at which the potential has fallen the same amount. If a galvanometer is connected between these two points, no current will flow since there is no difference of potential between its terminals. We have a close analogy in the case of a river which divides and flows around an island; the water at every point along a line across the river at the head of the island is at the same level; also every point in another line across the river at the lower end of the island is at the same level; if the water flows along the two sides of the island without any sudden falls, for any point on one side of the island, we may find a corresponding point on the other side which has the same level; between these two points no current would flow if a canal were dug between the two. In the Wheatstone bridge the galvanometer circuit corresponds to the canal across the island, and when no current flows through the galvanometer it shows that the two ends of the circuit have the same potential. If then we know that one end of the canal is one-tenth of the total fall from the upper to the lower level, we are sure that the other end is at a corresponding point.

*308. Give an example illustrating the principle of the bridge.*

To better fix ideas, we will take electric



THE CIRCUITS OF A WHEATSTONE BRIDGE.

light currents and voltage, as indicated in sketch. By Ohm's law, $C = \frac{E}{R}$, the current in *A B D* is $110 \div 55 = 2$ amperes; in *A e D*, $110 \div 110 = 1$ ampere. The drop ($E = C\ R$) from *A* to *B* is $2 \times 45 = 90$ volts; from *A* to *C*, $1 \times 90 = 90$ volts. Therefore, the drops to *B* and *C* being the same, the potentials at those points will be equal, and no current will flow through the galvanometer, *G*. That is, when $a \times d = c \times x$, the bridge is balanced. This may be expressed,

$$x = \frac{d}{c} \times a.$$

In practice, the resistances of the two wires, *c* and *d*, are fixed in a certain ratio for a given measurement (in this case, 20:90, but usually as 10:100 or a multiple of 10), and the value of *a* varied until a balance is obtained. A commercial Wheatstone bridge is shown herewith, with the parts lettered to correspond to the above, *x* being the resistance under measurement. In this case, *c* is the left part of the upper row, *d* the right part, and the two lower rows correspond to *a*. If *c* were plugged for 1000, and *d* for 10, and if 1425 plugged in *b* brought a bal-

A WHEATSTONE BRIDGE.

ance, then the value of *x* would be 14.25 ohms.

*309. Is it safe to use a bridge on a 110-volt circuit?*

Not ordinarily. The example given was simply to explain the theory. In practice, only two or four volts are commonly used, although in measuring high resistances, it is sometimes desirable to use higher voltages. The current should be kept on only a very short time, in order to avoid heating the bridge and so changing its resistances.

*310. What range of resistances can be measured conveniently with a bridge?*

It depends largely upon the bridge and the galvanometer. The best bridges will measure from 0.000001 to 111,000,000 ohms. Ordinary portable bridges will measure from 0.01 to 1,100,000 ohms with fair accuracy.

*311. Are bridges suitable for testing the resistances of armatures of large dynamos?*

They are not usually considered accurate for such purposes, since the resistance when running is apt to be different from that when standing still; such resistances should always be measured when the machine is hot and carrying current, and for such work an ammeter and a low reading voltmeter are more reliable.

*312. Is a bridge suitable for testing insulation resistance?*

Not if the insulation is to be used for high potentials. The reasons for this are two: insulation for high potentials should be tested not so much for ohmic resistance as for its ability to stand the high potentials; again, the resistance with a low potential may be quite different from that with a high potential, on account of the electrostatic attraction between different parts bringing them closer together.

*313. How should insulation be tested for high potentials?*

In testing apparatus at the factories, it is common to subject all parts supposed to be insulated, to a difference of potential several times that which they are to stand in use.

# Queries and Answers

How can the ring for the ammeter described in the October, 1898, number of the American Electrician be permanently magnetized without winding wire upon it

C. O.

By bringing the metal of the ring into contact with the north pole of a dynamo and rubbing the latter around to one pole of the ring and then pulling it off, following this by bringing the middle of the ring into contact with the other pole of the dynamo and rubbing it around to the other pole of the ring; the two processes being alternately repeated the ring can be fairly well magnetized.

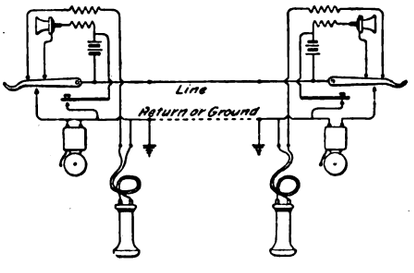
Three plates of a 12 ampere hour chloride accumulator loose capacity. Negative plates show no white deposit, but become a general blackish color with a slight deposit of black powder over affected parts. The rubber bands used to bind the plates together are dyed a rusty red at the four corners and this dyeing is only noticeable in the cells affected. The electrolyte is made from chemically pure acid diluted with water supplied from a lime rock district. Can find no cause for the defect and the other cells in battery are in good condition. What is the trouble and remedy? A. M.

The plates should be removed from the electrolyte and carefully scrubbed in clear water, using some cheap form of hand scrubbing brush. Care should be taken not to spread the negative plates of the elements too far apart, as they may be broken from the connecting strap, but if the work is done carefully the deposit referred to can be removed. It is possible that the difficulty was caused by the water, and either rain water or distilled water should be used in its place.

What current from a 110-volt circuit will be required to heat a quart of water from 70 to 210 degs. in five minutes? What should be the size of the wire? A. L. S.

Taking the weight at 2 lbs., 2 (210—70) = 280 heat units will be required, which are equivalent to $280 \times 778 = 217{,}840$ foot-pounds. Dividing by 33,000 gives 6.6 h.p.-minutes, or 1.32 h.p. for five minutes. Since there are 746 watts in a h.p., we have 984.7 watts, or 9 amperes at 110 volts. Allowing for heat losses, probably 12 amperes would be required. The resistance will be $110 \div 12 = 9.2$ ohms. The gage of the wire will depend upon the temperature it will stand. No. 22 iron wire will probably do.

What is a direct-current transformer? A. D. H.



A machine for transforming a direct-current voltage—called usually a dynamotor or motor-generator. It may consist of one armature with two windings and two commutators, or two identical machines direct-connected, one running as a motor and the other as a generator, the motor voltage being different from the generator voltage.

What is the difference between cycle, period, frequency and alternations? A. R. B.

Cycle and period are synonymous. The frequency is the number of cycles or periods per second, and an alternation is half a period. A cycle refers to the time required by an alternating current to rise from zero to, say positive maximum, fall to a negative maximum and return to zero.

How can the battery of a microphone and induction coil circuit be used for ringing a bell or buzzer at the other end of the line? W. E. C.

This can only be accomplished when the line is short, so that the low voltage battery used in microphones will deliver sufficient current to ring an ordinary bell. The instruments should be wired according to the accompanying diagram, which is self-explanatory.

Will I infringe any patent rights if I make and sell the field of a dynamo similar to that used on Wood arc machines? Also, what are the disadvantages of this field? R. G. P.

No. The broad patent rights on all but a few peculiar types of field magnets have expired. The advantage of the Wood arc type is the support of the shaft in the yoke of the magnet without special pedestals. The disadvantage is the necessity of taking down the field magnet to remove the armature.

I desire to run three dynamos in parallel, two of the same size and one larger, for incandescent lighting. Should I use the rheostats now in use to keep any one machine from taking more than its share of the load or will I need some other arrangement for the purpose? H. S. C.

Yes. The same rheostats will apply.

Can you advise me of a table of the current carrying capacity of iron wire when used as a resistance in sizes from No. 4-0 to No. 8? J. C.

Round iron wire in such large sizes is rarely used and probably no table of its carrying capacity has ever been published. In an article by Mr. P. M. Heldt in the "American Electrician," March, 1897, the carrying capacities of sizes down to No. 8 were given. The capacity of larger sizes can be readily estimated from the following considerations. The cross-section of wire doubles for every three numbers in the Brown & Sharpe gage, while the surface area per unit length doubles for every six numbers. For example: No. 5 wire has twice the cross-section of No. 8 and No. 2 has twice the cross-section of No. 5 and twice the surface area of No. 8. To obtain a uniform dissipation of energy per unit surface area the carrying capacity may be assumed to double for every 4 numbers in the gage, thus No. 4 wire would have twice the carrying capacity of No. 8, which is given by Mr. Heldt as 17 amperes in a wooden frame and 20 amperes in an iron frame.

Can you tell me if 1 h. p. delivered by a steam engine makes 746 watts? I have a two phase generator of 2200 volts and 68 amperes. How can I tell what horse power it will take to run it up to 68 amperes? W. J. L.

Theoretically 1 h. p. indicated upon the steam engine should give 746 watts, but practically there are many losses, so that only about 400 to 600 watts are obtainable. Small, inefficient machines give the lower figure, and very large generating sets the higher one. The dynamo will require theoretically 400 h. p. when giving 68 amperes on each phase, practically about 450 h. p. will be needed.

Is it advisable to have the ground wire of an alternating machine in the same ground with that of an arc machine, and is an iron bolt driven in rock or stone a good ground? H. F. W.

There is no objection to having the ground wires of any number of circuits connected to the same ground if the latter makes a good connection, but the ground which you describe certainly does not do so. In a stony or rock formation a good ground can be obtained by going down to the level of permanent dampness and laying there a considerable surface of metal, such as old steel rails, sheet copper, old piping or similar second-hand material. This should be carefully connected by soldered joints to the wire from the switchboard, all such joints underground being painted to prevent their corroding.

I have built a small series dynamo with an ordinary cast-iron shuttle armature. The machine works all right when excited by batteries, but otherwise it gives a small current and refuses to build up. What are the troubles? E. K. M.

Very small machines with solid iron armatures, unless they have a very narrow air gap and run at a high speed, are only with difficulty made to build up at all. It would be well to try higher speeds and more turns of wire in the series field. It is more than likely that so much series field would be required that there would be little energy left for the external load.

What is the formula for calculating reactance between wires of the same alternating current circuit and for getting the drop and potential in all lines? D. U. S.

The method of calculating the drop in alternating current lines having self-induction was described in the "American Electrician" of June, 1897, by Ralph D. Mershon.

What is the usual per cent. loss in watts in transforming a current? D. U. S.

Very large transformers of several hundred kilowatts have efficiencies at full load running up to 98½ per cent., i. e., they lose only 1½ per cent. of the power transformed. Small transformers of 20 light and 40 light, etc., lose from 5 to 10 per cent. at full load and a greater percentage at lower loads. In ordinary house to house service where only a few lamps are on during a short time in the evening while a transformer is wasting energy all day long, the average efficiency falls as low as 60, 50, or in extreme cases 40 per cent.

## CARBONS.

FOR ARC LIGHTING, BATTERIES, TELEPHONES, BRUSHES, ELECTROLYTIC AND OTHER PURPOSES; HOW AND WHERE THEY ARE MADE.

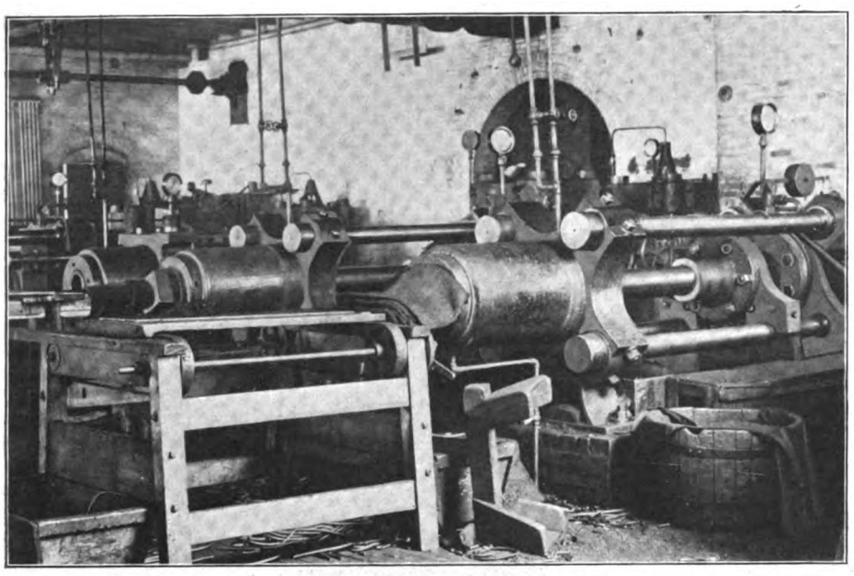
Carbon, in some form, is usually a prominent factor or element in every machine or appliance employed for the production or use of electric energy. The human eye seems to be so designed that it is co-related to the light rays given off in the burning of carbon, so that this substance, in some form, has been employed by men for light in all the ages, from the pine knot and animal fat in primitive times to the latest developments of modern lamps, whether oil, gas or electric light. To tell how it is refined and fitted especially for electric service is the mission of this article. The facts which form the basis of the story were ascertained on a trip to Cleveland, where a visit was paid to the works of the National Carbon Company, which are located near the western limits of the city.

These works are of special interest, being, it is claimed, the best equipped and most extensive works devoted to this industry in existence. The buildings are of brick, seventeen in number, arranged in parallel lines, and cover twenty-three acres, in which about eight hundred men are employed. The products are not by any means confined to lighting carbons, but embrace a great variety of chemical battery elements, as well as complete primary batteries for all purposes; also telephone transmitter parts, including back plates, diaphragms and their companion granules or carbon shot; also carbon motor and generator brushes, lightning arresters, rods and strips of various sections, including those of large diameter employed as smelting electrodes and for electrolytic purposes.

THE AUTOMATIC PLATING MACHINES.

To write the full history of the material from which the ordinary lighting and battery carbons are produced, it would be necessary to visit the Pennsylvania petroleum wells, and ask of nature the secret of its production and then follow it to the tide-water refineries, for the material is known as coke and is a by-product of the process of oil refining, being the solid product or residuum that remains in the stills of the refineries after the oils have been evaporated. This is delivered to the carbon works by the car-load and comes in irregular chunks or bodies of black porous material, somewhat lighter than coal-coke. This material is stored in great quantities in a long pile thirty feet high in the receiving department, which occupies one end of a long building, the other end being occupied by the calcining retorts and cooling floors.

It is first ground in a vertical bark mill to what is known as pea-size, and from this, by means of belt elevators, it is stored in large iron tanks above the retorts. From these it is drawn into small iron cars which run along on top of the retorts and discharge their contents directly into the calcining ovens, where it is subjected to a high temperature by the burning of gas, which is manufactured from coal on the premises. The ovens are kept closed so that the material burns in its own gas, by which process all the volatile matter and other impurities are consumed, leaving the charge virtually as pure carbon. In the process of calcining, the gas is turned on or off by degrees, and, after cooling to a certain degree, the material is hauled out through doors in front and falls into a metal trough running along in front of the retort, in which is a link belt conveyor, by means of which it is delivered to a point near the middle of the building, where it is again elevated, and by means of a conveyor directed along above a long iron floor, to which it falls through flexible chutes, which, by being properly manipulated, deliver it in an even layer over the floor, where it is left to cool.



From this floor it drops to a conveyor, which delivers it to an adjoining building, where it is again elevated and delivered to the grinding mills, of which there are a number, both vertical and horizontal, the latter of which are similar to the burr stone mills employed in grinding grain. From these, by suitable conveyors, the powdered material is delivered to a set of bolting machines by which it is separated into different grades, the coarser grades being returned and reground, as is also all scrap from imperfect carbons. Following the bolting process, the material is delivered to the mixing room, where are a number of iron barrels or boxes, which revolve like the rattlers used in foundries. These are heated by steam and in this process the binding material is incorporated with the carbon powder.

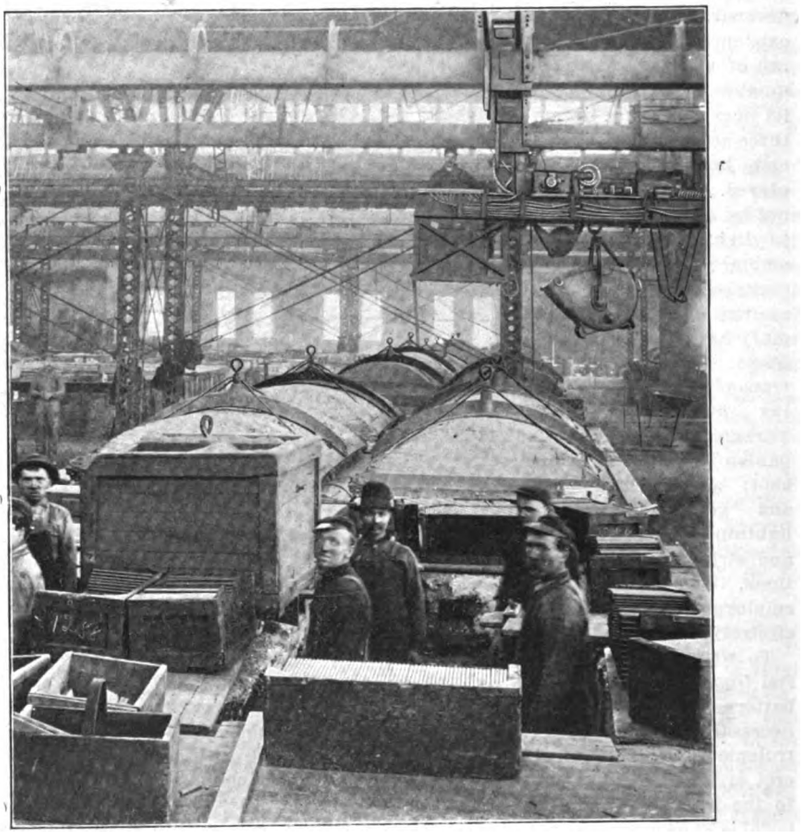
The binding material is a product which has also been prepared by a special process and which has been ground and bolted in about the same manner as is the carbon. Being suitably mixed, the material is conveyed to a cooling department, where it is made ready for the molding or forcing process.

In the making of the lighting pencils two processes are followed; one is known as the molding process and the other the forcing. In the former the material is carefully weighed and then placed in the molds, which consist of grooved plates of steel containing from twelve to eighteen forms, depending upon the diameter of the pencils to be molded. An attendant carefully packs and adjust the material, then smooths it off with a straight-edge, but there is no excess of material, so accurate is the weighing process. The molds being in two parts, the second or upper part is now placed upon the powder and pressed down with the hand, when it is ready for the press. The molders occupy little booths with tables on each side of a pair of endless chain conveyors which run in opposite directions, and upon these the molders place the filled molds, which are then conveyed in the direction of the hydraulic presses. Before reaching the latter they are led over a slow-running conveyor which passes through a furnace heated by gas, and when they emerge they are placed by an attendant upon the head of the verti-

Digitized by Google

cal plungers of the presses, of which there are two, one on each side of the line of conveyors. A second attendant manipulates the valves, when the two parts

THE JUMBO FORCING PRESSES.



of the mold are pressed together with great force and then released, when the attendant removes the mold and its contents from the press and places it upon the return conveyor, by which it is taken back and removed by each molder as his mold comes in position.

The molds are returned still hot, and each molder, after removing the formed pencils, which are held together by a thin web of material, places them upon a corrugated pan, on which they are held straight until cool, and by which they are removed and conveyed to the stripping room. To refill the molds the attendant first gives them a coating of oil and then weighs out the material as before described. There are a number of molders employed to each pair of the chain conveyors, and there are several pair of conveyors. In the stripping room the pencils are broken apart by hand and deftly fed one at a time into the strippers, which automatically draw them through very rapidly and shave off the portions of the web that may adhere to the sides of the pencils. At this work some of the hands become very expert, being able to break apart and feed into the machine more than a hundred pencils a minute. From this department the pencils go to the baking furnaces.

We will now follow the material as it is formed by the forcing process; and, in this department, we find a number of presses which are large horizontal machines called Jumbo presses, having cylinders of large diameter in which plungers are fitted and by which the material is forced through dies in the outer end of the cylinder. Before it is placed in the presses the material is formed into compact cylinders by hydraulic pressure; then these billets are fed one after the other into the cylinders of the press. The size of the rod or form depends upon the die; and, for making the lighting pencils, the material is forced out into grooved trays and broken off in lengths of about four feet, in which they are left for a time to cool, after which they are cut up into various lengths by being placed in a frame with suitable adjusting and cutting appliances. The same process is followed in forming the large rods employed for electrolytic purposes. Some of these are three inches or more in diameter.

The baking process follows and all types of carbons are subject to about the same degree of heat. The baking furnaces occupy one of the largest buildings, covering perhaps six acres, which is provided with three large brick smoke-stacks that provide a draft for the entire lot of furnaces. These furnaces are constructed of fire-brick and are provided with a removable arched roof; the roof being composed of fire-brick, but held in shape by means of bars of channel iron, and so designed that they can be removed and shifted about from one furnace to another by means of overhead traveling electric cranes. The furnaces are filled with the pencils, which are carefully piled in regular rows with a thin covering of carbonizing material between the layers; and, when filled, the surface is covered with a kind of clay which vitrifies in the process of baking and covers the bed with a scale so that the gas which is employed as fuel does not come in contact with the carbon. The process of baking requires eight to ten days, and the fuel gas is manufactured on the premises. After being allowed to cool, the top of the oven is removed, when the pencils are lifted out by means of forks, not unlike hay-forks.

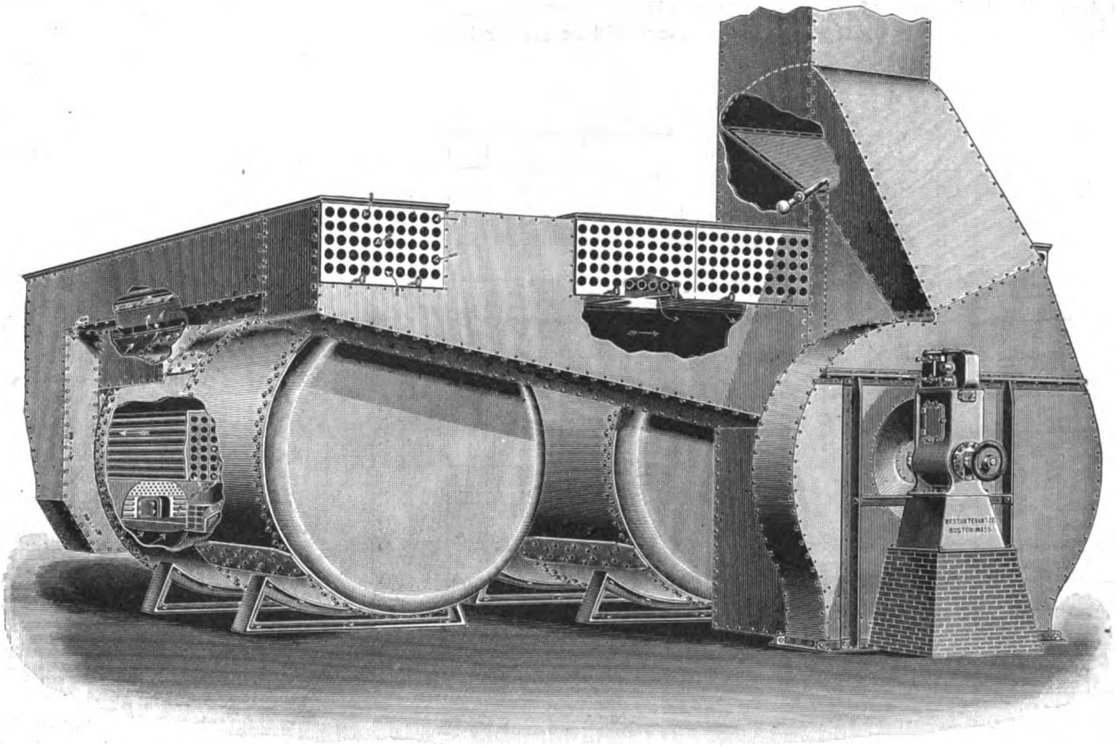
Being placed on suitable racks, the carbons are next delivered to the inspecting and sorting rooms, where they are carefully sorted and tested for straightness. For this purpose they are allowed to roll down the incline surface of a steel plate in such a position that the attendant is able to detect any crookedness in the pencil by means of the light rays that can be

THE BAKING FURNACES, WITH CRANE FOR SHIFTING FURNACE LIDS.

Digitized by Google

seen between the plate and pencil. From thirty to forty hands are employed in this work. They are usually sorted into three grades, known as No. 1, No. 2 and culls; only the No. 1's, however, are employed for long pencils, the others being cut up into short lengths designed for use as the lower carbon of a lamp, being usually about seven inches in length, while the ordinary length of the long pencil is twelve inches, and in some cases fourteen. The culls and seconds usually provide enough of the shorter lengths, so that only the long pencils are molded or forced. Such pencils as have been formed by the forcing process have now to be pointed, and this is done by machines especially constructed and said to be recent inventions, for which patents have been applied for. In the same department are machines for accurately planing motor and generator brushes, in which a number of brushes are clamped in position and are moved along against the face of an emery wheel. In the same department are the machines for filling the cored carbons. The material for this purpose is a secret preparation, and is much like a thick metallic paint, and is ground and mixed in a special designed machine, when it is forced into the cavity of the carbon under great pressure on a hydraulic machine, in which the pencils are placed one at a time and filled about as fast as the attendant can put them in and take them out.

Such pencils and brushes as require to be copper plated are taken to the plating departments, of which there are two, one for the brushes, in which the plating is done in the ordinary manner by suspending the blocks in the electrolytic solution, where they remain until thoroughly plated. Formerly the lighting pencils were plated in the same manner, but more recently new machines, entirely automatic, have been installed. From this process the carbons are delivered to a traveling conveyor which connects with the packing room.



The testing department, which is one of the most important in the production of perfect carbon, occupies a large room on the second floor of one of the principal buildings, and here are provided a number of arc lamps of different types, in which samples of pencils from each furnace are tested for life and efficiency, there being suitable ray testing lenses for determining the light-giving rays.

In order to complete the story of the manufacture of the battery and telephone elements, it will be necessary to return to the molding department, and here we find a large number of hydraulic presses of curious design and various shaped molds in which the great variety of designs are formed, the material in all cases being carefully weighed and packed in the molds, when either a screw or hydraulic pressure is applied. In such batteries as have the cover and cup of carbon, the threads by which the two parts are screwed together are formed in the process of molding. Telephone diaphragms are molded in very thin sheets and cut out in round forms in the process. These various forms, including the battery and telephone parts, are then baked or fired in about the same manner as described for the pencils.

## THE UTILIZATION OF THE WASTE HEAT OF THE FLUE GASES FROM A STEAM BOILER.

No greater waste occurs in modern steam boiler practice than that which is inherent in the employment of a chimney for the production of draft, namely, the loss of heat in the escaping gases. As the chimney depends for its action upon the maintenance of a temperature difference between the internal gases and the external air, it is manifest that with a chimney this waste can never be eliminated. It may be palliated, it is true, by the building of higher chimneys, so that the same intensity of draft may be obtained with a lower stack temperature. But such means of providing for the utilization of the otherwise waste heat are expensive. For instance, if, with an external temperature of 60 degrees and an internal temperature of 500 degrees, sufficient intensity of draft is produced by a chimney 100 ft. high, it will require a height of 175 ft. to produce the same draft when the temperature of the gases is reduced to 250 degrees. In addition, the means provided for extracting this heat will increase the resistance, and provision for overcoming the same will have to be made by a still greater chimney height.

The heat losses incident to the operation of the chimney and the discharge of the flue gases at high temperature are so great as to always warrant a careful investigation as to the possibilities of their reduction. Heretofore the feed water

INDUCED-DRAFT PLANT ON ELLIS & EAVES SYSTEM, WITH STURTEVANT FAN, AT AMERICAN LINE PIER, NEW YORK.

Digitized by Google

economizer has been the best known appliance for this purpose, but its utility is necessarily limited. It shows the greatest gain when the normal temperature of the flue gases is high, or when the fuel cost is excessive. The lower the temperature of the flue gases the less the opportunity for saving, and naturally the less the cost of fuel per ton, the less will be the financial saving due to a certain percentage reduction in the quantity of fuel required to produce a given result. In other words, the fixed charges and operating expense upon an economizer may approach so closely to the saving resulting from its use, that its introduction becomes questionable.

To a large extent, the limitations of the efficiency of an economizer have been set by the chimney itself, because of its inability to produce the necessary draft when the gases are sufficiently cooled to show a gain in economy. Any device which can produce the required draft without the waste incident to the operation of the chimney, must of necessity present claims for consideration.

The fan stands as the most prominent factor in the production of artificial draft, and its prime claim for utility in connection with the abstraction of heat from the gases lies in its high efficiency as compared with a chimney. The chimney operates to move the air simply by displacement, due to the difference in density, while the fan acts mechanically to cause the same movement.

Under the ordinary conditions of boiler draft, the fan requires only about 1/75th part of the power, as measured in heat expenditure, that is necessary for the production of the same results by means of a chimney. In other words, the fan renders available for utilization practically all of the heat of the flue gases, and the opportunity is presented for cooling them down to the lowest practicable temperature.

The waste which occurs in ordinary practice is sometimes startling. Messrs. Donkin & Kennedy found in 17 independent boiler tests that the heat lost up the stack when no economizer was used, ranged all the way from 9.4 per cent. to 31.8 per cent. of the total heat of combustion.

The theoretical losses incident to the burning of coal having a heat value of 11,720 B. T. U., with 100 per cent. excess of air, are shown by the accompanying curve. Had the heat value been higher the temperature range greater, or the excess of air over 100 per cent., this amount of course would be greatly increased. At a temperature of 800 degrees, with ordinary commercial coal, and an excess of air of 150 per cent., the waste would amount to about 40 per cent.

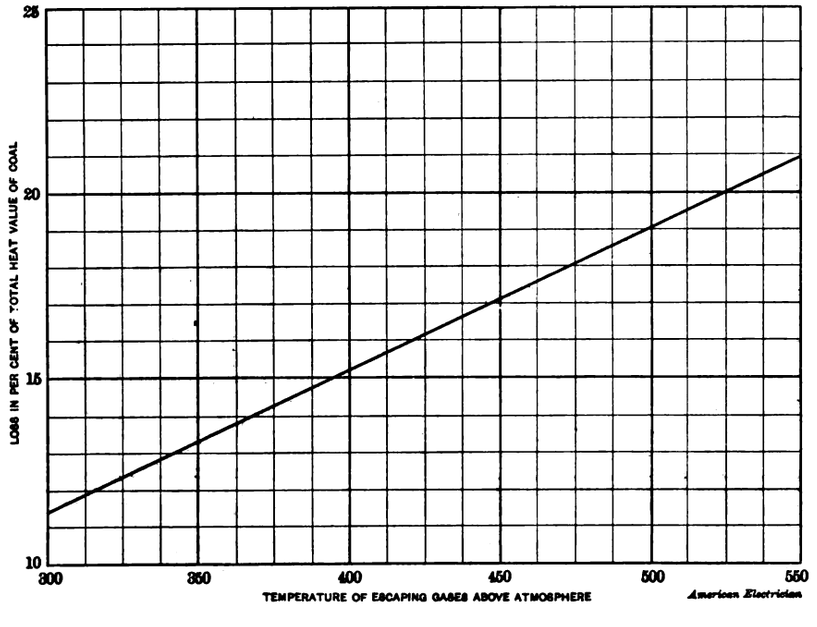


DIAGRAM SHOWING LOSS IN FLUE GASES AT DIFFERENT TEMPERATURES.

With the feed water economizer installed in connection with a mechanical draft apparatus, Roney has shown results of which the averages for nine different plants are given in the following table:

| | Degrees. |
|---|---|
| Temp. of gases entering economizer.... | 526.3 |
| Temp. of gases leaving economizer..... | 269.6 |
| Decrease in temperature of gases..... | 256.7 |
| Temp. of water entering economizer.... | 150.4 |
| Temp. of water leaving economizer..... | 297.1 |
| Increase of temperature of water,..... | 146.7 |
| Fuel saving in per cent..... | 14.64 |

Another means of utilizing the waste heat is coming into prominence in the form of the air heater or heat abstractor. The purpose of this device is to cool the flue gases and co-incidently to heat the air supplied to the furnaces. The limit of heat abstraction is, under these conditions, purely commercial in its character, that is to say, the gases should not be cooled below a temperature which will fail to show a financial gain when the fixed charges of the heat abstracting device are taken into account. In 1881 and 1882 were conducted the notable tests of J. C. Hoadley upon a special form of heat abstractor. All of the factors concerned were very carefully studied. It was primarily determined that a blower was necessary to produce the draft when the gases were reduced to minimum temperature. The results of tests showed a reduction to 162 degrees as the gases escaped to the chimney, the cooling of the gases through 213 deg., and a warming of the air through 300 deg. The heat lost in the gases was thereby reduced to about 5 per cent. of the total heat of the fuel, and about one per cent. of the steam was required for operating the blower. Since then many devices have been introduced for this purpose.

In marine practice the Howden system has assumed prominence. In this device the gases pass through tubes placed in the uptake connections, while the air is by means of a fan forced across these tubes, and thence through a false front to the boiler furnaces. Tests on board the S. S. St. Louis showed a temperature in the funnel of 564 deg. and a resulting temperature in the air reservoirs of 263 deg. This device, as ordinarily introduced, is not particularly adapted for stationary work, although it may be specially arranged for this purpose.

Another form of heat abstractor illustrated herewith is the Ellis & Eaves. This apparatus, shown here as applied to two marine boilers, consists of a series of tubes placed above the boilers. Through these tubes the air is drawn to the ash pits, whence it passes through the fire, the combustion chamber, the boiler tubes and the uptake, and thence around the heating tubes on its way to the fan. The fan operates on the induced principle, the gases passing through it, all objectionable action upon their part being avoided by water cooling the inner journal of the engine.

The particular apparatus located at the American Line Pier, New York City, here illustrated, has shown a temperature of 456 deg. at the fan outlet, and 315 deg. at the air downtake while burning 41.26 lbs. of coal per sq. ft. of grate per hour.

Of course with this type of boiler the normal temperature of the gases is high, but there appears to be an opportunity for further development of an apparatus of this character which may be applied to any ordinary boiler, and will coincidentally decrease the temperature of the flue gases, increase the temperature of the air supplied, and facilitate combustion because of the higher temperature of the air admitted.

A device like this is adaptable under practically all conditions, but very evidently requires a fan for the production of draft because of the great resistances introduced by the abstracting device.

## THE PERFORMANCE OF WAGNER SINGLE PHASE MOTORS.

An interesting series of tests has been carried out by students of the University of Nebraska, under the direction of Prof. R. B. Owens, with a 5 h. p. single phase motor, such as was described in the last issue of the American Electrician, built by the Wagner Electric Manufacturing Company of St. Louis, Mo. From the results of these tests the following information has been gleaned.

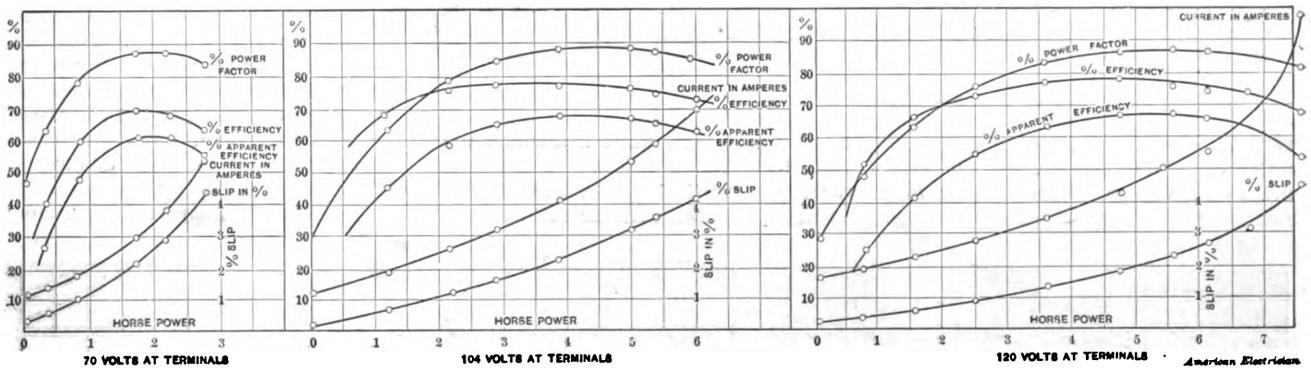
The motor was run with a Prony brake to determine its output and was supplied through a Weston wattmeter to determine its input in energy, and a Siemens dynamometer and Weston voltmeter to determine its apparent input, and hence its power factor. The speed was measured by an indicator consisting of a small magneto generator and voltmeter, and the slip was determined by means of contacts on the motor and generator and a bell circuit connected through both in such a way as to audibly indicate the number of revolutions lost per minute. The curves of efficiency, power factor, slip, etc., with different loads were determined for 70, 80, 90, 100, 104, 110 and 120 volts; three of these, viz., those at 70, 104 and 120 volts, being reproduced herewith to give an idea of the effect of voltage variations on induction motors.

It will be noted in general that the load which the motor will carry increases with the voltage, the slip, for example, being 4 per cent. with a load of only 2½ h. p. at 70 volts, a load of 6 h. p. at the normal voltage, and a load of over 7 h. p. at the highest voltage. The efficiency at normal voltage rises to 78 per cent., the same value being reached at the higher voltage, but only at a higher load, which might be expected from the increased iron losses with the increased density of high voltage. The maximum efficiency at the low voltage is only 70 per cent.

The power factor reaches almost exactly the same maximum value, about 88 per cent., at all voltages, but, as might be expected, this maximum is reached at higher loads on the higher voltages, owing to the fact that they require a greater magnetizing current and therefore a greater energy current must be introduced to bring up the power factor.

In general it is obvious that the machine will operate satisfactorily over a range of pressure from 100 to 125 volts, as wide as that allowable in direct current shunt motors. The iron losses were measured at different voltages with the rotor standing still and the brushes removed, so that there could be no currents through its windings. They showed for 104 volts a value of 200 watts, or about 5½ per cent. of the rated output of the machine. It should be noted, however, that the iron losses would be likely to be less with the motor running, owing to the fact that the frequency of alternations impressed upon the rotor in that case would be comparatively small. Unfortunately the starting torque, the current required therefor and its power factor were not recorded with the motor in its starting condition, viz., with the armature running on the repulsion principle. The report states, however, that "the motor is tble to pull up from standstill more than 50 per cent. overload with no excessive increase over full load current."

An interesting property brought out by the tests was the fact that the efficiency of the motor when hot reached a higher value for practically all loads than when cold, the difference amounting to some 2 to 3 per cent. This was perforce ascribed to reduced iron losses in the hot condition, as the copper losses must necessarily be higher and friction, windage, etc., the same.



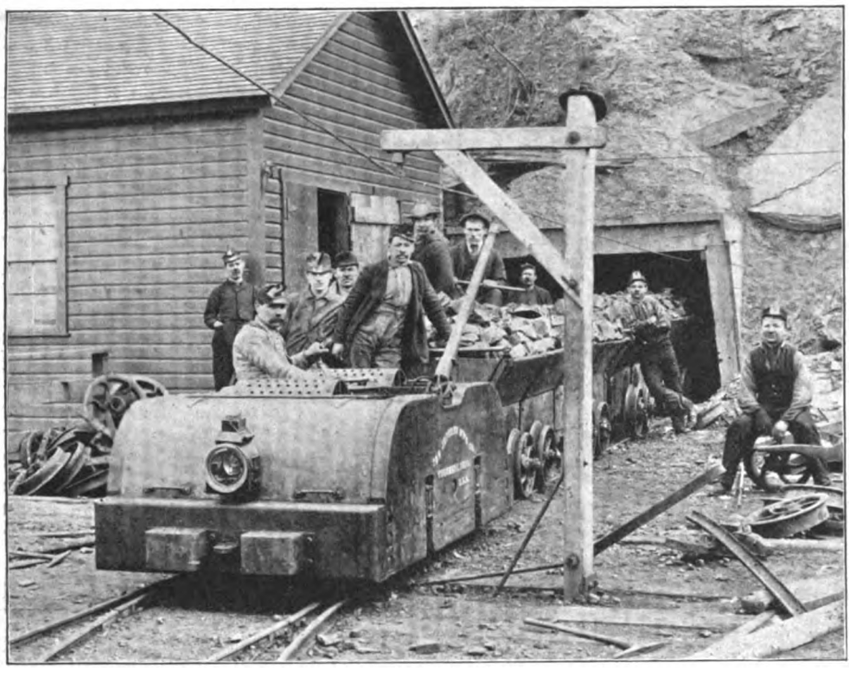
Tests were also made to determine under different conditions the distribution of the flux over the air gap of the machine. This was accomplished by means of test coils wound on different portions of the stator and determinations of the instantaneous e. m. f.'s generated in them by means of an adjustable contact on the generator and the usual battery compensation and telephone indicator. The tests showed a remarkably true rotating field with the rotor running light, there being no discernible difference between the magnetic strength at different angular positions.

While the tests, owing to difficulties which arose, were not completely worked out to determine the distribution under loads, they indicate an elliptical distribution of the magnetism, not differing seriously from a true circular rotary field.

## THE USE OF ELECTRICITY IN THE MINING AND HANDLING OF BITUMINOUS COAL.

History shows that in 1828 the first coal was mined and offered for sale as fuel in the State of Ohio. But great difficulty was experienced in supplanting wood as a fuel by coal, owing to the great abundance of the former, and it took twenty years to get coal used to any extent for house heating or steam purposes. A similar difficulty has been experienced in supplanting the old methods of mining by modern electrical machinery, but now this new power is finding a welcome in this field, both by the operators and miners, and is already in use in bituminous mines in Pennsylvania and Ohio to a greater extent than is generally supposed.

The credit for the introduction and use of electrical appliances in coal mining is largely due to the efforts of the Jeffrey Manufacturing Company of Columbus, Ohio, which is an extensive manufacturer not only of electrical coal cutting and handling appliances, but also of elevating and conveying machinery for all purposes.

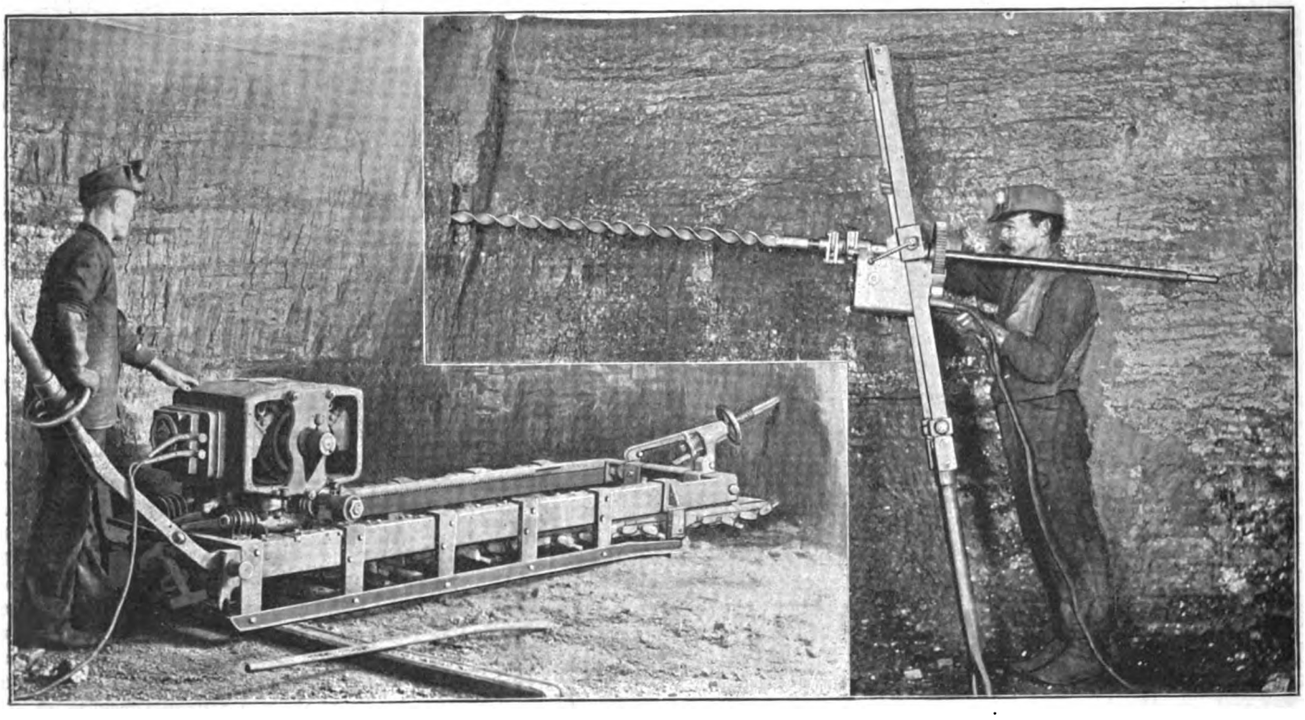


CURVES SHOWING THE ACTION OF A SINGLE PHASE INDUCTION MOTOR AT SEVERAL VOLTAGES.

The most interesting of these appliances are the cutting machines, which make an undercut at the base of the vein, when the drilling is done near the top, so that the face readily breaks down by the use of explosives. The under cutting machines are made in two types, known as 17A and 16A, being distinguished by the motors employed. The former is made for use in thick veins of coal, or in veins from thirty inches in thickness up, and the latter in veins down to twenty inches. The same motor operates the cutter, and propels the machine along the track, when necessary to move from one chamber to another. These machines are shown in one of the accompanying figures and consist of a low steel frame work, with guides and with a shifting platform which carries the motor and the cutting tools. These consist of an endless chain or belt that travels around the edge of the platform, being held in position by guides, and which carries at short intervals chiseled cutting points or knives, set alternately at an opposite flaring angle. The frame being in position with the working end towards the face of the vein. it

Digitized by Google

is anchored and braced by means of dogs and jacks against the roof, when the chain is set in motion by power from the motor, and the platform is gradually moved forward by a rack and pinion, forcing the cutter chain into the face of the vein, and so making an undercut about four inches high, and with the large machine seven feet deep and forty-four inches wide. The time required for such a cut is about five minutes, when the platform is withdrawn and the position changed.



A machine of this description replaces about twenty miners, as the output of coal per miner by the old method, when the vein is reasonably deep, is from four to six tons a day, while a machine will mine from 100 to 150 tons in the same time. The vertical cuts are made with a similar machine, only the cutting chain is placed in a vertical position and cuts a channel up and down in the face of the vein. There is also a third type of machine, known as the long wall type, on which the cutters are inserted in a circular disc or cutting wheel, and which is designed to work in a circular chamber, and cuts a continuous channel all around the face of the vein.

A MINE LOCOMOTIVE.

The drills are operated by means of a small motor, mounted on a standard, or an extension rod, which is supported in a vertical position between the roof and floor of the chamber, and by means of gearing drives a thimble through which the drill is forced as it revolves, and which can be adjusted to any angle.

The electric locomotives are made in different sizes, weighing from two to fifteen tons. These are designed to give a draw bar pull of from 500 to 6000 pounds, and to haul a number of loaded cars, depending upon the grade, equal on the level to a gross load of 180 tons. The frame work of the locomotives is made of cast beams, and the largest machines are about thirty-nine inches in height, and of any gauge from 17½ inches to standard. The wheels are about 28 in. in diameter, with standard journal boxes and running gear. The power is transmitted to the axles by a single reduction gear, in about the same manner as in street railway practice. In some cases the operator is located at the front end, and in others at the middle. The brakes are of the automatically locking screw type, and the controllers of the cylindrical type, with series parallel attachment, and are worked by a lever, with the resistance arranged in steps, to give uniform acceleration in starting a load. The trolley wire is supported from the roof by malleable iron barbed split bolts, which are readily adjusted, and the insulation is of a water-proof pattern, with an air space and a hood to shed water.

## WATER WHEELS FOR HIGH PRESSURES.

It is not the purpose of this article to follow the evolution of the turbine and the still more modern jet wheel, from the crude paddle wheel of our ancestors, but rather to illustrate and describe the types of wheels which are now common in the public eye and especially those made by James Leffel and Company, Springfield, Ohio, with notes as to where and how they are made. This firm has been engaged in the manufacture of turbine wheels for thirty-eight years and is still in the forefront of manufacturers of this class of wheels, both as to quantity and perfection of design, as is shown by its Niagara type of wheel. The works are located in the suburbs of Springfield and include a number of large brick buildings conveniently arranged along the lines of two steam railways. The main machine shop is a building 340 feet by 60 feet, and is equipped with heavy iron working tools of almost every description, for it should be remembered that the company provides the complete equipment of a power plant, including the wheels, penstocks, shafting, gears and rope transmission pulleys, and ordinarily employs about 150 hands.

The output embraces three types of the Leffel horizontal and vertical turbine, known as the Standard, Special and Samson, beside the jet type, better known as the cascade or impact wheel, which is especially designed for heads from forty to 2000 feet and upwards, these types embracing over 160 different styles and modifications. Besides the wheels the output includes the Leffel type of engines and stationary and portable boilers.

Fig. 1 illustrates the case and gates of a 56-in. Samson turbine, in which it will be noted that the gates, which are balanced, are placed in the periphery of the case and are made of either bronze or steel, depending upon the service for which they are designed. The gate operating mechanism is also shown, the power being supplied to the small shaft, each individual gate being moved by a rod connecting with a thimble which surrounds the main shaft. In Fig. 2 is shown the design of the runner, or wheel proper, which is mounted within the case. The curves and shape of the buckets or flukes are so designed as to give the greatest economy, having reached 85 per cent. of efficiency at seven-eighths gate.

FIGS. 1 AND 2.—THE CASE AND RUNNER OF A SAMSON TURBINE.

# New Apparatus and Appliances

### JENNEY UNIVERSAL MOTORS.

The accompanying cuts illustrate the new type of motor recently perfected and placed on the market by the Jenney Electric Manufacturing Company, Indianapolis, Ind. On account of the construction of this motor the company has styled it the "Universal" type. Fig. 1 illustrates the motor mounted in the usual manner, with the supporting base on the under side, and with standard pulley on armature shaft. Fig. 2. illustrates the motor bolted to side of post, and with back gear.

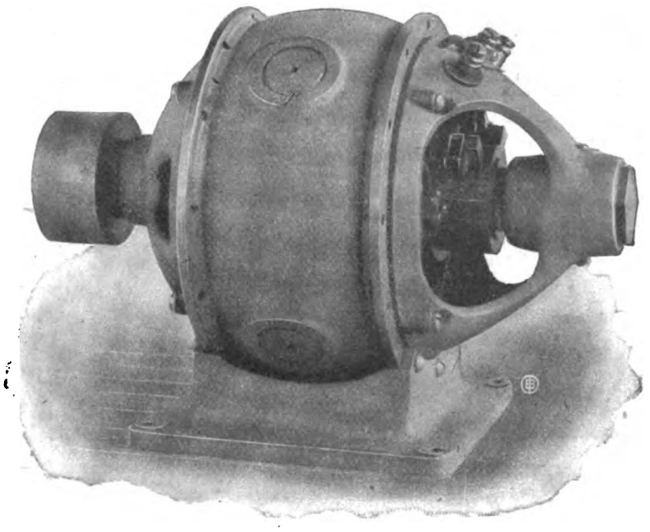

FIG. 1.—BELTED MOTOR UPRIGHT ON BASE.

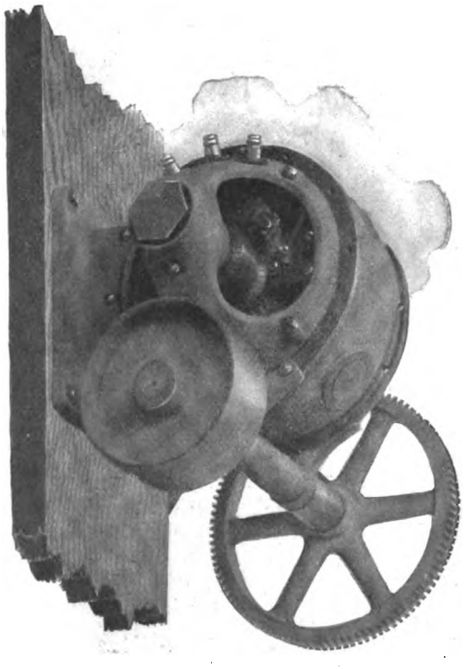

FIG. 2.—GEARED MOTOR WITH BASE IN VERTICAL POSITION.

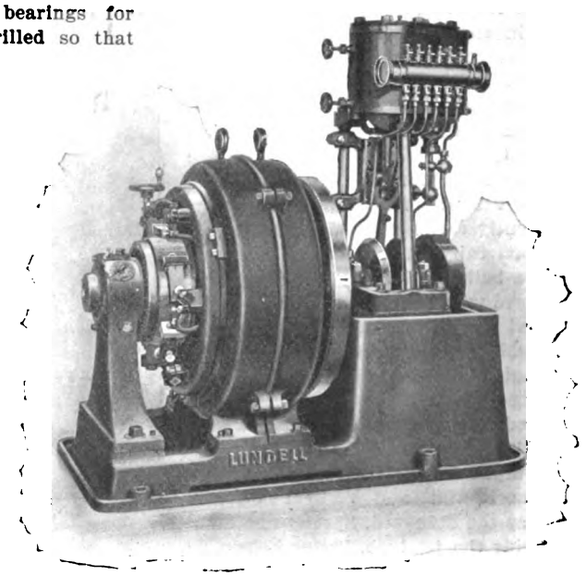
It will be observed that the frame of the motor is spherical, and provided with two circular bands which are turned true to gauge, and drilled uniformly all around the bands to enable the supporting foot to be attached at various angles, so that the motor can be attached to ceiling or side wall, either right or left handed, and at various other angles. The supporting foot can be made in any special shape desired to enable motor to be coupled to special machinery. The bearings for the back gear are also drilled so that same can be attached to the body of motor frame at any position desired.

The makers claim the great advantage in this arrangement is that a very slow speed can be obtained from the back gear shaft with a comparatively small motor, which results in the cost of outfit being very much less than is the case where a large motor frame is wound to obtain slow speed, and the efficiency of motor is also very much higher.

The back gear enables slow speed to be obtained directly from motor, without the necessity of a countershaft and extra belt, which are expensive as well as troublesome to maintain.



Where motor is to be installed in dirty places and exposed to flying particles, the heads are entirely housed.

These motors are multipolar, having four poles, and are constructed with wrought iron field cores, and the slotted core type of armature. The armature windings are form wound and insulated before being placed on armature. The parts of this machine are interchangeable and the bearings self-oiling, the same high grade of workmanship being maintained throughout as has won for the "Jenney" apparatus such a high reputation.

These machines are now made in sizes from ½ to 5 h. p. inclusive, for both moderate and slow speeds and for all standard voltages, and the company reports that it will soon be in shape to furnish this same type of machine in larger sizes.

### A LUNDELL DIRECT COUPLER GENERATOR.

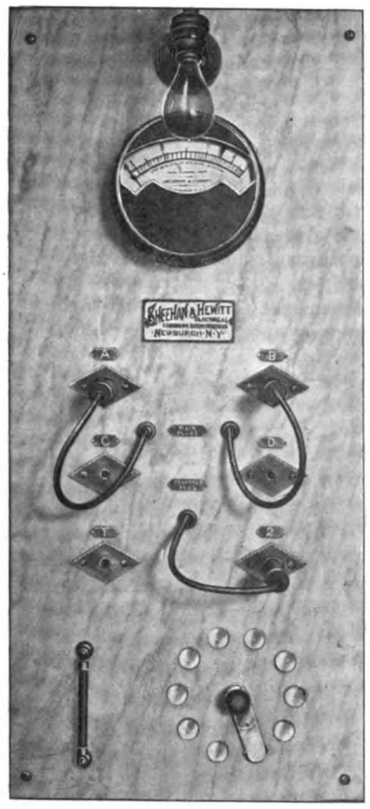
The illustration shows a Lundell generator driven by direct connection to a Forbes marine type engine. The rating of the generator shown is nominally of 8 kw. capacity, when running at a speed of 500 r. p. m. The set from which this photograph was made has been installed on the steam yacht "Postmaster General," now doing duty in New York Harbor.

A DIRECT COUPLED MARINE TYPE GENERATING SET.

When the plant was installed an exhaustive test was made, which showed that the apparatus is capable of developing 10.8 kw., sufficient to supply 216 lamps. The primary qualities in a direct-connected set for marine work, especially in yachts and similar classes of vessels, are compactness, light weight, ability to stand overloads and accessibility, which are met in this set, of which the total weight is only 1050 lbs., or about 100 lbs. per kw. output. The amount of space taken is small, being 27 in. wide by 6 ft. 2 in. long, the height being 38 in.

The ability of the generator to carry an overload, without sparking at the brushes, is due to the series wound armature and the use of a single field coil, which magnetizes all the different field poles to the same degree of intensity. The magnetic circuit is very short, requiring less copper to energize the field, and thus conduces to high efficiency.

The Sprague Electric Company, New York, is supplying these direct connected types in the following sizes, 8 kw., 16 kw. and 32 kw., generating current for 160, 320 and 640 lamps respectively.



---

### A SERIES GOVERNOR BOARD.

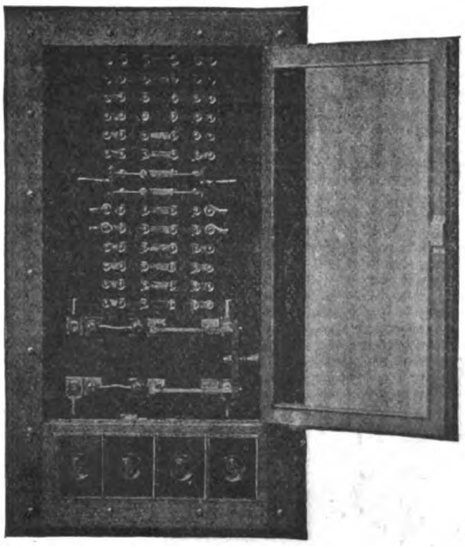
A marble switchboard panel fitted for the control of the current to a series circuit of incandescent lamps connected across constant potential mains is shown in the adjoining figure. The peculiarity of this board is the fact that the main steps of the regulation are effected by flexibly connected plugs, of which there

Digitized by Google

are three, fitting into six jacks. These are connected with transformers giving various different voltages in such a way that by combinations of the various plug positions and movements of the rotating switch in the lower right-hand corner

A SWITCHBOARD PANEL FOR SERIES INCANDESCENT CIRCUITS.

the circuit can be adjusted in one lamp steps for any number of lamps from one to 40 per cent. overload. The board is also equipped with an enclosed fuse, ammeter and pilot lamp. It is constructed by Sheehan & Hewitt, Newburgh, N. Y.

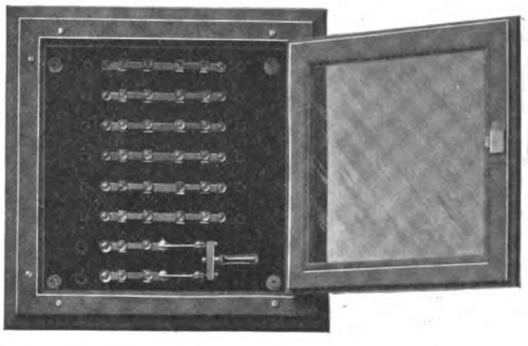


JUNCTION BOXES AND DISTRIBUTION PANELS.

The following illustrations represent the new type of junction box manufactured by Johnson & Morton, Utica, N. Y.

The tablet board containing the fittings of the box is removable and can be placed in the box after all the wiring is installed and after the interior finish of the building is completed, thus preventing any possibility of damage to the finish of the visible parts of the box. The concealed wiring pocket allows the wires to be brought in through the back, top, bottom or sides of the box, as may be most convenient, making the box standard independent of the location of outlets.

All of the branch circuits are supplied with detachable fuse holders, consisting of insulating bars with heavy copper ends, which make sliding contact in substantial jaws. The use of this holder enables the replacing of fuses while current is on the box, without danger of short circuiting or burning. The boxes are all standard width regardless of the number of circuits, and are so designed that they will fit between the uprights in ordinary wooden buildings without any cutting.

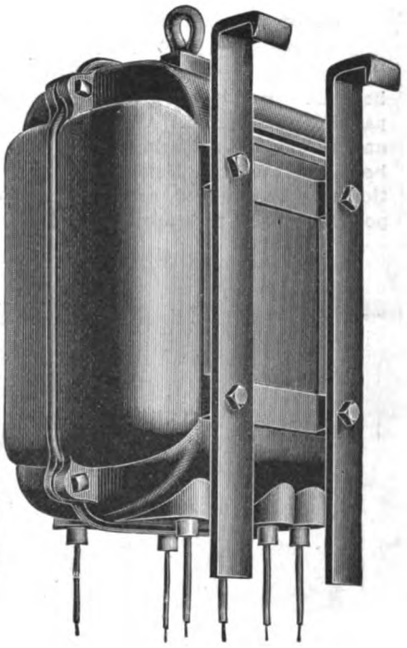


One cut shows a standard box containing a six-circuit tablet board with main

PANEL BOX WITH KNIFE SWITCHES, FUSES AND METER CONNECTIONS.

switch, but with no branch switches. It is intended for use at distributing points when it is desirable to disconnect the circuits supplied from the box and have the switch, fuses and all conducting parts under lock and key.

Another box is made of the same type, but provided with branch circuit knife switches and meter connections. This is intended for use in dwellings and small installations. The service mains are brought to the main fuses and switch, the current passing from here by means of



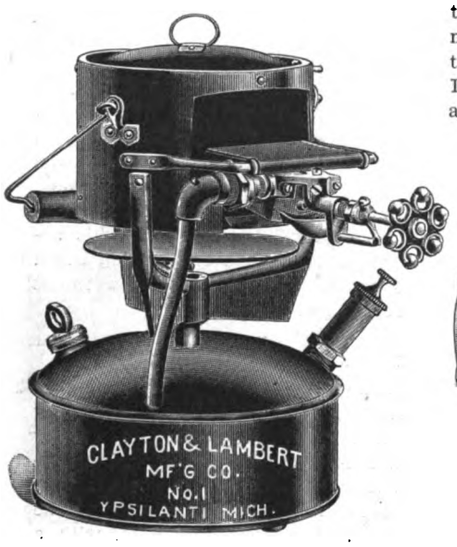
TABLET BOARD WITH ONE MAIN SWITCH.

the meter connections through the meter and back to the bus bars of the box. This complies with the underwriters' requirements for main entrance switch and cut-out, permits the use of a meter and concentrates all parts in the junction box. The branch circuit knife switches permit the disconnecting of any circuit and all parts are under lock and key. The arrangement of the main switch and meter connection can be supplied with any of the boxes whether they have branch switches or not.

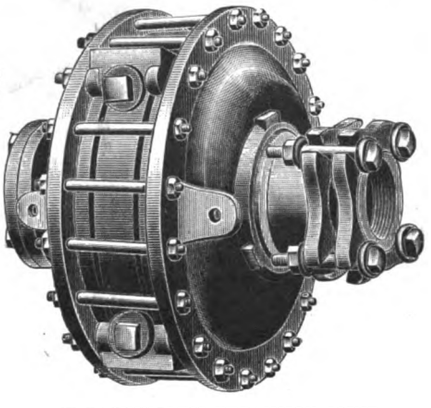
The other cut shows a standard box adapted for use in public buildings of medium size, such as school houses using commercial power. It contains main switch with fuses and connections for the meter, and two knife switches, each controlling three branch circuits supplying different sections of the building, also four branch circuit flush switches for controling circuits in the immediate vicinity of the box. The main switch and section switches can not be tampered with when the door is locked, but the panel of the door being of glass can be easily broken in case of an emergency when it is necessary to shut off the current. This arrangement combines a distributing board and junction box in a most convenient and economical manner.

MOLONEY TYPE A TRANSFORMERS.

Working on the general principle that perfection in one line is attainable only by excluding all other lines, the Moloney Electric Company of St. Louis, Mo., devotes its efforts exclusively to the construction of its type A transformers. The instrument is of the core type, with a cover divided in a vertical plane, as the illustration shows, and without an interior terminal plate; the change of connections to obtain 50 or 100 volts secondary or 1000 or 2000 volts primary being effected outside the case. It is modestly rated so that it can stand an overload of 25 per cent. The cores are compressed under a very high pressure and the wind-

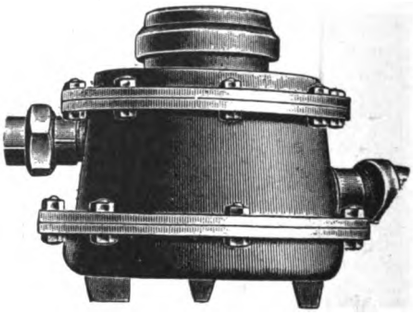


VIEW OF TRANSFORMER, SHOWING HANGER.



Digitized by Google

ing put on under an unusually high tension in order to eliminate any vibration of the parts with the alternating magnetism which might eventually fray the insulation.



The transformer is mounted on a simple hanger, readily attachable to cross arms or cleats and with each transformer order the company gives a pair of single pole non-arcing fuse blocks, having outside connections. The company also encourages the testing of transformers by consumers, and to assist this has published a pamphlet of instructions which it will be pleased to send to those interested.

A CONVENIENT FIRE POT OR TORCH.

THE PACKINGLESS EXPANSION JOINT.

THE STEAM METER.

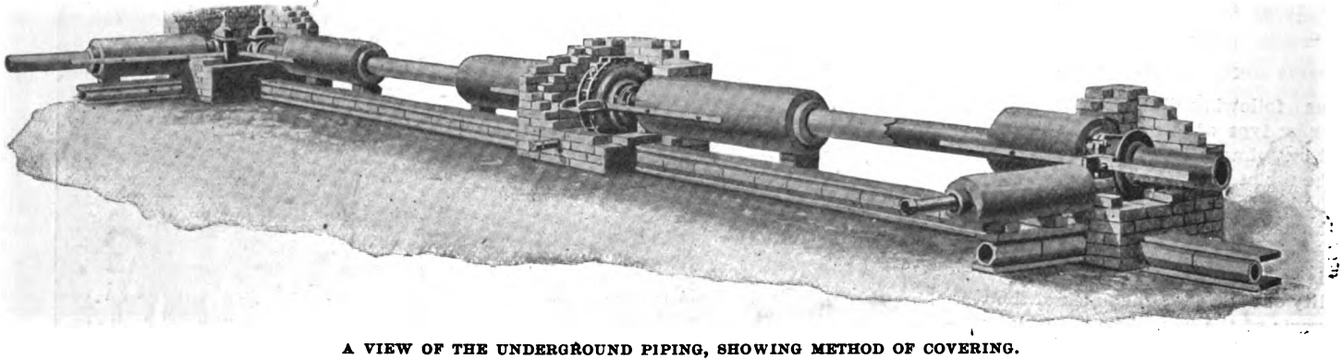
### A CONVERTIBLE FIRE POT AND TORCH.

A fire pot for which the claim is made that it will work satisfactorily in the heaviest wind is shown in the accompanying illustration. A kettle of solder and a pair of soldering irons can be heated at the same time, or the top section may be removed, converting the fire pot into a torch or brazing fire. The burner hangs on a swivel, so that it may be turned in any direction desired, and has a cast generator. It is made by the Clayton and Lambert Manufacturing Company, Ypsilanti, Mich.

### THE DISTRIBUTION OF EXHAUST STEAM FOR HEATING PURPOSES.

The development and utilization of by-products in many manufacturing lines have often quite revolutionized the industries, owing to fact that the by-products have often proven nearly as valuable, and in some cases more valuable, than the main product.

Central station work is fundamentally the manufacture of one form of energy, electric power, from another, fuel, the processes through which the energy passes giving several by-products. The greatest and most valuable of these is the heat usually thrown away in the exhaust steam from the engines. It is well known that the average engine only transforms into mechanical power about 10 per cent. of the energy given to the steam by the coal. The other 90 per cent., as a rule, is thrown away in the exhaust, while near the central station may be many low pressure steam heating plants with their uneconomical boilers and high cost of attendance generating what is thrown away at the station.



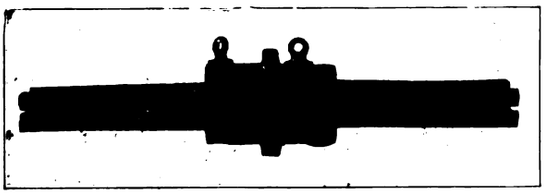
In condensing plants a slightly higher percentage, five to ten, of the heat energy in the steam is converted into mechanical work, but when the exhaust steam at or near atmospheric pressure can be sold for anything like the value of the equivalent fuel the loss due to non-condensing is many times refunded.

The American District Steam Company, Lockport, New York, has worked for years on the system designed by Mr. Birdsill Holly and has brought to great perfection the details by which the troubles of underground steam distribution are overcome. These troubles are condensation, leakage and expansion and contraction.

The system consists fundamentally of lap-welded wrought iron pipe, surounded by a 1-in. air space in bored white pine logs, lined with tin and coated with asphaltum, sometimes being further covered with 3-ply tar roofing felt. At intervals and especially where services are taken off, these pipes are coupled through special expansion joints with no sliding contacts, the expansion being taken up in flexible diaphragms so that no manholes are necessary to allow the packing to be attended to. The lines are laid with special care for drainage and have a tile drain pipe below them to carry off the drips.

The services are led through special reducing valves by which the pressure in the house system may be kept constant and also through meters ingeniously designed by Mr. Holly, wherein the steam impringes upon blades like those of anemometers, the speed being controlled by blades or fans in water to act as a brake. From such a meter the steam passes to direct radiators and from them to a cooling coil, over which cold air enters the house to give indirect radiation and ventilation. This extracts practically the last vestiges of heat from the condensed water, which is then trapped to the sewer.

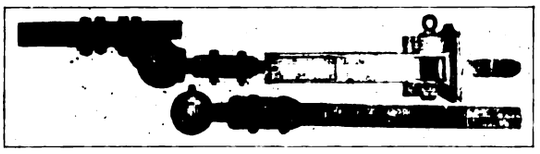
In a paper presented by Dr. M. M. Fenner before the last annual convention of the New York State Street Railway Association the results of the application of this system at the power station of the Dunkirk & Fredonia Railroad were given. Six per cent. dividends were paid, of which 3 per cent. came from the sale of exhaust steam, the steam being sold at a rate based upon the cost of equivalent fuel at $4 per ton of anthracite, or at a flat rate of $3 per 1000 cu. ft of space heated. Figuring roughly that the exhaust steam per h. p. continuous would heat



A VIEW OF THE UNDERGROUND PIPING, SHOWING METHOD OF COVERING.

Digitized by Google

10,000 cu. ft. of space in average buildings, this amounts to an income of about $30 per h. p. per season.



THE VAN DORN AUTOMATIC COUPLERS.

Following the lead of steam railroads, which have long ago discarded pin and link couplers for the passenger service, the street railways are rapidly adopting

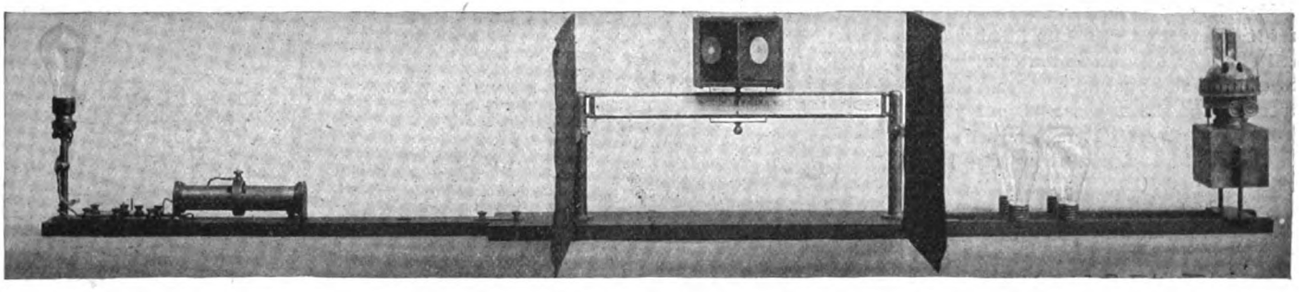
DRAWBAR HEADS OF THE VAN DORN COUPLER.

automatic coupling. The accompanying illustrations show devices of this nature made by the W. T. Van Dorn Company, Chicago, Ill. The first figure shows two of the draw bar heads closely coupled together, in which is clearly shown the two pin holes to each head by which the wear is distributed. The coupling bar is a separate piece and can be placed in either of the draw bar heads, so that when forced into the opposite head the springs therein will yield sufficiently to allow the hook to

COUPLER WITH BALL JOINT ATTACHMENT.

pass around the pin and fasten it. Each head has two or more springs constructed so as to do away with any liability of danger when coupled to any other class of couplers or the ordinary link.

The other illustration shows a coupling connected to the Van Dorn improved ball joint attachment, giving perfect flexibility in all directions and a ready means of adjusting the length. The ball of the joint is fitted with a pin so that the coupler cannot turn over. These couplings are made in ten sizes and styles adapted for surface, elevated, mining, dump or any other standard style of cars.



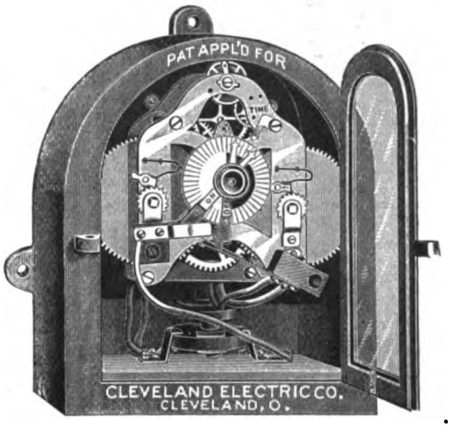
A PORTABLE PHOTOMETER FOR CENTRAL STATIONS AND LAMP SALESMEN.

Now that lamp buyers have become too critical to accept any incandescent lamp as having the candle power, voltage and efficiency marked on its label, the need of a means of testing is imperative. In the last issue of the American Electrician directions were given for the construction of a photometer, resembling closely that described below. The instrument complete is put on the market by the Electric Motor & Equipment Company, Newark, N. J., successor to the Newark Ornamental Iron & Sign Works, the well known makers of electrically illuminated signs.

The photometer is a knock-down instrument, 5 ft. in length when extended and capable of being packed into a space 24 ins. long by 6 ins. wide and 9 ins. high, and is made up in two styles, one for central station use and the other for salesmen, the former being somewhat stronger and the latter lighter.

The working standard of light is a duplex oil lamp, which is calibrated by the simple use of a primary standard placed in the socket in which the lamps are tested. These primary standards are special lamps made by the General Electric Lamp Works, seasoned and of low efficiency, and hence undergo very slow changes. By using one of these for a moment or two the oil lamp can be adjusted to the proper brilliancy at which it will run for hours without re-calibration.

The spot box is of the regular Bunsen grease spot type, with inclined mirrors and working over a celluloid scale. A small German silver resistance coil provides suitable means for adjusting the voltage over a range of about 15 per cent. Owing to the fact that the influence of extraneous light is more or less balanced out by the calibration of the working standard against the primary standard, placed in the position which the lamps to be tested subsequently occupy, no specially prepared dark room is necessary. The weight of the portable instrument is reduced to 12 pounds, complete in a canvas carrying case.



A PORTABLE PHOTOMETER.

THE CLEVELAND AUTOMATIC TIME SWITCH.

The value of a reliable switch for turning on and off lights at predetermined times, particularly for use on street lamp posts worked from constant potenial circuits carrying commercial loads, is self-evident.

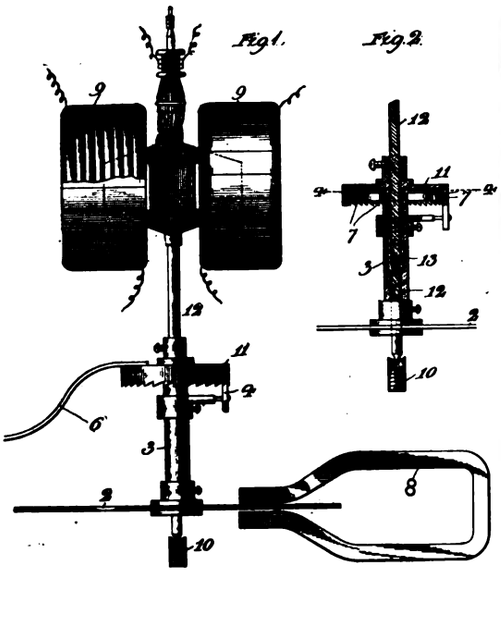
A new switch of this type is that shown in the accompanying illustration and made by the Cleveland Electric Company, Cleveland, Ohio. It consists primarily of an 8-day Seth Thomas clock, fitted with a 24-hour stem on which is centered a time dial and two independent pointers. The contact of one of these with an appropriate piece closes the circuit through a solenoid, which operates the switch, the movement of its armature immediately breaking the circuit with the pointer by moving the piece with which it makes contact. The same motion places in position the appropriate contact for the other pointer, which in turn is removed and the

AN AUTOMATIC TIME SWITCH.

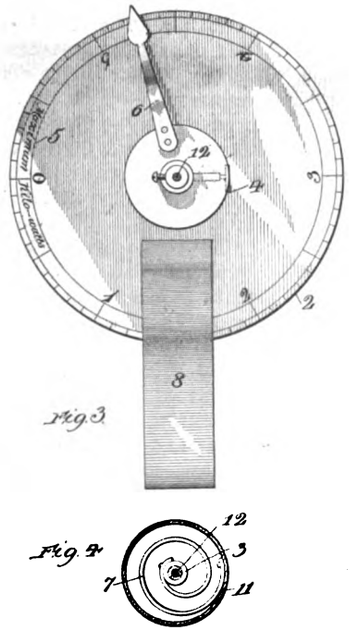
circuit broken as soon as the reverse operation of the main switch is made.

The Cleveland Electric Company also makes a high tension series arc cut out. The affairs of the company are under the management of Mr. Edwin M. Smith, a novice in the electrical field, but with an inclination to enlarge the circle of his acquaintances.

A COMBINED MAXIMUM DEMAND AND INTEGRATING METER.



The great interest taken among central stations in discount systems based upon the ratio of the average to the maximum demand has brought out several instruments for indicating the maximum current used on circuits, in addition to the usual integrating meter for showing the average demand. A device for combining the two indications in one instrument is shown in the accompanying drawings; a meter built on this principle being



Digitized by Google

shown complete in the half-tone illustration.

The upper or motor part of the shaft of the meter drives the lower or dragging disc part through a spiral spring 7, which is shown separately in Fig. 4. The deflection of this spring is proportional to the drag of the motor upon the brake disc and consequently to the load drawn through the meter. Fixed to the upper shaft is a fine ratchet, 11, and on the lower shaft is a pawl engaging therewith so that the spring once deflected cannot restore itself; thus the maximum load upon the meter will cause a maximum deflection of the spring, which will remain until the pawl is released from the ratchet by hand. This reflection will be indicated by the pointer, 6, upon a scale on the edge of the brake disc, which is clearly shown in the photographic reproduction.

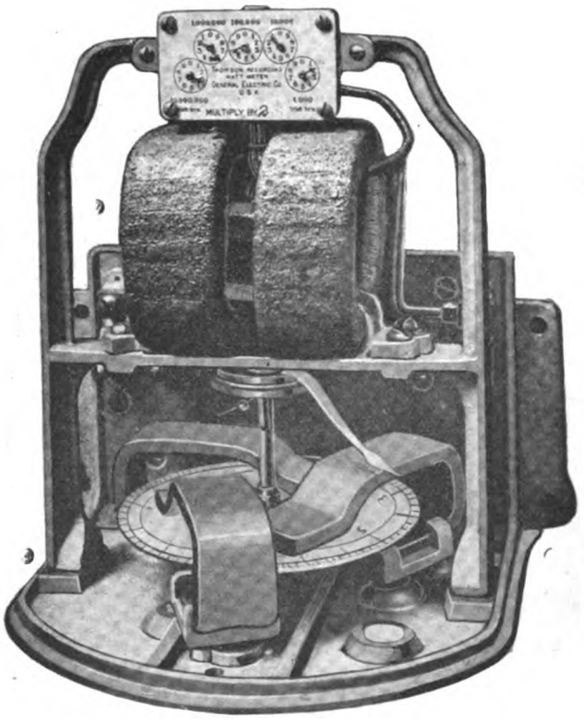
To prevent sudden brief overloads from recording themselves the lower end, 13, see Fig. 2, of the upper section of the shaft is seated in a deep cup filled with a small quantity of viscous material which acts as a brake against sudden relative movements of the two shafts, but yields to continued stress. It is interesting to note that in this material there is so little friction of rest that the indicator will move with less torque than that required to revolve the disc. The increase in weight of the revolving parts in the case of a Thomson meter is only about 4 per cent. The instrument is the design of Mr. Edward S. Halsey, 139 Adams Street, Chcago.

DETAILS OF A COMBINED INTEGRATING AND MAXIMUM RECORDING METER.

### AN ELECTRIC GAS LIGHTER.

Among the many inventions for lighting gas by electricity, the most used is the valve pendant burner, of which there are quite a number on the market, among them the Jypco, a cut of which is here shown.

This burner is made out of one solid piece of brass, with a spiral spring electrode attached to burner arm, making it easy of operation. The special feature of this burner is the pull back spring, which unlike spiral springs, exerts no tilting strain on the valve; also the arrangement used for preventing short circuits, which not only makes the burner ground proof, but prevents leakage of gas resulting from any accident that may happen to the burner.



It is manufactured by Messrs. John Y. Parke & Co., Philadelphia, who also make all kinds of common, acetylene and incandescent gas lighting appliances.

A PENDANT GAS LIGHTER.

### THE OTIS FEED WATER HEATER.

A surface heater and purifier of the tubular type in which the exhaust steam passes through the tubes and the feed water circulates around them is shown in partial section in the accompanying illustration, which clearly illustrates the arrangement of the parts. The exhaust enters at the top and passes downward to a chamber at the bottom of the heater exposed to cold feed water, where the water and oil remain owing to their weight and are thereby removed from the steam which, after it is condensed, can be used for boiler feeding without danger of introducing oil. The heater is made by the Stewart Heater Company, Buffalo, N. Y.

MAXIMUM RECORDING DEVICE COMBINED WITH THOMSON WATTMETER.

A PORTABLE CABLE TESTING OUTFIT.

The firm of Queen & Co., Inc., Philadelphia, has placed on the market a new portable cable testing outfit which is a decided departure from anything heretofore produced, and is so constructed as to facilitate in every possible way the usual measurements on cables. The complete outfit comprises a testing case, galvonometer, tripod, extra system, camp stool and heavy leather carrying case, which contains everything when packed.

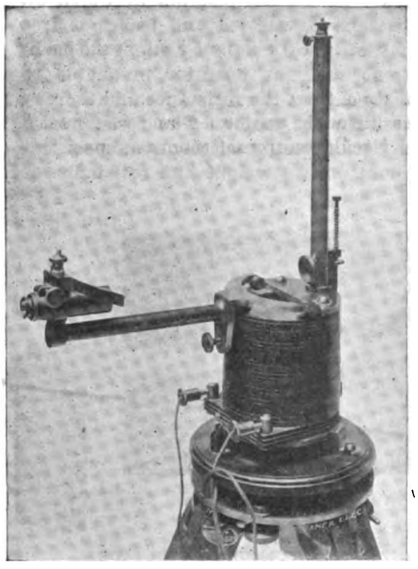

FIG. 2.—GALVANOMETER ON TRIPOD.

The galvanometer illustrated in Fig. 2 is of the well known Queen pattern fitted, as shown, with telescope and scale. As will be noticed, the telescope arm and scale are very short, thereby rendering it compact and stable. The scale is a photographic one and, although less than five inches long, is so finely graduated and highly magnified as to permit of as accurate reading of the deflection as with the usual meter scale and long distance. The galvonometer is held on to the tripod by a spring screw, which while securely supporting it, permits it to be easily and quickly leveled. Leveling screws and a sensitive level assist in its rapid adjustment. All necessary adjustments are supplied on telescope and scale. The tripod is one of the transit tripods, which when closed is very short, yet when open, perfectly solid.

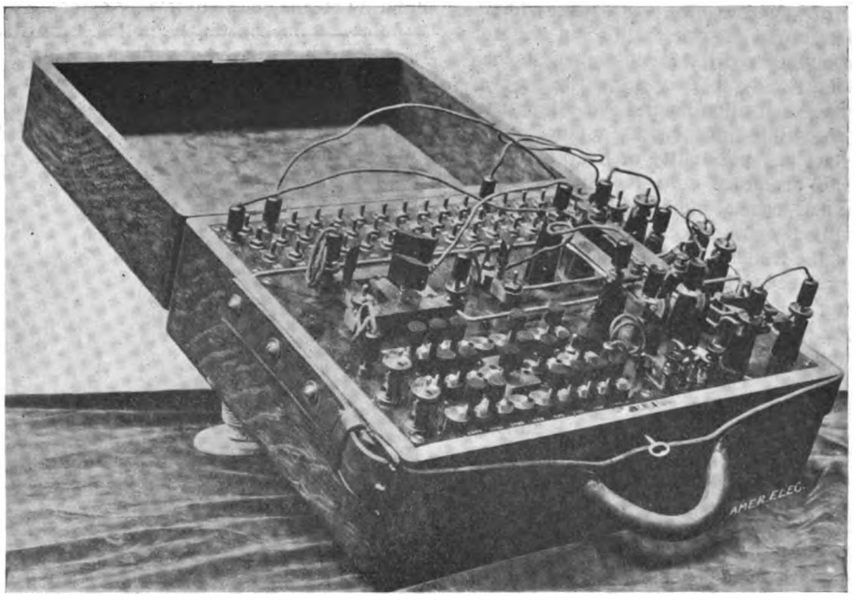

FIG. 3.—THE TESTING CASE.

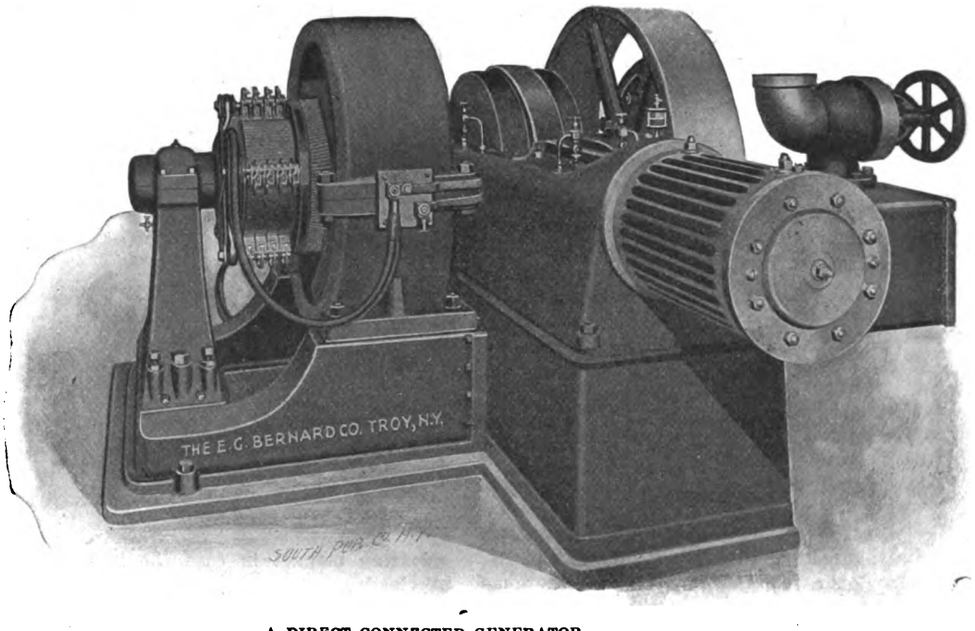

The testing case is illustrated in Fig. 3. It contains everything for making Wheatstone bridge resistance measurements, direct deflection insulation measurements, capacity tests, and the Varley and Murray loop tests; also if desired insulation measurements by loss of charge.

High insulation is secured throughout by means of polished and corrugated hard rubber pillars. All connections are in sight and made by means of copper rods run clear of everything. For any test requiring high insulation there is no low insulation point permitting leakage. For example, when the Wheatstone bridge is not in use it is entirely cut out by means of a switch, thereby not vitiating the capacity or insulation tests.

The insulation of all contacts under the rubber base is kept high by running the hard rubber pillars clear through and corrugating below as well as above the rubber plate. The galvanometer when used ballistically gives deflections strictly proportional to the discharge. When used for direct deflection measurements the deflections are strictly proportional to the current and it is thoroughly dead-beat.

FIG. 1.—THE SET IN USE.

A DIRECT CONNECTED GENERATOR.

DIRECT-CONNECTED MULTIPOLAR GENERATOR.

The direct-connected generator shown in the accompanying engraving is designed for high electrical efficiency with-

Digitized by Google

out sacrifice of any of the properties upon which the smooth running of the machine under practical conditions are dependent. The mechanical features have received special consideration, the commutator being of generous size, the brushes having a large area of contact and the armature thoroughly ventilated through both longitudinal and radial openings. The bearings are self-aligning and self-oiling, easily accessible and of such a length as to obviate any possibility of heating.

The armature core is constructed of discs of special non-hysteric iron thoroughly tested and carefully annealed. It is of the ironclad type, the conductors being imbedded below the surface in insulating tubes made up of mica and oiled paper. The coils are machine wound, absolutely symmetrical and so aranged that no conductors cross having betwen them a high difference of potential. The commutator is also ventilated and is fully 20 per cent. larger than the commutator on usual types of similar machines of the same size. The brush holder is of the reaction type and the brushes adjust themselves to a bearing with minimum friction, while at the same time they are kept in perfect contact with the holder. A brush can be easily replaced in five to ten seconds while the machine is in operation. The brush contact area is based on about 25 amperes per square inch of carbon brush, this being from 20 to 40 per cent. more than is the usual practice. The result of the care taken in the design and selection of materials is a machine of slow speed and high efficiency, that will run sparkless and perfectly cool under normal load, require a minimum of attendance and withstand a more considerable overload than is usual with machines of the same efficiency. The manufacturer of the direct-connected generator described is the E. G. Bernard Company, Troy, N. Y.

---

### MOTOR CONTROLLERS.

In the early use of electric motors for power distribution the motor itself was simply called upon to revolve and give power at a fixed speed. The adaptation of this power to the machines driven was effected by belts, cone pulleys, friction clutches, etc. Now that motors are direct coupled or direct geared to machines the speed or torque control, starting, stopping, etc., must be arranged for in the electric circuits instead of in the mechanical connections. Different types of machines involve different requirements, necessitating a large number of different controllers. Of these the Cutler-Hammer Manufacturing Company of Chicago, Ill., makes a remarkably complete line, some of the newest instruments of which are illustrated herewith.

Fig. 1 shows what is called a compound controller for large printing presses. The rheostat arm is fitted for controlling the speed of the motor by three different methods. In starting it first cuts out the armature resistance, then cuts out the series coils of the motor field and finally inserts resistance in the shunt field circuit. Below this rotating arm on the controller is the main switch, consisting of a horizontal arm pivoted at its center, the two ends constituting the two knives of a double pole switch. This is closed by hand by means of the upwardly extending handle and is constantly pulled toward the open position by coiled springs.

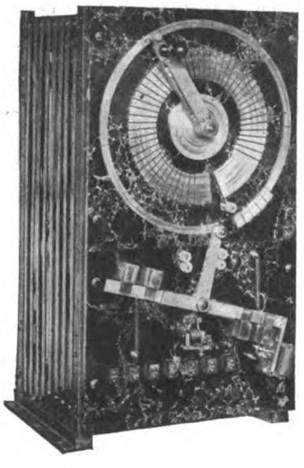

FIG. 1.—A PRINTING PRESS CONTROLLER.

When closed it is latched by the armature of a small magnet connected up with a number of switch buttons and contacts arranged to be automatically closed by broken paper or other mishap. The operation of this magnet releases the arm which is pulled into the open position by the springs. A small overload magnet also acts as a relay to operate the same releasing magnet in case the motor is overloaded.

Fig. 2 shows what is termed a reversible controller, which is designed for cranes or hoists, and consists of a long arm linked with a four-arm dial switch, which serves in the usual way to reverse the armature connections. Pinned to the end of one of these four arms is a connecting rod which serves to push upwardly a crosshead carrying carbon contacts on the rheostat connections at the top of the controller. The connecting rod is slotted so that the rotating switch arm can only push the crosshead up, but cannot pull it down. It falls by gravity and its speed is controlled by a dash pot. When, therefore, the controller is reversed it pushes the crosshead up quickly to the top position in which all resistance is inserted and leaves it free to fall of its own weight against the dashpot, so that the operator is unable to quickly cut out the resistance and thereby overstrain the motor. The resistance is thus cut out automatically at a speed dependent on the weight and resistance of the dash pot, starting the motor smoothly at the proper rate of acceleration.

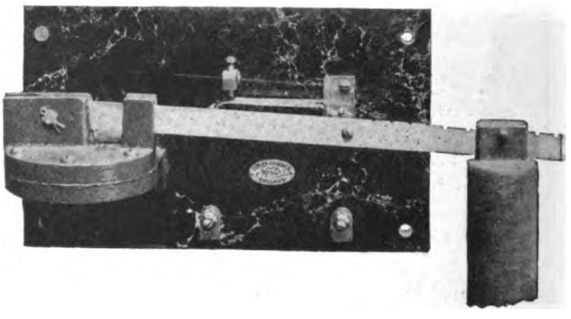

FIG. 4.—AN AUTOMATIC PRESSURE REGULATOR.

Fig. 3 shows an ingenious instrument applicable to many various uses and termed a self starter. It consists of a solenoid designed to attract a vertical plunger, which is connected with an L-shaped pivoted casting. The two arms of the L constitute the two poles of a double pole main switch with laminated copper contacts and secondary or following breaks of carbon. This is operated with a quick snap whenever the circuit of the solenoid coil is made or broken. The armature of the solenoid is also connected through a coiled spring with a crosshead at the bottom of the controller, carrying the contacts on the rheostat segments. When the armature rises suddenly, closing the main switch described above, it compresses this spring, which gradually

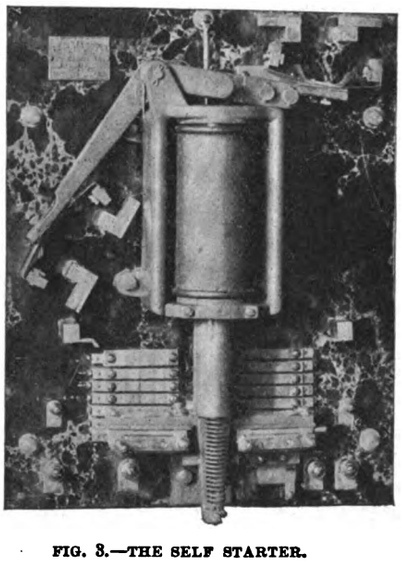

FIG. 3.—THE SELF STARTER.

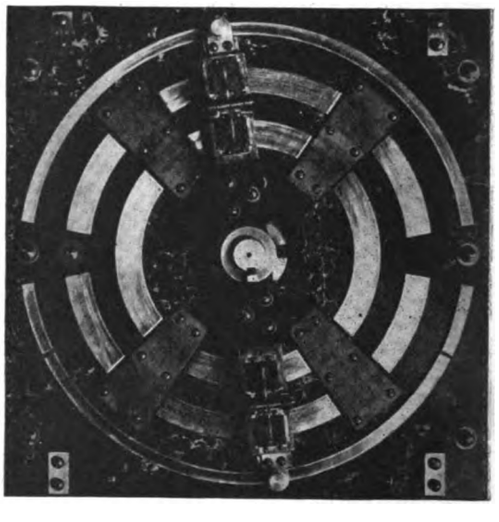

FIG. 5.—A REVERSING SWITCH FOR ELEVATORS

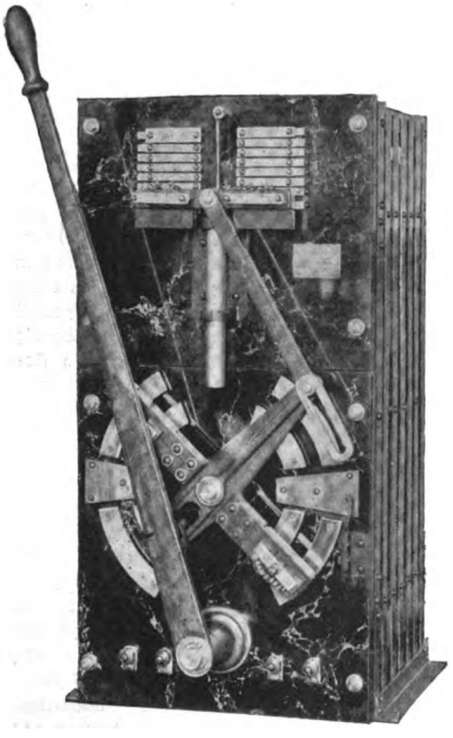
Digitized by Google

forces up the rheostat crosshead, which is fitted with a retarding device so that the resistance cannot be cut out too rapidly. The circuit of the solenoid windings is necessarily closed while the motor is running, but the moving parts are fitted with contacts whereby—when the armature has risen and the magnetism need only be maintained at sufficient strength to hold



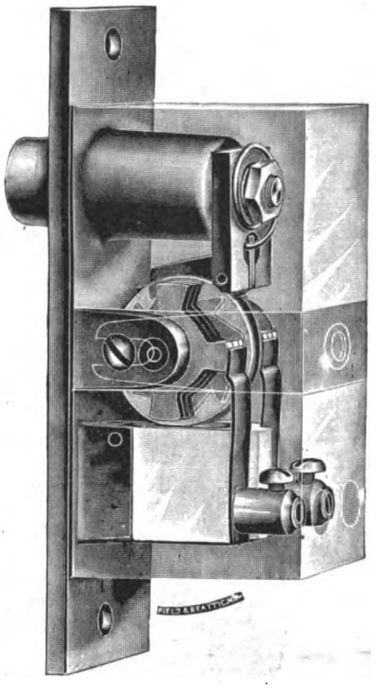


FIG. 2.—A REVERSIBLE CONTROLLER.

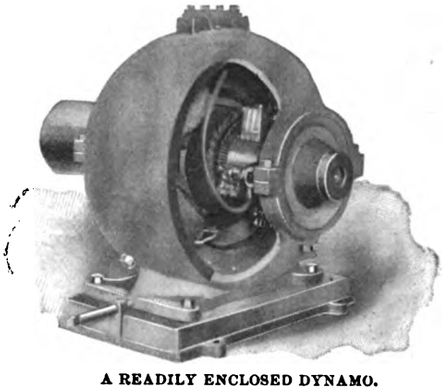
it in the upper position—the current is greatly reduced, thus cutting down the waste of energy to a negligible quantity.

This instrument is applicable to elevators, motor driven pumps or other apparatus where it is desirable to start and stop a motor automatically. For pump service it may be combined with any float switch whose contacts need only control the small current taken by the solenoid windings, instead of the main current of the motor. For motors used in obtaining a constant pressure, either hydraulic or pneumatic, the pressure regulator shown in Fig. 4 may be used on the same self starter. This consists of a diaphragm forcing upwardly a weighted lever and operating a small snap switch on the circuit of the solenoid of the self starter. For elevator service the same self starter may be used with a reversing switch, such as is shown in Fig. 5. Here the two inner rings operate to reverse the armature connections in the ordinary way, while the outer rings send current to the solenoid of the self starter when the reversing switch is in either the up or down running position.

### A NOVEL DOOR SWITCH.

A switch designed for turning on the lights of telephone booths, toilets, etc., when occupied, and turning them off when unoccupied, whether the door is open or closed, invented by Mr. A. Lüngen, is shown in an adjoining figure, and is made by Edwards & Company, New York City. It is called the Eco Door Switch, and is the first electric light fitting which this firm, well known through its electrical house goods, has manufactured. The object of the switch is to turn on the light when the door is opened and closed



AN AUTOMATIC DOOR SWITCH.

and turn it off again the next time the door is opened and closed, so that the light will be left on when a person enters the apartment in which it is placed, and turned off again when the apartment is vacated. It differs in this respect from previous door switches, which, as is well known, are arranged to turn the light on when the door is closed and turn it off when the door is open, wasting considerable current if the door is closed with no one inside. The new switch is provided with porcelain insulation and a porcelain cover, and has been approved by the National Board of Fire Underwriters. Its size is such that it can be used on any door frame.

### A LINE OF SPHERICAL OPEN OR ENCLOSED DYNAMOS AND MOTORS.

In modern dynamo design small machines are built so that by the addition of covers over the openings, the same machines can be converted from the open to the enclosed type, with the appropriate reduction of rating to prevent overheating in the unventilated condition necessitated by the enclosure. Such a machine is made by Roth Bros. & Company, Chicago, Ill., possessing several ingenious details described below and is illustrated herewith.

The frame or magnet yoke is of cast-iron and is cast integral with four extensions or arms to hold the bearings, which are of a peculiar design, sufficiently large to permit the removal of the armature endwise through the openings they leave when removed from the encircling arms. The yoke is not split, but the arms are, in order that they may be clamped tightly on the bearings, which may be rotated

A READILY ENCLOSED DYNAMO.

to bring the oiling wells in the proper position, whether the machine is run on the floor, ceiling or wall. The magnet poles are of soft cast-steel, bolted to the yoke, and fitted with pole shoes to reduce the density at the air gap.

### AN AUTOMATIC ADJUSTABLE ELECTROLIER.

An illustration appearing on this page shows an automatic supporting electrolier for the adjustment of incandescent electric lights to various heights. It is of the spring balance type, composed of a porcelain base upon which are mounted two

AN AUTOMATIC ELECTROLIER.

standards supporting a drum upon which the cord is wound, the cord being electrically connected to each pole of the drum. Each standard is connected by a fuse to the main contact pieces, thereby taking the place of the fuse rosette in common use. Two hooks are provided to make contact with line wires for outside or moulding wiring. There are also two holes in the porcelain base to bring

Digitized by Google

through the wires for concealed wiring, the whole being enclosed in a brass shell (made in four different finishes, silver striped, bronze striped, brass striped and polished brass). The action is the same as that of the common spring balance curtain. It has no unsightly loops of cord or balls to swing light after being adjusted.

---

"DIAMOND H" PUSH BUTTON SWITCHES.

It would seem that the demand for push button switches has been more than satisfied by the various types upon the market, and that very little improvement could be made in switches of this class. The "Diamond H." line of push button switches has many points of merit which will commend themselves to all who examine it much more forcibly than can be done by a written description.

Fig. 1 shows the switch as a whole with a solid brass face plate. The ears for attaching the switch to the wall or woodwork are recessed in the back of the face plate, avoiding the necessity of cutting a recess in the wall for them. Fig. 2 is a 10 ampere double pole switch with face plate removed. The mechanism and contacts are enclosed in a porcelain base, shown with the front side cut away. The switch plates, one of which is shown in the cut, are of the knife pattern, and owing to the device for driving same into and out of the contact clips, a high velocity and consequently a short arc are assured. The contact, Fig. 3, is of phosphor bronze attached to a brass upright, which carries the binding screw. The phosphor bronze clip is comparatively long and wide, which insures flexibility and firm pressure upon the end of the switch plate. The spring, Fig. 4, is a simple coiled spring of comparatively large diameter made of steel music wire, with upturned ends to engage the moving parts of the switch.

The insulation of the current carrying parts is effected by spools made of sheet mica, laminated, and held together by a central bushing. This spool is shown in section in Fig. 5. It is loosely mounted in an elongated opening in the switch plate, and is driven by a pin through its central opening. The body of the spool is surrounded by a steel sleeve, thus preventing the edges of the opening in the switch plate from cutting the mica. The movement of the buttons is smooth and the pressure required is uniform throughout their travel and nothing else has been sacrificed to secure this end. Details of less importance than those referred to have been carefully considered and the result is a switch which the manufacturer, the Hart Manufacturing Company, Hartford, Conn., believes to be thoroughly good and reliable.

## NEW BOOKS.

---

Liquid Air and the Liquefaction of Gases, by T. O'Conor Sloane, New York. Norman W. Henley & Co. 365 pages. Illustrated. Price $2.50.

The appearance of this new work is most timely, the greatest interest having been excited within the last few months in this subject, about which little is known and less published. The treatment of the subject consists largely of historical accounts of the developments made by the different workers in the field, such as Michael Faraday, Raoul Pictet, Louis-Paul Cailletet, Jas. Dewar, Chas. E. Tripler and others, prefaced by four chapters intended to give the lay reader a good ground work of the fundamental laws of physics, heat and gases that apply to the subject of the book. Following the historical section are three chapters describing most clearly the various methods of obtaining liquefied air, the description being illuminated and rendered remarkably intelligible by ample illustrations. Another chapter which is as fascinating as a work of fiction is that on experiments with liquid air and still another that is largely speculative and prophetic is entitled "Some of the Applications of Low Temperatures."

---

American Electrical Cases, edited by Wm. W. Morrill. Albany, N. Y. Matthew Bender. Six volumes. Price $6 per volume, $36 for the set

This elaborate work comprises a collection of all the important cases, excepting patent litigation, in the State and Federal courts from 1873 to 1897, on subjects relating to the telegraph, the telephone, electric light and power, electric railway and other uses of electricity. There is perhaps no other single work which contains as much of value for use in the legal departments of electric and street railway companies. It contains full reports of between two thousand and three thousand cases, among them actions treating of the powers of municipal corporations over the streets and highways, the rights of the municipalities to impose license fees, the rights of abutting property owners, the cutting of trees, the rights of the telegraph along the steam railroad, the crossing of electrical and steam railroads, the interference of different companies in the use of the same streets, the various phases of negligence, such as injuries to employees or others by electric shock or otherwise, the duties of street railway companies to passengers and to others using the street, the taxation of companies and their property, the rights of municipalities to supply electric light, the negligence of telegraph companies in sending messages, etc., etc. A work of this sort not only gives valuable information upon specific questions of law, but is invaluable as a reference work, as figures obtained from it show the general tendency of the law and serve in this way for the preparation of arguments.

---

Steam Engine Indicator. By F. R. Low. New York: The Power Publishing Company. 203 pages, illustrated. Price $1.50.

With the increasing use of direct connected electric lighting sets of larger and larger sizes there arises a greater need of accurate cylinder indication to give any idea of the mechanical input of the combined mechanism, the output of which can be measured with electrical instruments. Unfortunately for the accurate determination of efficiency and location of losses the steam engine indicator is inherently subject to many more errors than are electric measuring instruments, so that accurate engine indication is an art requiring considerable study and skill. The work above mentioned is a complete and thorough treatise on the subject, compiled from the regular issues of "Power," giving complete descriptions of all the apparatus involved in indicator measurements with instructions as to its use and an analysis of the results obtainable, and particularly of the errors which enter into these results and the corrections which may be applied.

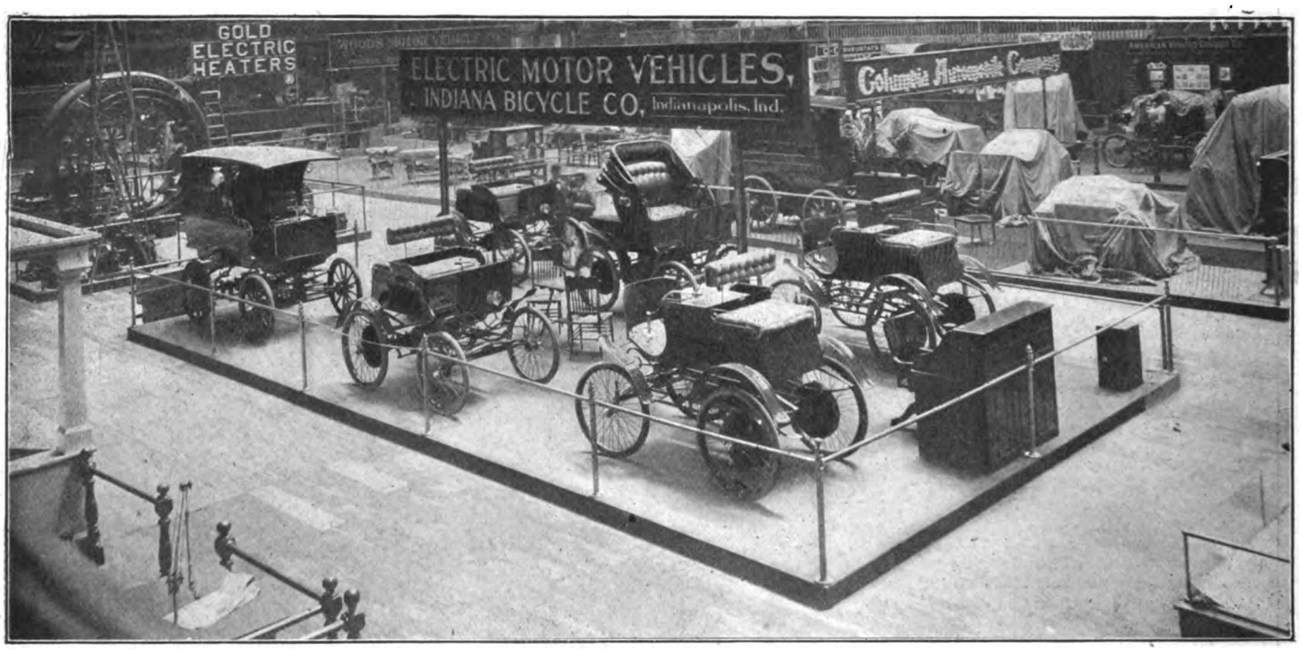
# THE 1899 ELECTRICAL EXHIBITION.



The third electrical show opened in Madison Square Garden, New York City, with its usual brilliancy, upon the evening of May 8th, with an attendance of several thousand people. Thanks to the efforts of its officers it contains the first general exhibition of automobiles. To those who can afford pleasure vehicles of this at present rather luxurious type, this feature of the exhibition evidently appeals strongly, if one may judge from the intelligent interest in the questions of cost, life, capabilities, etc., a large part of which is evidently not pure curiosity, but the outcome of a desire to determine, before purchasing, the relative merits of the different makes. The very fact that this is the first automobile exhibition in this country and that all the vehicles are electrical is an indication of the tendency toward the use of that power in preference to all others.

The illumination of the garden was this year put in the hands of Mr. Luther Stieringer and is unusually successful. The lighting is effected entirely by means of frosted incandescent lamps, some outlining the trusses of the roof, as usual, supplemented by 32 hanging clusters of 16 lights each, and other clusters in the galleries.

Outside of the exhibits of manufacturers and dealers, notes of which will be found on the following pages, the features of general interest are the government exhibit, the collection of historical arc lamps, wireless telegraphy, the transmission of sound by means of a radiophone, the cave of the winds, the Bell theatrophone, the theatre lighting exhibit, the Wehnelt interrupter and the Roentgen ray exhibit in the grotto.

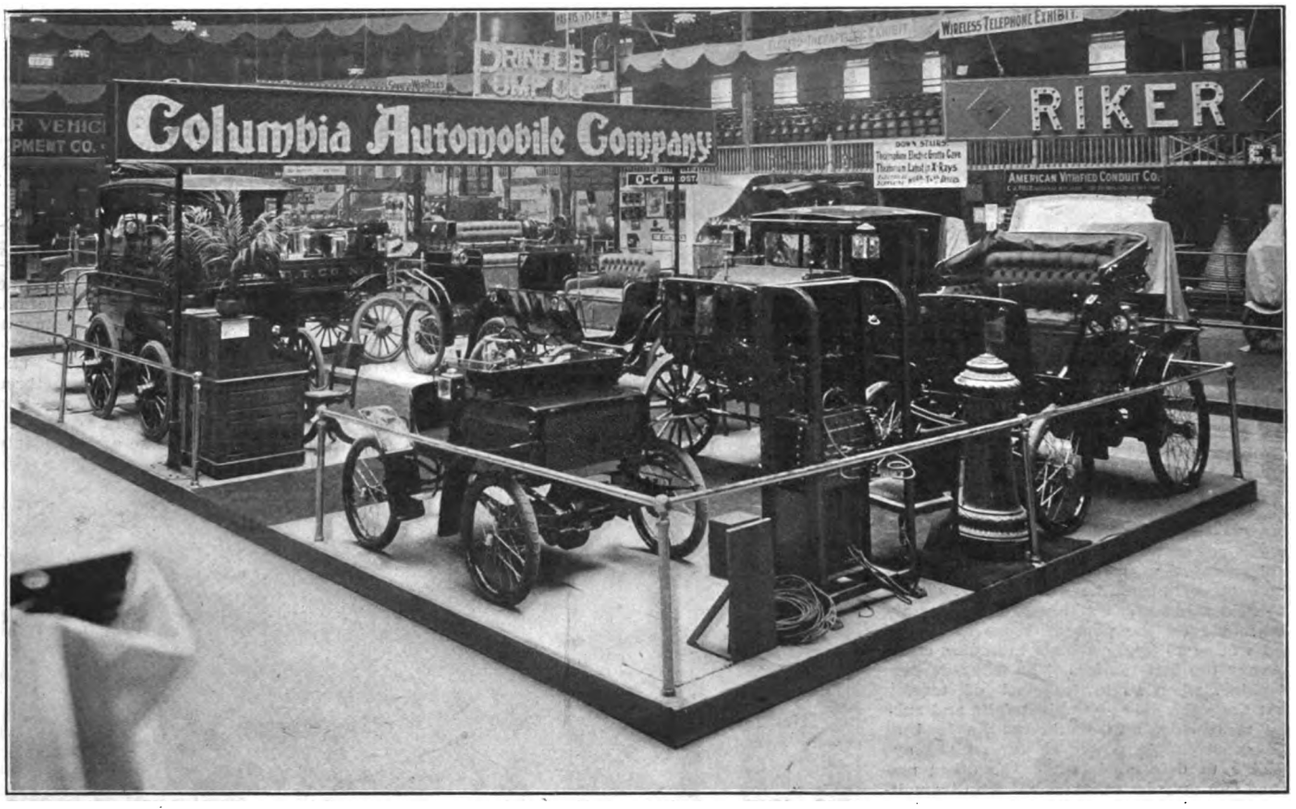
THE WAVERLEY ELECTRIC AUTOMOBILES.

THE INDIANA BICYCLE COMPANY, Indianapolis, Ind., has a striking line of Waverley carriages, the first general exhibit of its output in New York City. The company manufactures these equipments complete with the sole exception of the woodwork, constructing in its own shops the batteries, motors, tires, etc. The vehicles are all supported on stiff running gears of cold drawn seamless steel tubing, each member of this gear or truck being two tubes in height, constituting a stiff truss. The forward bolster is a strong diamond shaped arrangement of tubes swiveled to the gear through a vertical fifth wheel, giving flexibility when running over uneven roads, without straining the gear or body. All wheels are on ball bearings and fitted with single tube pneumatic tires, those of the lighter carriages having wire spokes and those of the heavier vehicles wooden spokes. Each vehicle is driven by one 4-pole motor of the circular yoke type with internally projecting laminated fields. On the armature shaft is a compensating gear of the well-known bevel pinion type, the ends of the shafting driving enclosed single reduction gears on the hubs. The brake is a band on the compensating gear. Five speeds are provided in the forward and three in the reverse direction by means of the usual series multiple arrangement of the batteries, a starting rheostat on the first notch and a field loop on the last. The reversing lever consists of a button projecting from the end of the controller handle and interlocked so that it can only be reversed in the off position. An emergency switch, consisting simply of a Yale lock with a

THE AMERICAN ELECTRIC VEHICLE COMPANY'S CARRIAGES.

Digitized by Google



switch attached thereto, is provided. The lighter vehicles are suported on reverse elliptic or X springs forward and double elliptics at the rear, while the heavier ones, including the delivery wagon, have platform springs. These heavier vehicles also have worm gears in the steering mechanism, doing away with any yanking of the operator's hands when running over obstructions.

THE AMERICAN ELECTRIC VEHICLE COMPANY, Chicago, Ill., shows one delivery wagon and one Stanhope. The latest types of this company's vehicles embody novel running gears consisting of a single reach between the motor at the rear and the forward bolster. The reach is swiveled in such a way as to give flexibility to the system. The vehicles are driven by one 4-pole circular yoke type motor, with a differential gear on the armature shaft opposite the commutator, the ends of the shaft meshing with ordinary single reduction gears and wheel hubs. The company makes its own storage batteries with plates of the rolled lead pasted type, which attain the remarkable output of 5.9 amperes per lb. of cell complete at a 5 hour discharge rate. A test was recently made by G. W. Knox, Electrical Engineer of the Chicago City Railway, on a vehicle of this company's make, which ran 61.5 miles with two passengers under ordinary conditions of road, weather, etc.

THE COLUMBIA AUTOMOBILE COMPANY, successors to the Motor Carriage Department of the Pope Manufacturing Company, has six vehicles in its space, a brougham, a runabout, a dos-a-dos, a victoria, a delivery wagon and an emergency or fire department wagon. Of these the brougham is a new and strikingly handsome vehicle, its main features being as follows: The battery is divided and located in two compartments, one beneath the driver's seat and the other behind the body. There is no direct connection between the forward and rear running gear, the strain of driving being removed from the springs by braces extending to the body from each axle-tree. The vehicle is driven by a single motor with compensating gear in the motor shaft, with pinions on the end of the shaft engaging with annular gears fastened to the wooden spokes of the wheels, which are fitted with solid rubber tires. Band brakes are mounted on the hubs within these annular gears.

A NEW ELECTRIC BROUGHAM.—Besides exhibits of its well-tried lines of automobiles—one a Victoria which has traveled some 8000 miles—the Riker Electric Motor Company of Brooklyn shows a new brougham designed for the fine trade. The general appearance of this vehicle is more pleasing than that of lighter electric vehicles, as the battery necessitates a lesser departure from horse-drawn types than it does in lighter automobiles. Its construction follows the standard Riker principles. The running gear is made up of steel tubing swiveled to the forward and rear axletrees, constituting a sort of flexible truck, on which the body rests through double elliptic springs at the rear and a reverse elliptic at the front, giving practically a 3-legged support. Wooden wheels, roller bearings and solid rubber tires are used. The steering mechanism is of the pivoted hub type, the pivots being within the hubs. Two Riker motors are used and drive through single reduction spur gears fastened directly to the spokes of the rear wheels. The gear cases are enclosed and within the same enclosures are band brakes operating on pulleys integral with the main gear wheels. The accumulator, which is of the chloride type, is divided into two portions, one behind the body and the other below the driver's seat. The total weight of the vehicle is about 4200 lbs.

I. T. E. CIRCUIT BREAKERS.—The Cutter Company of Philadelphia shows, besides a number of its standard breakers, some of a brand new design. One of these new instruments is constructed for railway voltages and shown in two sizes, the larger with a capacity of 1500 amperes. It is of the single pole, double break type, with finely laminated leaf contacts in the primary break, the auxiliary contacts being placed at the top of the instrument so that any arc from them cannot injure the rest of the apparatus. Besides the regular carbon break, the upwardly extended arms are fitted with auxiliary copper contacts which are intended to make a low resistance shunt around the main contact of laminated leaves and absolutely prevent any arc from forming at the latter point in case the carbons do not make good contact. This auxiliary copper break is the second to open, the carbons making the final opening of the circuit. The instrument is closed by a toggle joint, giving a pressure of some 800 lbs. to the main contact. Besides this is a breaker with a similar main contact, but designed only for underload release, and intended for use on storage battery charging circuits. Several other combinations of various releasing arrangements are shown in the booth, among others a breaker fitted for overload and low voltage, another for underload and push button control, and still another fitted with three releasing devices, one for the usual overload, the other for low voltage and the third for over voltage. This is designed for the charging of storage batteries at constant potential, and is designed to let go when the storage battery voltage rises to the fully charged value, or falls due to a rapid discharge. The company also shows some pieces of apparatus of lines in which they have not until recently been manufacturers. One of these is motor controllers and starting boxes, and the other field rheostats.

THE EXHIBIT OF THE COLUMBIA AUTOMOBILE COMPANY.

CLINGING VS. SLIPPING BELTS.—The Cling-Surface Manufacturing Company, Buffalo, N. Y., makes a unique exhibit illustrating forcibly the comparative action of belts with and without a treatment of Cling-Surface. The apparatus shown in the booth consists of three dynamo electric machines of Westinghouse manufacture, one running as a motor and driving, by means of belts, the other two which are used as genera-

Digitized by Google

tors. The latter machines are mounted on trucks allowing them freedom to roll in the direction of the belt tension, which is maintained and measured by means of spring balances. The belts are each 4 ins. in width and identical in all respects, except that one

THE TEST OF CLING-SURFACE.

of them has been treated with Cling-Surface and the other has not. The machine driven by the former supplies an electrically illuminated sign on the wall of the booth, reading "With Cling-Surface," and on the other machine is a similar sign, reading "Without Cling-Surface." The belt tension of both is maintained at the same value, viz., 115 lbs., by means of the balances, and it was intended to show the comparative slippage by the comparative drop in candle power of the lights on the two signs. The results obtained are, however, so much more satisfactory—considered from the standpoint of the company—than was expected, that the sign "With Cling-Surface" shines at full candle power with all the resistance in the field rheostat, while the other sign does not shine at all with all resistance cut out of the field rheostat. Further proof is readily obtainable on the part of those interested and willing to apply a little muscular effort to vary the belt tension. The Cling-Surface machine, when so far relieved of tension that the slack side of the belt falls and rubs the tight side, still maintains its load at the same candle power so far as the eye is able to determine, while the other machine can only be made to build up its voltage at all by a powerful effort applied to reinforce the initial tension of the spring balance.

AMERICAN ENGINE COMPANY, Bound Brook, N. J., exhibits a 50 kw. direct coupled generating set of which the engine is of the new "Duplex" compound design, which will be described later in these columns. The generator is of the company's own make and has no novelties in its construction except that the brush holders are of a new parallel motion type, the brushes being clamped in boxes which are radially pivoted to two arms, so arranged that the face of the brush remains parallel to the face of the commutator through a quite wide variation of the rise and fall.

THE BULLOCK ELECTRIC COMPANY, Cincinnati, Ohio, makes an extensive exhibit showing a number of its generators and motors, of which the largest machine is one of 65 h.p. capacity. One marine type generator is driven by a small Case engine and is fitted with two commutators, giving respectively 45 and 65 volts, the two being connected together and across one side of the Edison 220 volt three wire system, giving by various combinations of the circuits the following voltages: 45, 65, 110, 155 and 220. All of these pressures are carried to several motors controlled on the Bullock Company's multi-voltage system. Of these motors one is mounted in the headstock of a large lathe and another is direct geared to a shaper. They are shown in operation and controlled by Bullock controllers, which—the company takes considerable pride in announcing by means of placards—are of the magnetic blow out type. The exhibit also contains an overhead revolving globe lighted with appropriate illuminated signs.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Missouri, makes in its booth many transformations of electrical power, all on apparatus of its own manufacture. It takes 60 cycle alternating current which it steps up from 104 to 208 volts in its own transformers, passes it through instruments and switches on its own switchboard and feeds it to one of its 5 h. p. single-phase motors, which in turn is belted to a direct current generator. This again supplies power to motors direct coupled to ventilating fans.

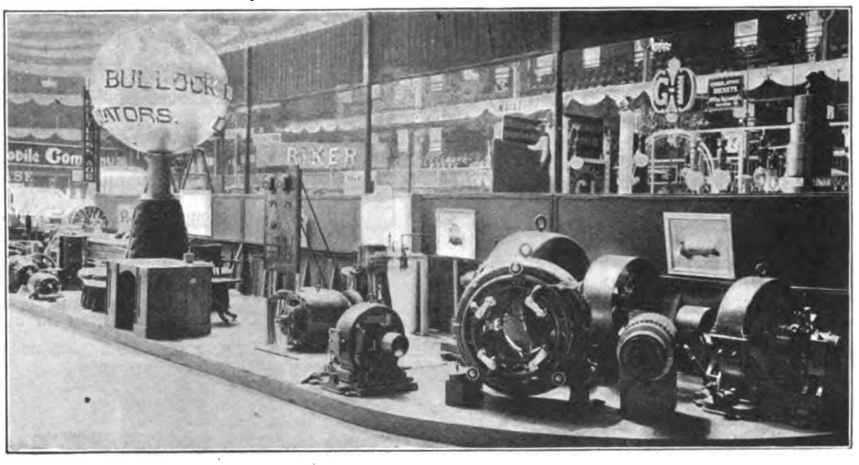
THE BOSSERT ELECTRIC CONSTRUCTION COMPANY, Utica, N. Y., makes an attractive showing of its enameled stamped steel junction and outlet boxes and handsomely decorated panel boards. Many special designs are shown, among them stamped brass fittings for marine work, special boxes for flush switches, etc., besides complete equipments of distribution panels with switching arrangements which the Bossert Company makes in addition to its steel boxes.

THE AMERICAN CIRCULAR LOOM COMPANY, Boston, shows in its booth a great cone coiled up of its flexible conduit, the advantages of which, besides those of its enameled steel piping, known as electroduct, are well brought out by the company's representatives.

THE ADAMS-BAGNALL ELECTRIC COMPANY, Cleveland, Ohio, makes a general exhibit of its various types of arc lamps which now include lamps for all methods of working commercially used. Besides the standard inclosed arc for direct or alternating 110 volt circuits and lamps designed to work in multiple or two in. series on 220 volt circuits, it shows a line of series inclosed arcs for constant current circuits, the practical use of which is illustrated by two full-sized curved-neck street lamp posts at the corners of the exhibit, each carrying an arc lamp, the two being supplied by a small Brush machine in a neighboring exhibit.

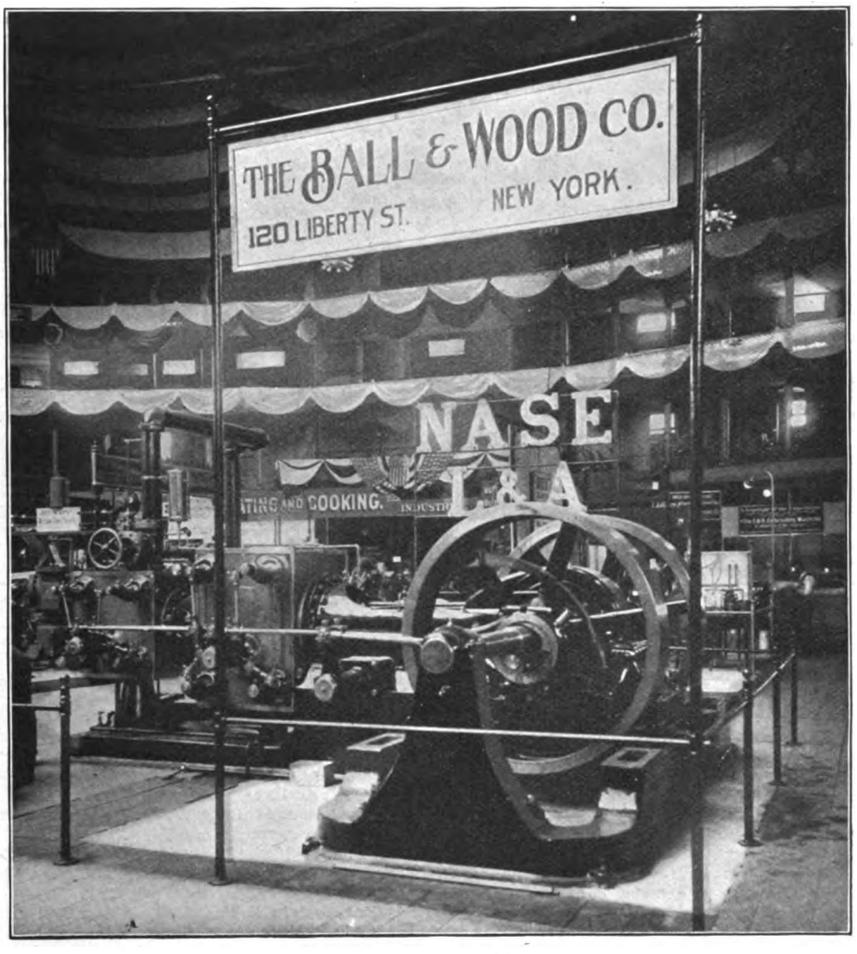
THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., have a number of their staff of instructors constantly on duty at their booth explaining the advantages of their system of instruction. To illustrate some of their arrangements there is shown a three-phase rotary converter feeding through open wiring, the circuits of which can be readily traced, three incandescent lights in the delta and three in the star grouping. To engineers acquainted only with direct current these arrangements of circuits are always a mystery, as it is difficult to understand how two currents can cult to understand how two currents can combine into one of the same strength, or how there can be the same difference of potential between any two of three wires.

THE BOOTH OF THE GENERAL INCANDESCENT ARC LIGHT COMPANY.



Digitized by Google

THE STIRLING COMPANY, New York City, shows one of its full-sized water tube boilers complete with the exception of the brick walls, illustrating most clearly the arrangement of the tubes, headers, grate surface and the deflecting fire brick partitions by which the hot gases are compelled to pursue a devious course between the tubes and thoroughly part with their heat before leaving the boiler.



THE WOODS MOTOR VEHICLE COMPANY, successor to the Fischer Equipment Company, of Chicago, was so rushed with construction work that its vehicles were somewhat delayed in arriving at the exhibition. They are an unusually handsome group for automobiles and consist of a runabout, a trap, a brake, a Stanhope and a hansom. The mechanical equipment of the vehicles exhibits no striking departures from what is coming to be standard automobile practice, viz., hub steering, single reduction gearing, rigid suspension on the running gear, solid tires, wooden-spoked wheels, etc. All but the runabout use two motors with band brakes on the armature shafts, the pinions on which mesh direct with gears on the main hubs. The runabout is a single motor machine with axle drive and a differential or jack-in-the-box inside the gear meshing with the motor pinion. The storage batteries used are either the American or the Willard.

THE CROCKER-WHEELER COMPANY, Ampere, N. J., makes a striking exhibit, the central feature of which is a very large field frame and brush holder ring, the external diameter of which is about 12 ft. Grouped around this are various sizes and types of its bipolar and multipolar machines, controllers, mill motors, etc., one odd machine having a vertical shaft, its armature rotating in a horizontal plane.

THE ORIENT ELECTRIC COMPANY, Youngstown, Ohio, makes an extensive exhibit of its standard lamps, which are of the single loop anchored filament type. In the line of special lamps it shows its long neck lamps for illuminated signs, 4 c. p. lamps and a 3 coil spiral high candle power type. In the booth there is also a complete line of miniature lamps, white and colored, made by Herman Boehm, of Youngstown, especially for the Orient Company.

THE BULLOCK ELECTRIC COMPANY'S APPARATUS.

A BALL & WOOD ENGINE.

THE H. B. CAMP COMPANY, Aultman, Ohio, shows a full-sized conduit of 16 ducts, 20 ft. in length, complete with brick manholes at the ends. The latter serve as piers between which the conduit supports its own weight as a beam, illustrating the strength and rigidity of the combination of cement and vitrified duct. Distributed along the top of the conduit are special forms, elbows, branches, curves, etc.

THE GENERAL INCANDESCENT ARC LIGHT COMPANY, New York City, occupies one of the two large triangular spaces at the Madison Avenue end of the Garden. Here it shows extensive lines of apparatus of its own construction, enclosed arc lamps, switches and switchboards, magnetic switches, outlet boxes, etc., as well as the product of the Paragon Fan Company, which it controls, and of the Wright Discount Meter Company and Chicago Rheostat Company, for whom the G. I. Company is the eastern agent. Two lines of discount meters are shown, one the familiar Wright instrument and the other the Hoyt discount meter, a mechanical instrument with working parts consisting of a solenoid operating on a plunger suspended over a pulley to which is attached a ratchet and a pawl to retain it in the position of maximum deflection, and a dash pot to prevent sudden jumps.

THE H. W. JOHNS MANUFACTURING COMPANY, New York, shows the new Noark fuse, the invention of Mr. Joseph Sachs. This is an enclosed fuse, using an alloy and enclosing powder carefully chosen to give a chemical absorption of the metal upon vaporization to prevent arcing. A detail of this fuse, which will immediately appeal to all who have used enclosed fuses, is an indicating device of the simplest character which shows at any time whether the fuse is burnt out or not. It consists simply of a fine wire of high resistance alloy just outside the enclosing tube of the fuse and connected from one terminal to the other. As soon as the fuse burns out, the current is thrown on this fine wire, which immediately vaporizes, giving by its absence indication that the fuse has been overloaded and has broken the circuit. The action of the fuse is strikingly illustrated in the booth of the H. W. Johns Company by short circuiting 15 ampere open fuses and 25 ampere Noark fuses straight across the Edison mains with 235 volts. The former give the usual report and flash, while the new type gives no visible or audible indication of the sudden strain upon it and the way in which it does its duty.

THE JOHN A. ROEBLING'S SONS COMPANY, New York City, makes a complete display of samples of its various copper products. In the way of special articles of interest are several large copper ingots, a case containing sections of the last laid Commercial cable, including the three different sizes, the shore ends, intermediate and deep sea sections, and a splice of the large three-phase 0000 underground cable which the Roebling Company has made for the Metro-

Digitized by Google

politan Street Railway Company for 6000 volt distribution. Besides these are paper insulated cables for telephone work and terminal heads for the same.

THE INCANDESCENT ELECTRIC LIGHT MANIPULATOR COMPANY, Boston, Mass., shows in practical operation its device for removing or cleaning, without the use of step ladders or staging, inaccessible incandescent lamps at considerable elevations. The value of the device is so easily appreciated upon seeing it working that the exhibit is proving a great source of sales for the company.

MACHADO & ROLLER, of New York, have one of the most complete exhibits in the building, consisting of Whitney electrical instruments of all sorts, ammeters, voltmeters, wattmeters, testing sets, etc.

THE BALL & WOOD COMPANY, New York City, shows one of its engines with rolling valves of the Corliss type. The engine shown is a tandem compound with a frame fitted for two dynamos, one direct-coupled to each end of the shaft. The latter machines are not in place. The exhibit attracts a great deal of attention on the part of engineers and engine users who appreciate the combination of the advantages of the Corliss valve and the shaft governor, which allows the economical features of low speed engines to be obtained in the high speed type.

THE COLUMBIA INCANDESCENT LAMP COMPANY, St. Louis, Mo., shows its products in the exhibit of Mr. R. B. Corey of New York. A show case at the front of the booth contains lamps in different stages of construction, showing the processes of manufacture. The filament is shown in a celluloid compound form in a vial, then as a raw filament and finally in its carbonized and treated state.

THE ELECTRICAL ENGINEER INSTITUTE OF CORRESPONDENCE INSTRUCTION, New York, occupies a booth where its instructors distribute literature and perform experiments, giving brief talks and lectures thereon to show the interest, scope and value of its courses of instruction.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., has an exhibit of graphite products for electrical and other uses, including resistance rods, boxes for baking lamp filaments, graphite dust, electrotyping graphite, belt-dressing and lead pencils of almost innumerable variety.

THE STANLEY ELECTRIC MANUFACTURING COMPANY, Pittsfield, Mass., has none of its heavy apparatus on show, but makes an elaborate exhibit of its various details, switchboard instruments, etc. Among other things it shows its high potential switch of the pole type for pressures of 10,000 volts and over, as well as its well-known shutter switches, rotating fuse switches, etc. A new instrument is a combined high potential switch and fuse, consisting of a handle carrying two knives, which may be completely removed from the clips buried in the board. A fuse running through the body of the handle connects these two knives. The company's latest designs of lightning arresters with double cones and a new form of line discharger are also shown. The latter consists of a series of glass tubes containing carbon shot, the whole about 5 ft. in length, in series with a spark gap. In the line of measuring instruments the company shows its well-known static voltmeters and ground detectors, and a new line of hot wire instruments in which it takes considerable pride. These are fitted with Foucault damping discs and are dead beat. They are made up both as voltmeters and ammeters in two forms, one for switchboard and the other for portable use.

AMONG OTHERS REPRESENTED are the following:

American Electric Novelty & Mfg. Co., New York City.
American Mutoscope Co., New York City.
American Pulley Co., Philadelphia, Pa.
American Vitrified Conduit Co., New York City.
American Min. & Dec. Lamp Co., New York City.
Allgemeine Elektricitats Gesellschaft, Berlin, Germany.
Buffalo Forge Co., Buffalo, N. Y.
Bryan-Marsh Co., New York City.
Cincinnati Shaper Co., Cincinnati, Ohio.
Dale Co., The, New York City.

## OBITUARY.

CAPT. ALFRED EPHRAIM HUNT, President and General Manager of the Pittsburgh Reduction Company, died in Philadelphia, April 26, at the age of 44 years. His death is supposed to have been indirectly due to malaria contracted in the recent war, Capt. Hunt having commanded a battery of the Pennsylvania Light Artillery in the Puerto Rican campaign. Capt. Hunt's engineering education was obtained at the Massachusetts Institute of Technology, from which he graduated in 1876, his course having been that of metallurgy and mining engineering. His business career commenced with the U. S. Geological Survey, from which he went to the Bay State Iron Works in South Boston, afterward doing some pioneer work in the opening up of the copper district in Northern Michigan. In 1888 Capt. Hunt organized the Pittsburgh Reduction Company to carry on the production of aluminum under the patents of Chas. M. Hall. The progressive work of this company is well known to electrical engineers and was largely due to Capt. Hunt's own personal enthusiasm, which hastened the introduction of aluminum for many uses in which its advantages would not otherwise have been so promptly and clearly recognized. Notable among these is the use of aluminum in place of copper for electrical conductors, particularly long distance transmission lines, which was, during the last year or two of Capt. Hunt's life, a particular hobby and was at the time of his death just coming into extended use, owing to the high price of copper. Capt. Hunt filled besides his position with the Pittsburgh Reduction Company the offices of Vice-President of the Georgia Beauxite & Mining Company, Vice-President and Treasurer of the Hunt Air Brake Company, Vice-Chairman and Treasurer of the Pittsburgh Testing Laboratory. He was also a member of the American Society of Mechanical Engineers and of the Iron and Steel Institute of Great Britain. His life's work will leave a lasting impression on both the engineering and financial departments of the metallurgical industries.

## PERSONALS.

MR. J. P. ORD, Second Vice President and Comptroller of the General Electric Company, has sailed for Europe, and expects to be away for about two months.

MR. H. H. BROOKS, General Manager of the American Circular Loom Company, of Boston, has returned home after a visit of several months to Bermuda.

DR. EDWARD HOPKINSON, the well-known English electrical engineer connected with the manufacturing establishment of Mather & Platt, and a brother of the late Dr. John Hopkinson, sailed from New York May 13th, after a visit of about one month in this country inspecting the latest electrical installations.

GEORGE G. WARD, Vice President and General Manager of the Commercial Cable Company, sailed May 17th for Cologne, where he will consult with the officials of the German Atlantic Telegraph Company on the subject of the new cable between Germany and the United States via the Azore Islands. The Commercial Cable Company's steamer "Brittania" has already started for the Azores to make soundings to determine the most suitable route.

KEMPSTER B. MILLER, recently with the International Correspondence Schools of Scranton, Pa., has accepted a position as engineer with the Kellogg Switchboard & Supply Company of Chicago. Mr. Miller's return to engineering work and designing will be a notable gain to independent telephony in general and the Kellogg Company in particular, as those who remember his work with the Western Telephone Construction Company will realize. Although a young man, Mr. Miller has made good and varied use of his time since graduating from the electrical engineering course of Cornell University in 1893, part of his knowledge of modern telephone practice being gained in the patent office and the rest in the positions above named. Mr. Miller is well known to readers of the American Electrician through the many contributions from his pen, and notably the serial now running, entitled "American Telephone Practice."

## TRADE PUBLICATIONS.

THE ROYAL ELECTRIC COMPANY, Peoria, Ill., has issued a bulletin on its inductor generators, described in a recent article in the American Electrician.

HELIOS.—The well-known publication of the Heine Safety Boiler Company, St. Louis, Mo., giving valuable information in regard to the whole question of steam generation, has made its appearance as revised for the eighth edition, that of 1899. The work is more than ever elaborate and handsomely illustrated.

THE NEW YORK SAFETY STEAM POWER COMPANY has published the third edition of its catalogue on the Worthington water tube sectional steam boiler, describing and illustrating various installations where this boiler is used. Its well known peculiarities of side or end firing, iron casing, grate surface under entire boiler, etc., are with other advantages well emphasized in the new catalogue.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS of Scranton, Pa., have issued a souvenir of their electrical exhibit, entitled "The New System of Education." The pamphlet gives a history of the schools, descriptions of the system of instruction and interior views of the headquarters of departments, interspersed with much valuable electrical information showing the thoroughness, accuracy and clearness of its lessons.

THE PITTSBURGH TRANSFORMER COMPANY has published a new catalogue of its type K transformer, giving more complete information as to the construction and performance of this instrument than is given in its first catalogue. The features of construction are given in such detail as to be of possible value to competitors, but the company has taken this course in order to thoroughly convince its customers that it is building a thoroughly well made and efficient transformer.

THE LUBRICATION OF GAS ENGINE CYLINDERS is a well recognized difficulty, owing to the extremely high temperatures attained by the burning fuel within them. The Jos. Dixon Crucible Company of Jersey City, N. J., makes up special graphite for such lubrication, which of course is not affected by heat nor burned, as is oil. Some letters describing the experience of users of this lubricant are given in a circular sent out by the Dixon Company, and speak well for the value of the material.

ENGINEERING AND POWER COMPANY, New York City, has published an illustrated catalogue of its steam specialties, chief of which is the Excelsior Indicator. This is a peculiarly compact and complete equipment with the Peerless aluminum reducing wheel attached ready for use, extra piston, two springs and cocks, boxwood scales, cord, cards, etc., etc., and is packed in one portable case. Besides these, the company handles planimeters, injectors, exhaust heads, damper regulators, lubricators, separators, etc. The General Manager of the company is Mr. A. C. Lippincott.

## BUSINESS NEWS.

THE MOUND TOOL AND SCRAPER COMPANY, St. Louis, Mo., is sending out a neat souvenir packing tool with all orders received during the month of May.

REMOVAL NOTICE.—The headquarters of the New York branch of the Ames Iron Works have been removed from 38 Cortlandt street to offices in the new Singer Building.

THE UNION BOILER TUBE CLEANER COMPANY, Pittsburgh, Pa., has begun an action in the United States Circuit Court to enjoin an alleged infringer from manufacturing, using or selling a certain device for cleaning the interior of boiler tubes.

MR. GERALD W. HART, formerly of the Hart & Hegeman Manufacturing Co., has severed his connection with that company, and is about to bring out a new line of goods. The first of this line is a two button push switch, and is put upon the market by the Hart Manufacturing Co., of Hartford, Conn.

A DYNAMO, ENGINE, BOILER, ETC., WANTED.—The Michigan Starch Company, Travers City, Michigan, announces that it has commenced the erection of a plant to consume 4,000 bushels of potatoes per day and is in the market for the power and lighting equipment therefor.

THE MOLONEY ELECTRIC COMPANY lately moved into more commodious quarters at the southwest corner of Second and Vine Streets, St. Louis, Mo., in order to obtain room for its growing business. The company reports an increasing number of orders and bright outlook for the future.

THE CHICAGO ADDRESS of the Buckeye Electric Company and the Jandus Electric Company, after May 1st, will be Room 1537 Monadnock Building. The increasing western demands for "Buckeye" incandescent and "Jandus" enclosed arc lamps necessitates the securing of larger shipping facilities.

THE CUTLER HAMMER MANUFACTURING COMPANY, Chicago, Ill., announces that during the month of April it has transacted the largest amount of business during the history of the concern. There has been a large demand for its crane controllers and also self starters for pumps and elevators.

THE WESTERN ELECTRIC COMPANY carries in stock a large supply of Samson spot cord. This cord is especially adapted for the suspension of arc lamps, for use as bell ropes in cars, and for trolley cord. Its smooth and pliable finish, combined with durability, lightness and strength, recommend it for many uses.

CONSOLIDATION OF MANUFACTURING INTERESTS IN BOSTON.—The Shawmut Fuse Wire Company, L. A. Chase & Company, the John P. Cushing Company and the Linton Manufacturing Company have combined their interests under the name of the Chase-Shawmut Company, with headquarters at 161-163 Fort Hill Square, Boston, Mass.

THE GARTON DANIELS COMPANY, Keokuk, Iowa, announces that since April 1st, the sales of Garton lightning arresters have been over double what they have been in the same period of any previous year. The company, in order to keep up its stock, has recently doubled its force of employees, and states that it will be able to meet any requirements for prompt shipments.

THE NATIONAL TELEPHONE COMPANY, formerly of Boston, Mass., has removed to St. Louis, Mo., where it has established a large factory at 1726 Glasgow avenue. The company is arranging to install a model plant at Belleville, Illinois, with a new multiple telephone system and gravity

Digitized by Google

drop switchboard. The exchange will have trunk line connections with the Kinloch system in St. Louis.

THE EXPANSION OF THE STROMBERG-CARLSON TELEPHONE COMPANY.—The Independent Telephone Company, with a capital stock of $100,000, has been incorporated to take up the manufacture of the well-known Stromberg-Carlson telephone apparatus. The management will be continued in the same hands, but the business will be continued on a larger scale with increased facilities for manufacture.

THE AMERICAN STOKER COMPANY, New York City, wishes to invite the attention of the attendants at the electric light convention to its equipment of American stokers in the Bay Ridge generating station of the Kings County Electric Light and Power Company, Brooklyn. Owing to the interest of this installation a large number of those attending the convention will undoubtedly visit it and will see among other things a model stoker installation.

PARTRICK, CARTER & WILKINS, Philadelphia, Pa., have found that the advantages of their automatic set-back annunciators have been so generally appreciated that the type has been extended to the following sizes: 4, 6, 8, 10, 12, 16 and 20 numbers. The favor with which this design has been met is undoubtedly due to the extreme simplicity of the mechanism, and consequent reliability of operation. The company states that it is doing an enormous business with these annunciators.

THE WARD LEONARD ELECTRIC COMPANY announces a reduction in the price of its Carpenter enamel field rheostats and theatre dimmers. This reduction is as much as 30% in most instances. Although the Ward Leonard Company has maintained low prices in the line of field rheostats and theatre dimmers, it has made such radical improvements in cost, due to new designs and production in very large quantity, that it can make the present large reduction in price and still make a fair manufacturing profit.

CROCKER-WHEELER ELECTRIC COMPANY takes a justifiable pride in such a distantly remote feat as the successful competition of the Pencoyd Iron Works for the famous Atbara Bridge contract. The success of the American bid against all British competition was due to the short time in which the mammoth work could be turned out, which in turn is alleged to be due to the electric distribution of power through the Pencoyd Company's works. The Crocker-Wheeler Company has always advocated such power distribution, and in fact constructed most of the apparatus used by the Pencoyd Company.

THE C. & C. ELECTRIC COMPANY, 143 Liberty street, New York, has decided to open its own office in Chicago, Mr. Martin J. Insull, the former sales agent for the Chicago territory, having severed his connection with the company and located in New York as Vice-President of the General Incandescent Arc Lamp Company. Mr. E. Sanderson, who has been representing the C. & C. Company in St. Louis for a year past, was appointed manager for the Chicago territory on May 1st. A suitable office location has not yet been secured, but it is quite probable that quarters will be found in the Monadnock Block.

THE ELECTRIC ARC LIGHT COMPANY has removed its general offices to large and commodious quarters in the Bowling Green Building, 11 Broadway, New York. It has largely increased its manufacturing facilities, and can promptly ship direct and alternating current enclosed arc lamps. W. C. Hubbard, General Manager, reports that the company is very busy at present, and has just closed some good orders with such concerns as W. & J. Sloane, the Ogden Goelet estate, the Central Railroad of New Jersey, the Palais Royal, Washington, D. C., Campbell & Smith, Herren Bros., John Daubs & Sons, Pittsburgh, Pa., etc.

THE MONTAUK MULTIPHASE CABLE COMPANY has arranged for an exhibit of its automatic thermostatic fire detective cables at the Paris exposition next year. The company will make a very complete exhibit of its wires in connection with all interior electrical adaptations, and it will undoubtedly be one of the electrical features of that Fair. The convention of municipal electricians to be held in September of this year at Wilmington, Del., promises to eclipse any previous convention in numbers and exhibits. The progress of municipal fire protection from its beginning down to the present will be illustrated by apparatus in vogue during the various stages of invention. The Montauk Multiphase Cable Company will have a complete display of its product in connection with all interior wiring.

SALES OF COCHRANE FEED WATER HEATERS AND SEPARATORS.—The Harrison Safety Boiler Works of Philadelphia, Pa., announces a remarkably long list of recent sales of Cochrane heaters and purifiers as well as separators. Of the former, the largest orders were for 5000 h. p. for the Delaware & Hudson Canal Company, Scranton, Pa., and 3000 h. p. each for the Midvale Steel Company and the Granite City (Ill.) Steel Works. Of separators two of the 14 in. size were ordered by the Coplay Cement Company, one 12 in. and two 4 in. by The Gladstone, Philadelphia, and one 12 in. by the Roxborough, Chestnut Hill & Norristown Railway, besides a multitude of the smaller sizes. Separators of the Cochrane type were also ordered by the United States Government for the captured steamships, Isla de Luzon, Don Juan de Austria, and Isla de Cuba.

DAMPER REGULATORS.—No steam plant with good draft to the boiler should be without a damper regulator. They return their cost many times in a short period. With a good regulator, the steam pressure on the boiler can be kept uniform, and uniform pressure means steady power. It also means longer life to the boiler, because the pressure on every part is continuous. Irregular steam with the accompanying changes in expansion and contraction causes leaky tubes and leaks around bolt heads and seams of plates, necessitating repairs, loss of time, etc., generally much more each year than the cost of a regulator. A good damper regulator prevents alternate forcing and checking, and in that way saves from 5 per cent. to 10 per cent. in fuel. Care should be taken to select one without complicated parts, so liable to give way, to get out of order, and cause trouble and expense. James L. Robertson & Sons, New York City, have had twenty years' experience, and can speak intelligently on this subject. They will be pleased to answer all inquiries.

ELECTRIC POWER IN ROLLING MILLS.—The exacting speed requirements of the different machines constituting a rolling mill to move the ingots, plates, rails, etc., through the mill with a minimum of delay and a maximum of time usefully employed on each machine, and to prevent any one machine from causing a blockade by reasons of the fact that it is running too slowly, are best met by the distribution of power to the various machines of the mill by means of electric motors. Realizing this fact, the National Iron & Steel Company of Mingo Junction, Ohio, recently contracted with the Westinghouse Electric and Manufacturing Company for the installation of an electric motor plant. The equipment is now completed, the generating plant consisting of two 150 kw. direct coupled dynamos, supplying current of 250 volts. The mills and offices are lighted and nine traveling cranes are supplied, besides a number of 20 h. p. motors driving separate sections of the mill, which consists of a set of continuous traveling rollers extending over a distance of 600 ft.

A VERY HIGH HONOR has been paid the Pelton Water Wheel Company recently in the award by the Franklin Institute of Pennsylvania of the Elliot Cresson Gold Medal—made as a just recognition of what is regarded by them as one of the most valuable products of American genius that has ever been produced. This award is accompanied by an elaborate and exhaustive report made by a committee of scientists appointed for the purpose, which traces the history and progress of water-wheel practice from the early centuries down to the most modern and improved methods. The report concludes with the following para-

A COMMUTATOR NECESSITY.

The Only Article that will Prevent Sparking.
Will keep the commutator in good condition and Prevent Cutting.
Absolutely will not gum the brushes.
It will put that high gloss on the Commutator you have so long sought for.

50c. per Stick. $5.00 per Dozen.

graph: "We have given this invention the fullest and most unbiased examination permissable within the time allowed us and within the compass of the literature at our command. We conclude that the Pelton Water Wheel possesses all the advantages of simplicity of construction, economy of installation and maintenance, adaptability to variable heads of water, transportability, a close and sensitive automatic regulation, and of high speed, which belong to other wheels of its class which have preceded it, but for efficiency and reliability it excells all others. We therefore deem the Pelton Water Wheel worthy of the Elliot Cresson Medal, and hereby recommend the award of same to the inventor."

MR. C. F. CROSELMIRE, whose platinum products are so extensively used in the electrical arts and industries, especially in the manufacturing of incandescent lamps, has recently received a $40,000 contract for electrical platinum attachments, to be used in preparing sea water for cleaning the streets of Havana, Cuba. The sea water is taken into capacious tanks and an electrical current is run through it by means of triangular pieces of metal, to which sheets of platinum, 1/1000 of an inch in thickness, are attached. The strong current of electricity run through the water breaks up the sodium chloride, giving free chlorine, which makes the water an excellent germicide, and with it the streets of Havana, and houses also, if necessary, will be flushed.

Mr. Croselmire spent very near all last year in the platinum mines of Russia and has made large business arrangements and purchases of crude platinum ore. During that time he has instituted processes in refining the metal whereby the percentage of platinum extracted from the ore is claimed to be greater than obtainable heretofore.

Mr. Croselmire will be pleased to quote prices and give information regarding platinum to any concern in the market for his goods.

THE WESTINGHOUSE MACHINE COMPANY'S EXTENSIONS.—Building operations are in active progress upon the extensions to the works of the Westinghouse Machine Company at East Pittsburg, Pa. The capacity of the foundry, machine and erecting shops will be doubled. The smithy and forge departments will be trebled in size. These extensions will make the main building 1200 feet in length, the width throughout being 230 feet. The warehouse and forge department will be nearly 700 feet in length. Large foreign as well as domestic orders for engines have necessitated these additions to the works. Messrs. Westinghouse, Church, Kerr & Company have recently contracted to supply several steam engines of very large horse-power. Among them are sixteen engines for the Third Avenue Railroad Company of New York City, to be of 4500 h. p. each, with a maximum capacity of 7000 h. p. each, also engines of equal capacity for the Bay Ridge power house of the Brooklyn Edison Company. These engines will be of the Corliss type, the first of this type built by the Westinghouse Machine Company. The demand for Westinghouse gas engines has greatly extended. These are being built in far larger sizes than hitherto. The Columbus Electric Company, Columbus, Ohio, has ordered a gas engine of 650 h. p. and another of 280 h. p. for direct connection to dynamos. The Consolidated Gas Company of Long Branch, N. J., has ordered a gas engine of 280 h. p. for electric work.

THE COPARTNERSHIP OF MR. CHAS. WIRT AND MR. IRVING B. SMITH, both of Philadelphia, under the firm name of Charles Wirt & Company, has been announced. They will continue the business, previously owned by Mr. Wirt, of manufacturing the Wirt dynamo brush and Wirt rheostat, articles too well known to require description here.

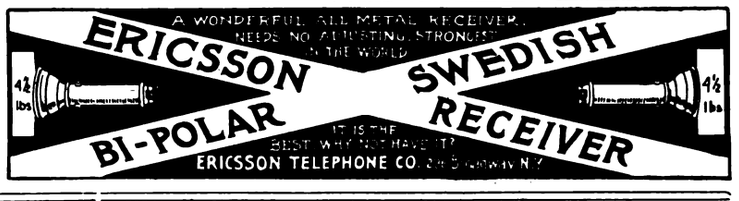
Mr. Charles Wirt entered the electrical business in the old Goerck Street Edison machine works, in New York City, in 1881. In 1882 Mr. Wirt was connected with the Western Edison Company of Chicago, and after leaving that connection returned to New York as chief electrician of the Bergman or New York Edison factory, at 17th Street and Avenue B. In 1889 Mr. Wirt was electrician of the standarzing bureau of the Edison Electric Light Company, with quarters at the Edison Laboratory, at Orange, N. J., where, in association with Mr. Kennelly and Mr. W. J. Jenks, specifications were formulated for the improvement of many parts of the incandescent system. In 1890 and up to the time of the failure of the Ansonia Electric Company of Chicago, Mr. Wirt was employed as electrician of that company and fathered the production of new designs and inventions, covering many lines of electric work, removing to Philadelphia soon after that time.

Mr. Irving B. Smith received his earlier education at Cornell University in the course of electrical engineering. Until forming the present partnership he has been connected with the firm of Green and Company, Inc., as chief of their electrical department. He has been in their employ since 1892, and as their electrical engineer has gained a considerable and well deserved reputation as a designer and constructor of scientific and commercial electrical instruments.

The new firm has been fortunate in securing additional room without change of address, by taking another floor in the manufacturing building, 1028 Filbert Street, an admirable location, within the business center of Philadelphia, close to the Reading Terminal Railroad Station, and well equipped for the line of manufacturing which they have chosen.

THE GROWTH AND DEVELOPMENT OF THE ELECTRICAL SUPPLY BUSINESS IN THE SOUTHWEST.—Ten years ago there were few electrical supply houses of any importance in the United States. Ten years has, however, caused a remarkable change in this branch of business speculation.

Only a few years ago the electrical, as well as numerous other forms of mercantile business, was transacted mostly in the East, in such cities as New York, Boston and Philadelphia. The demand, however, for this class of goods in the Middle and Western States increased so rapidly that the electrical supply houses were soon located in large numbers in central and Western cities. Chicago, St. Louis, Cincinnati, Detroit and other large cities were the sites of a rapid development in the electrical enterprise.



Six years ago the Western Electrical Supply Company of St. Louis, Mo., was organized for the purpose of transacting a general electrical supply business. This company was started at this time in a very small way, occupying at that time a floor area of only about one thousand square feet. Strict at-

tention to business, however, combined with energetic efforts to establish a business on a substantial basis and with a determination to carry a line of goods in accordance with the requirements of their customers, was followed by constantly adding to its line of agencies all high grade goods and maintaining the standard of all such goods as well as increasing the variety and the quantity from year to year.

The Western Electrical Supply Company at the present time has salesmen covering the Central, Western and Southwestern States thoroughly, and has become a well known factor throughout the entire country. It represents none but high grade manufacturers, and aims to supply the trade with goods that are excelled by none and equal to the best of anything in the market.

It has several lines of goods made especially for its own sale and directly under its general supervision, which practically establishes it as a manufacturer as well as a dealer. It is now located at 10 and 12 North Ninth Street, where it occupies an entire building, with a floor space at the present time of about 55,000 feet, and is very much crowded for room even in this spacious building.

The officers of this company are Mr. H. K. Gilman, President and Treasurer, and Mr. R. V. Scudder, General Manager, both of whom have long had experience in the electrical business.

The business of the company is divided into six large departments comprising the following: Electrical apparatus, lighting supplies, electric and combination fixtures, electric railway supplies, house goods supplies and telephone supplies.

Among some of the largest manufacturers whom it represents are the John A. Roebling's Sons Company, Trenton, N. J.; the Indiana Rubber and Insulated Wire Company, Jonesboro, Ind.; the Warren Electric and Manufacturing Company, Sandusky, Ohio; the Eddy Electric Manufacturing Company, Windsor, Conn.; the Ohio Brass Company, Mansfield, O.; the Western Telephone Construction Company, Chicago, Ill.; the Adams Bagnall Electric Company, Cleveland, O..

There are numerous other manufacturers of importance whom this house represents on fan motors, small power motors, switches and numerous other supplies of every description.

The Western Electrical Supply Company demonstrates quite fully its capacity for supplying and caring for the trade in its mammoth 750-page general catalogue. It also issues separate catalogues for its various departments. It is represented at the electrical convention in New York by President H. K. Gilman, who will be pleased to meet any of its friends and patrons, and, in fact, the entire electrical fraternity, such as is represented on this occasion.

## THE STREET RAILWAY SYSTEM OF KINGSTON, JAMAICA.

### AN EXAMPLE OF HIGH GRADE HYDRAULIC AND ELECTRIC ENGINEERING IN THE WEST INDIES.

BY HENRY E. RAYMOND.

It is not usual to find in cities of 50,000 inhabitants a street railway system built according to the latest improvements in every detail. This, however, is the case with the city of Kingston, Jamaica, which is perhaps one of the last places where one would look for such a perfect system. The streets, until very recently, were practically unpaved, and were drained by surface sewers, many of them being "crowned upside down," the drains being down the center of the street. The West India Electric Company, Ltd., an organization of Montreal capital, obtained the franchise to build and operate an extensive street railway, and also territorial rights to do the lighting. Starting work a few months after obtaining the franchise, they absorbed the old car company, which ran a service of very old mule cars, and have now completed works involving the expenditure of about $1,000,000.

The tracks are of 90-lb. steel girder rails, running through the city, and 60-lb. rails running through the country. The track is laid according to some very recent specifications, a somewhat similar construction being used in Buffalo, N. Y., U. S. A. The rails are laid on steel channel bar ties, 7 ins. wide, and are bedded in 8 ins. of concrete, which at the rail is raised so as to enclose it half way up the web. There are six miles of double track and 13 miles of single track.

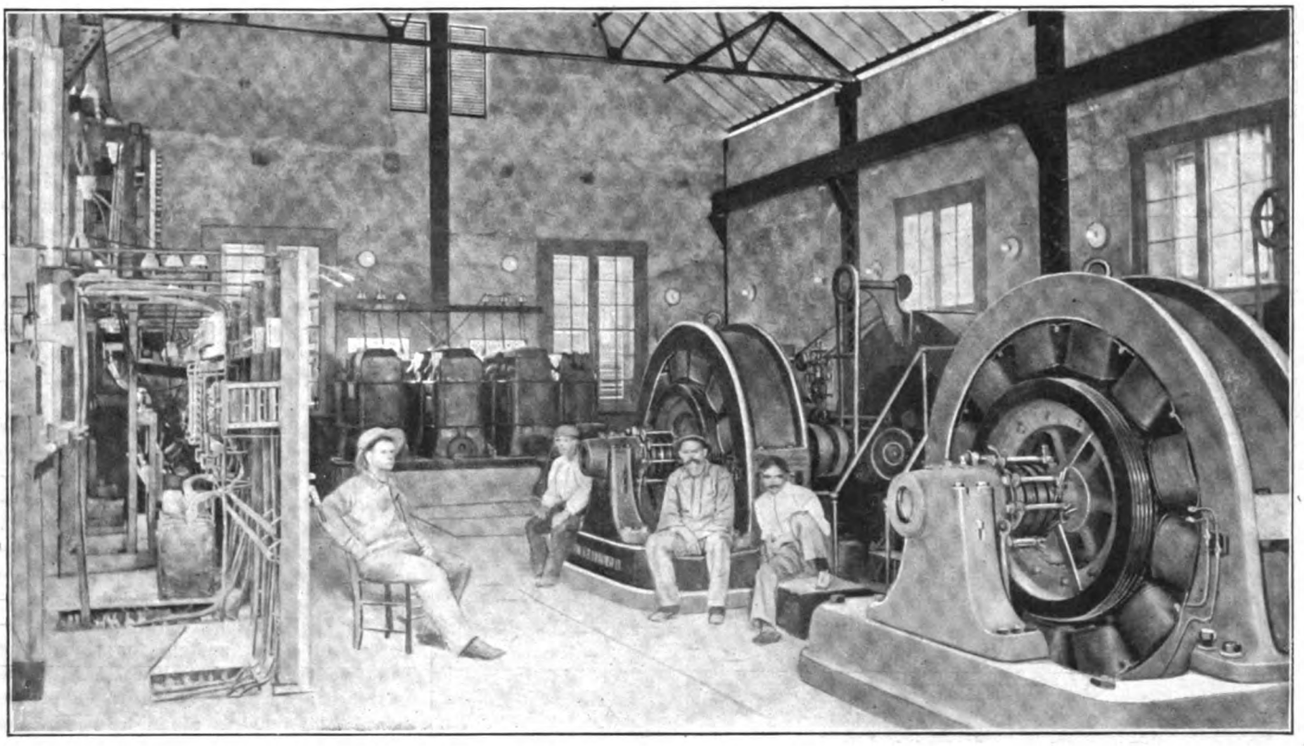

FIG. 1.—THE INTERIOR OF THE GENERATING STATION OF THE WEST INDIA ELECTRIC COMPANY, LTD.

Seventeen cars are run daily, the present equipment being 20 open cars, 6 trailers, or "market cars" (so called because they are run to accommodate the country people coming to the markets), and 2 sprinkling cars. The business done is large, and the system bids fair to pay well. Less than two weeks after starting it was evident that more cars were needed.

It was orignally the intention to work the line from a regular steam power plant, but it was soon evident that the cost of coal would be too great a percentage of the earnings, and prospecting was at once begun to find a suitable water power. The services of the Stilwell-Bierce and Smith-Vaile Company were enlisted, and this company sent its hydraulic engineer, Mr. R. H. Cooper, who went over the conditions and recommended the development of a power on the Rio Colre, 21 miles from Kingston. The same company then took the contract to design and install the power plant, complete, from its own designs, taking the river as it was and turning over a finished installation.

On the Island of Jamaica—as in all British Colonies—the "King's Highway" is of the first importance, and has to be protected under all circumstances. It happens here that the government road runs along the river bank at a height just sufficient to keep it above ordinary high water. A dam of sufficient height to give a practical head would have caused the flooding of several miles of road. It was found, however, that the location which was finally chosen was such that a dam 9 ft. high could be

Digitized by Google

built, causing no inundation of the highway, except at extremely high water, and the water could be piped to a lower point down stream, where a head of 54 feet is obtained.

The dam is built of concrete and is 90 ft. wide, with cross section, as shown in Fig. 4. The flash boards are held in columns built up of Z bars, and extend 3 ft. above the dam. At the left of the dam is the skimming basin (see Fig. 7), from which the pipe intakes. The intake of the pipe is 10 ft. in diameter, narrowing to a diameter of 8 ft., which is its size throughout its length. It extends from the dam 6,240 ft. to the power house, and is built of ¼-in. steel riveted in 6 ft. sections.

It may not be out of place here to state that in cubic contents it is one of the largest (if not the largest) pipe lines in the world, and was constructed with untrained native labor, there being only two white men superintending the construction.

The power house is built entirely of steel and concrete, and is carried on foundations from 10 ft. to 16 ft. deep. The building stands directly in the bed of the river, and must needs be sufficiently strong, not only to satisfactorily hold the machinery, but also to resist the freshets, which come down, like all tropical floods, with tremendous force. The building is 70 ft. long and 36 ft. wide, and is built with latticed columns, and I beam girders throughout. The turbines, two of which are at present installed, are on the east side of the building, with room to the south for a third unit. The wheels are regular Stilwell-Bierce and Smith-Vaile Company's twin turbines, and are designed to develop 400 h. p. at 40 r. p. m. The generators, in common with all of the electrical equipment, are of General Electric manufacture. They are of the most recent construction and are designated as A. T. 12-300-400, that is, they are 3-phase stationary field, 12-pole, 300 kw. 550-volt machines, designed to be used with step-up transformers, which are of the air-blast type. Each generator feeds three transformers, which are connected with both secondary and primary in delta.

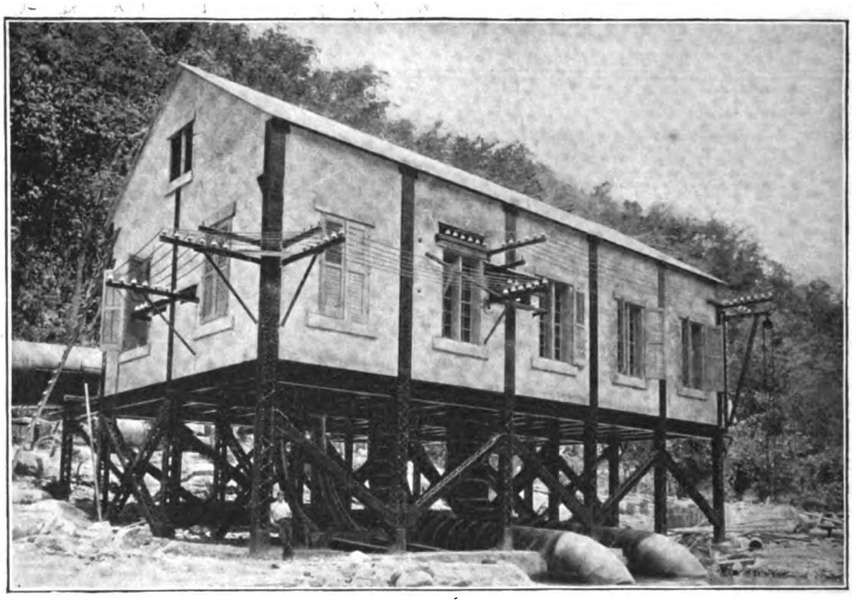

FIG. 2.—THE POWER HOUSE, SHOWING DRAFT TUBES AND UNDER FRAMING.

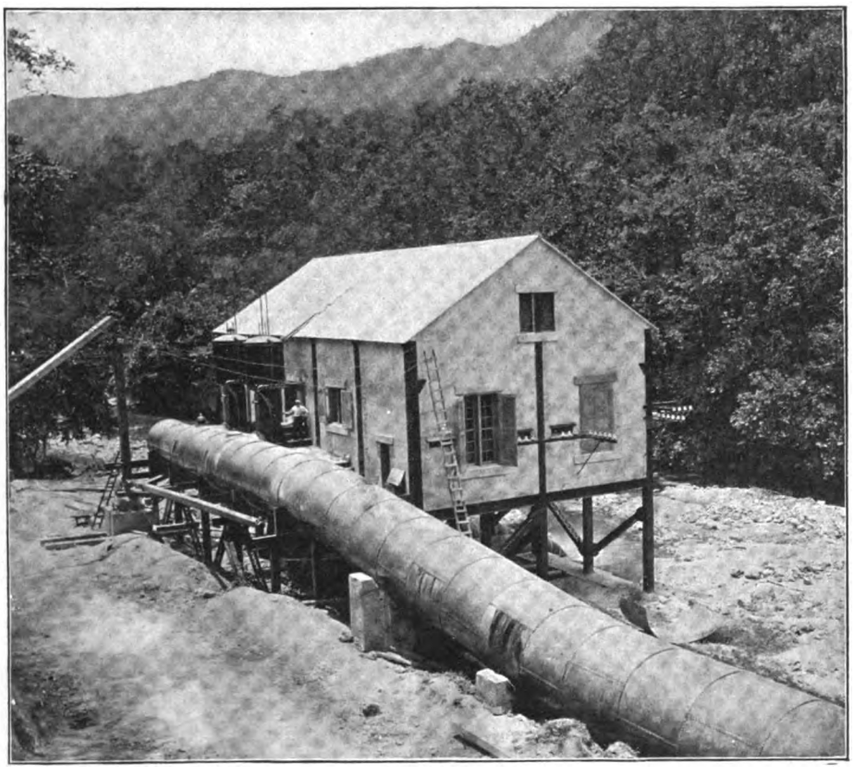

FIG. 3.—THE POWER HOUSE, SHOWING PIPE LINE, RECEIVER AND GATES.

The foundations for these transformers consist of concrete walls 12 ins. thick and 30 ins. high, with a row of concrete piers down the middle. The air chamber is made by flooring the top of this foundation with 2-inx12-in. pitch pine plank. The low-tension connections are made in the air chamber, and are led through porcelain tubes into conduits in which they are carried to the switchboard. The high-tension connections are made overhead, and are led out of the building through 12-in.x36-in. openings in the wall, to cross arms, on which they are carried around the building to another set of openings, through which they are brought to the switchboard. The blowers are set on the floor directly at the west end of the air chamber, the motors being raised on concrete piers 12 ins. high.

The switchboard consists of eight blue Vermont marble panels, two blank ones being left for the third unit. The high-tension panels for each set of transformers contain only the high-tension switches, which are of triple-pole, double-throw, oil-break form, the handle alone being on the front of the board. An auxiliary panel carries a triple-pole, single-throw, oil-break switch for paralleling the two transmission lines. All these switches are placed on the back of the board, the handles alone being on the front. The auxiliary panel is provided, also, with two astatic ground detectors, and six ammeters, connected to show the current in each phase. These ammeters are directly across the secondaries of current transformers, thus avoiding all high tension in the front of the board. The generator panels are each equipped with 3 single-pole, quick-break switches, and the necessary meters, field switches and synchronizing lamps. The exciter panels are equipped with the necessary switches and meters for two exciters, which operate at 110 volts. These exciters are 4-pole, moderate speed machines of 25 kw. capacity, each coupled

Digitized by Google

directly to a single turbine 9 ins. in diameter.

The lightning arresters in this plant are placed on a frame made of 4-in.x6-in. pitch pine, and mounted on struts so as to bring them about 30 ins. from the face of the wall; 1-in. bolts, extending entirely through the frame work, struts and wall, hold them in place. This construction leaves 18 ins. clear behind the panels, in which space the wires to the transmission line are carried.

The low-tension wires are all carried in conduits beneath the floor, and rise only at the machines, switchboard and transformers. The high-tension wires are all carried on porcelain line insulators on wooden cross arms. From the transformer primaries they are run outside, through the holes before mentioned, and are carried on long pitch pine cross arms, around to the middle of the west wall, through which they are carried directly to the high-tension switches. There are two sets of bus wires, to which the two transmission lines are connected.

The power house is equipped with a jib crane of 5 tons capacity, which is outside the door, and a traveling crane of equal capacity. In order to avoid interfering with this crane, the high-tension wires are all run outside the building as described.

The transmission line is carried on 2 cross arms, on tubular steel poles, 4 wires being on the upper and 2 on the outer ends of the lower arm. Two telephone wires are carried on the lower cross arms next to the pole. There are 6 transpositions on the line, making 2 complete turns in the entire length. The transpositions are so made that the sets of 3 wires each spiral in opposite directions. The transmission line enters the sub-station in Kingston through a large, square opening in the rear gable.

The sub-station is built of brick, with a truss roof, and galvanized iron roofing. There is also a section of monitor roof for ventilation. There are at present 2 rotary converters, 6-pole machines, of 200 kw. capacity each. The converters are designed to run at 550 volts on the d. c.

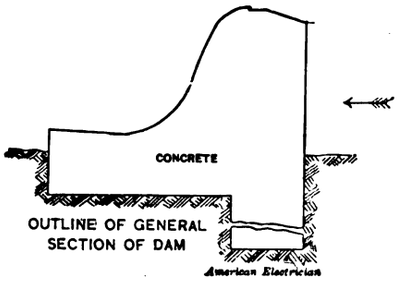

FIG. 4.—A CROSS SECTION OF THE DAM.

end. The system being 40-cycle, and the rotaries 6-pole, they run 800 r. p. m. In spite of the high peripheral speed they run very smoothly, and very coolly. They are self-excited, compound-wound, the compounding being done exactly as with a similar direct-current generator, with the German silver shunt across the series field.

When starting as a. c. motors there is, of course, a transformer action tending to induce a considerable potential difference across the field terminals. In order to avoid extremely high voltage across the shunt winding, the field coils are split up into 3 pairs of two in series, and are not connected until the machine is running synchronously. To avoid a short-circuited secondary effect through the series coils and the German silver shunt, a switch is placed in series with the shunt.

The step-down transformers are placed on a wooden air chamber, which, in turn, is placed over a duct or pit, through which the high-tension wires run. The sides of the air chamber are of 6-in.x 16-in. pitch pine, the bottom and top of 2-in.x12-in. pitch pine. The center line of weight is carried on short, wooden columns, supported by 3-in. steel rails placed across the top of the pit. The pit is 7 ft. wide and 4 ft. deep.

The low-tension cables run directly through a conduit to the switchboard.

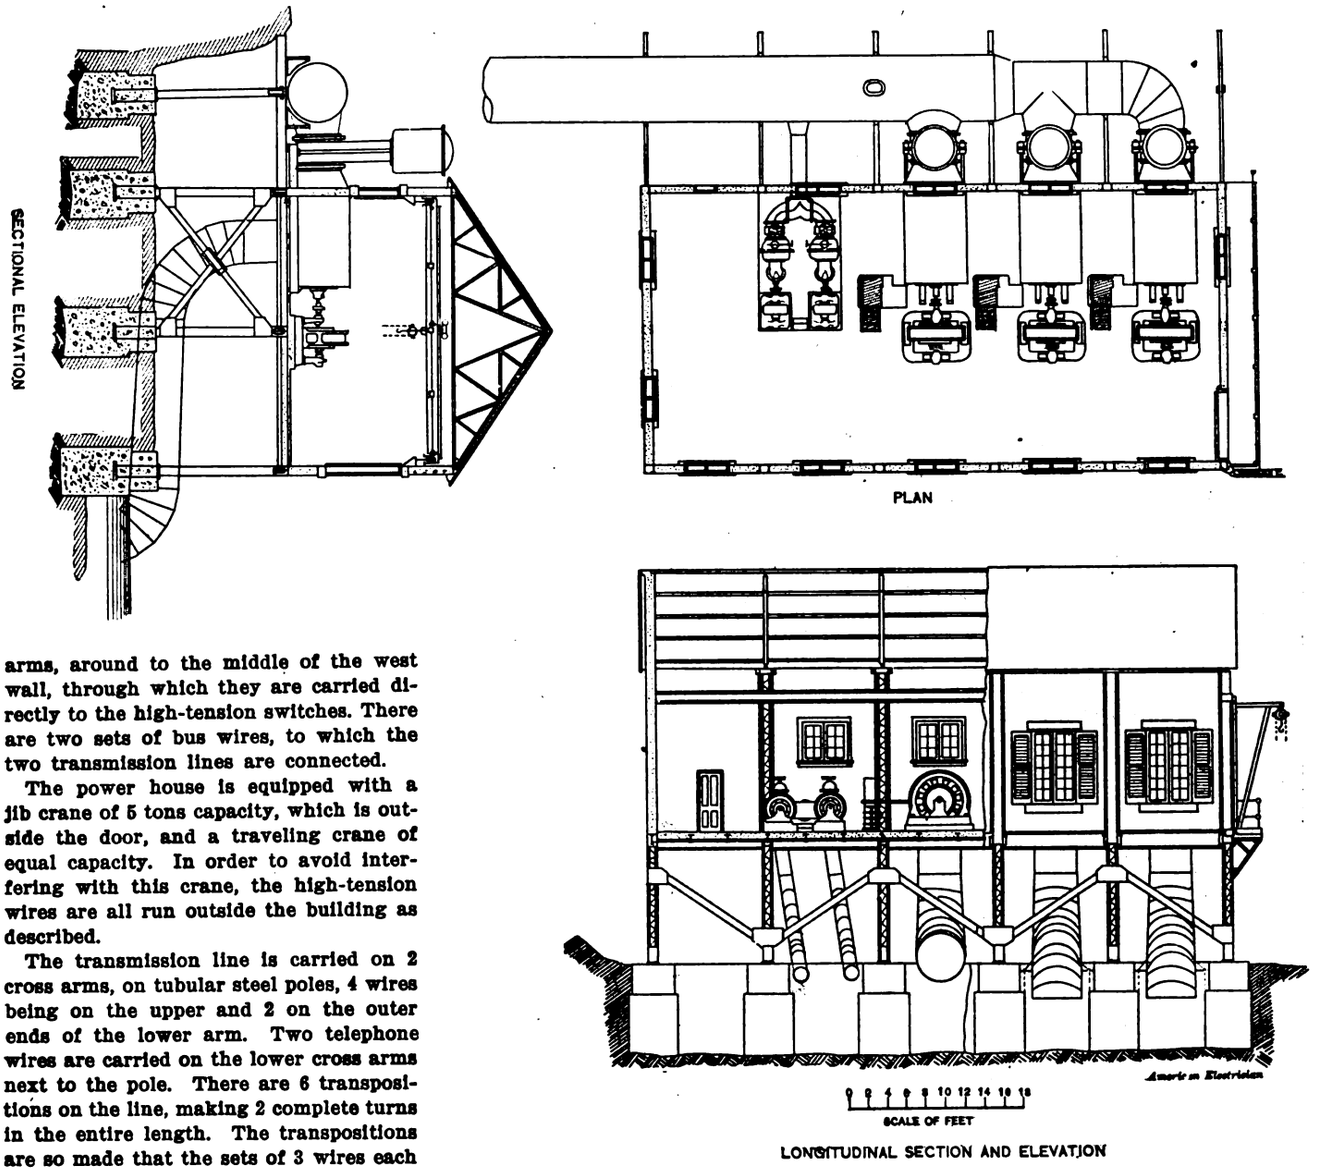

FIG. 5.—PLAN AND ELEVATIONS OF POWER HOUSE.

Digitized by Google

The primary leads are carried to a set of bus wires, carried on short cross arms on posts set between the 2 rows of transformers. These bus wires lead through the current transformers for the high-tension ammeters, to the oil-break switches. The wires leading to the transmission line are connected directly to the high-tension bus wires on the boards and pass directly down into the pit. Through the pit they are supported on line insulators on cross arms set in concrete at each end. At the opposite end of the pit they rise, and pass up the wall behind the lightning arresters to 2 sets of cross arms, on which they are carried to the openings, through which the line enters.

The blowers and their motors stand on a wooden platform beyond the end of the air chamber, and are carried on the steel rails which cross the high-tension wire pit. The lightning arresters are on a pitch pine frame, similar to the one in the power house, but supported on corbels set into the brick wall. They are of the standard, short-gap type, and are connected 24 gaps to ground.

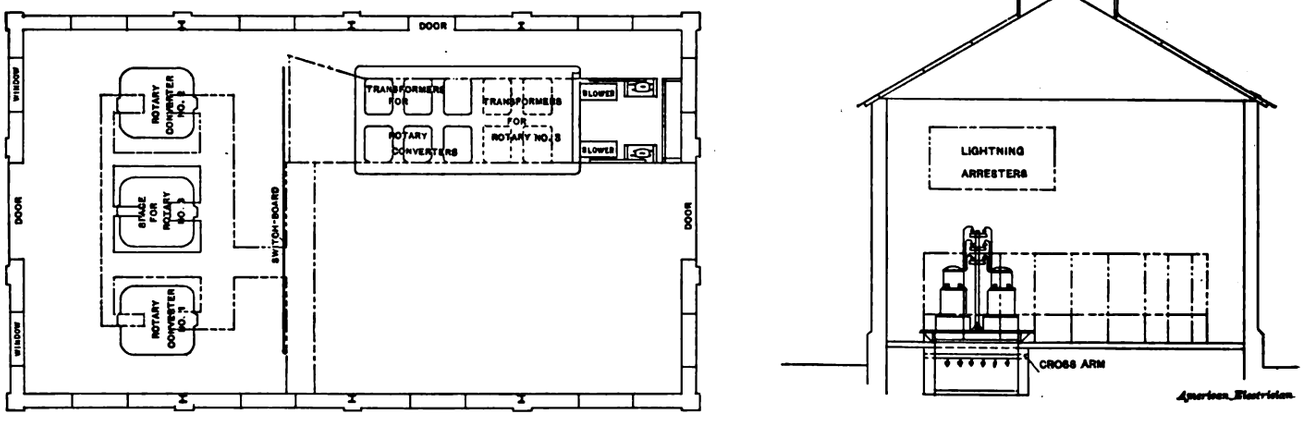

FIG. 6.—PLAN AND ELEVATION OF SUB-STATION.

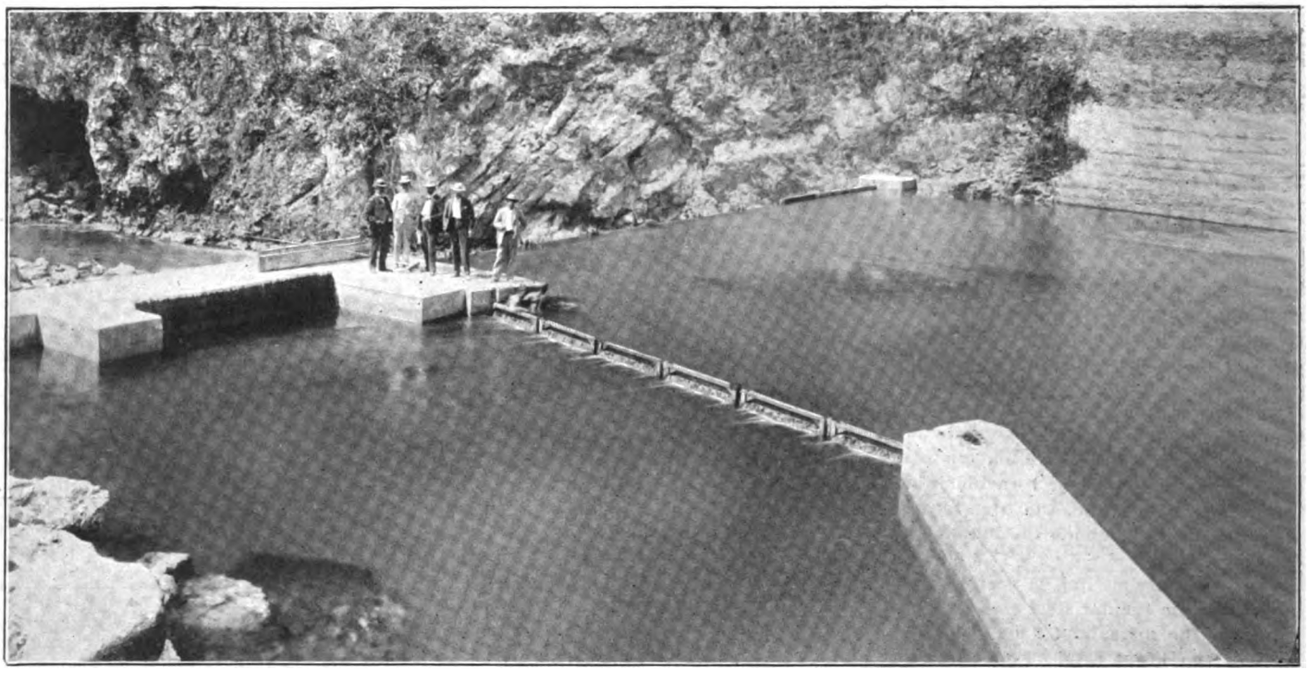
The switchboard is of blue Vermont marble and consists of 9 panels, there being three for high-tension connections similar to those in the power house, one blank panel, two low-tension panels for the a. c. end of the rotaries, two standard railway panels for the direct-current side and one feeder-panel for four feeders.

The step-up transformers step up to 14,000 volts, at which pressure the power is transmitted to Kingston, where it is stepped down to 345 volts for the rotaries. The relative field excitations are adjusted so that at about ¾ load the rotaries will operate non-inductively. The rotaries may be started from rest, from either the a. c. or the d. c. side. The usual custom is, however, to start the generator and rotary from no cycles, and with a full field on the generator. It was found that with weak fields on the generator and rapid acceleration of speed the rotary will pulsate in and out of step, frequently reversing the polarity of the d. c. voltage. This is avoided by bringing the generator up to speed slowly, and keeping a strong field on the same. The normal non-inductive, full load alternating current for the rotary is 340 amperes, but only 200 amperes are necessary to start it from rest, and bring it up to speed as an induction motor.

The switchboards are provided with switches and a starting rheostat, so that either rotary may be brought up to speed



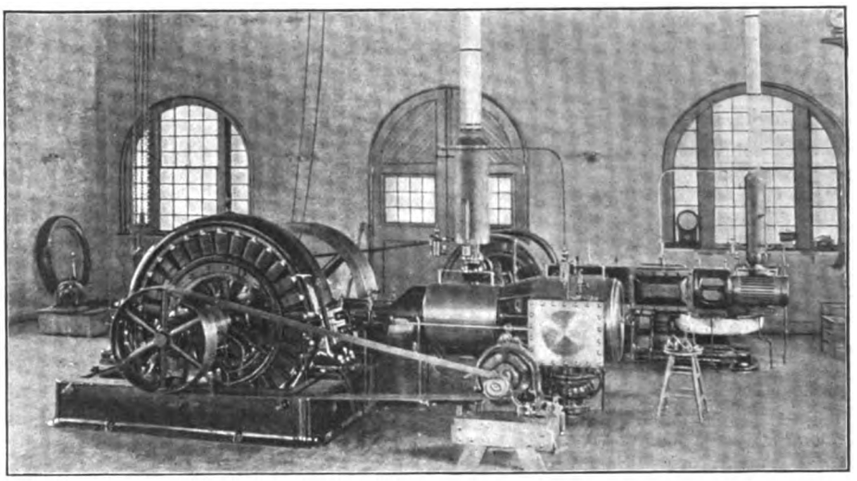


FIG. 7.—A VIEW OF THE DAM AND SKIMMING BASIN.

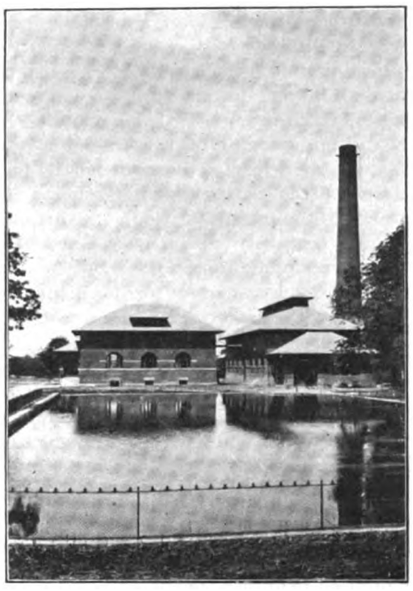
Digitized by Google

as a direct-current motor, and, after synchronizing, be thrown in parallel on the a. c. end with the other rotary.

The general design of the plant is such that either generator unit can be operated on either transmission line, and either rotary unit the same. For its size it is one of the best equipped and best finished plants in existence; in fact, the entire system, including the dam, power plants, car sheds, track, and overhead work, is of the most substantial construction. The power plant started operation on the 1st of April, and developed a capacity, both in water power and electrical equipment which exceeded to a considerable extent, not only the guarantee, but even what was expected of it.

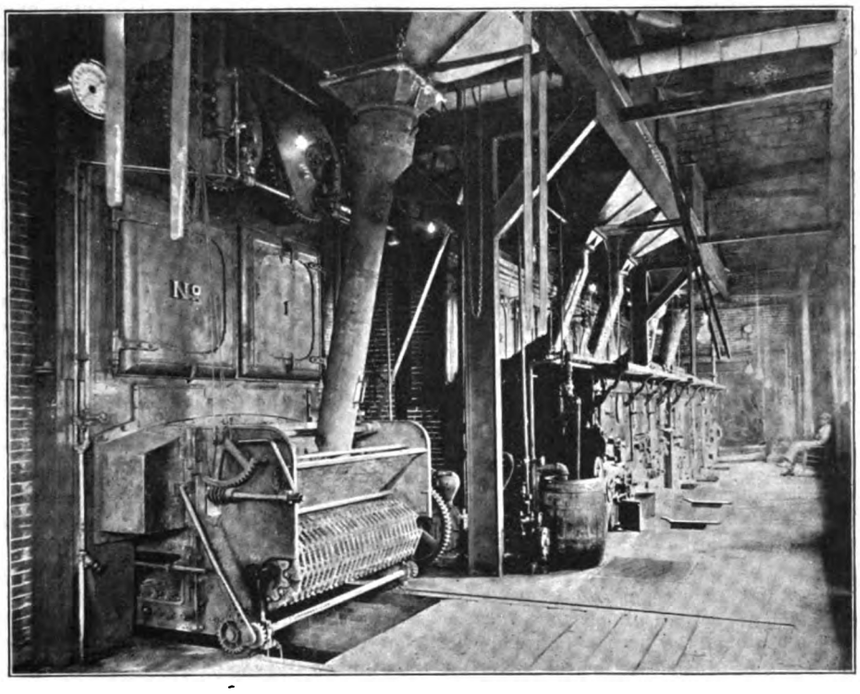


THE DIRECT COUPLED ALTERNATOR.

## THE POWER STATION OF THE OHIO STATE UNIVERSITY.

One of the most modern and complete systems to be found in the country for supplying heat and power from a central station to a group of large and widely separated buildings is that installed at the above institution in Columbus, Ohio. There are ten buildings in the group, having a total heating surface of 41,000 square feet. On the lighting circuit are 2200 incandescent and 11 arc lights, and on the power circuit 17 two-phase Westinghouse motors, from 1 to 30 horse-power. These motors are used for driving the ventilating fans in connection with the heating system, as well as power blowers, shop tools, electrical laboratory apparatus and the hay cutters, threshing and other machines in the dairy and farming department.

A 10-in. steam pipe, with suitable pressure regulator and with the proper reduction to suit the distance and size of the different buildings, leads out from the power station and is supported along the side of a brick tunnel nearly six feet square, and having a total length of 4100 feet, the longest distance to any single building being 2500 feet. Beneath the steam pipe is a general return pipe, in which the water of condensation gravitates to the hot well in the boiler house, as the grade is about 1 in 900. The wires for the light and power currents are also supported along one side of the tunnel, those for the high tension current being lead encased. The heating system embraces the Paul, Sturtevant, Buffalo and direct methods.



The steam generating equipment consits of five boilers, all of the Babcock and Wilcox make. Four of them are equipped with the Murphy smokeless furnaces, manufactured by the Murphy Iron Works, Detroit, Mich., while the one shown in the foreground of the view has the Babcock chain grate.

The coal is carried by conveyors to hoppers located above and in front of the boilers, from which it is delivered by chutes to the furnaces. The ashes are removed by an endless screw conveyor, and then elevated to bins from which the contents will readily gravitate through chutes into wagons placed outside the boiler house. The coal handling machinery is driven by a small vertical engine located in the boiler room, which, with all the coal equipment, was installed by the Jeffrey Manufacturing Company of Columbus.

The water for condensing purposes is taken from the end of the reservoir farthest from the station, and discharged into the other end through a five-inch pipe. This reservoir is designed for fire purposes, as well as for condensing, and is 90 ft. x 200 ft. and five feet in depth, and when filled contains 500,000 gallons. It is interesting to note that during the coldest weather of the past winter no part of this reservoir was frozen over. The water is pumped by a pneumatic system from a well beside a river 1700 feet from the reservoir, and 40 feet below its level.

The power equipment consists of two tandem compound engines. One is of the

THE BOILER ROOM, SHOWING MECHANICAL STOKERS.

Digitized by Google

McEwen manufacture, and drives by a belt a 60 kw. 2-phase Westinghouse generator. The other is a Watertown engine, which runs at 240 r. p. m. and is direct coupled to a 125 kw. generator of the same make and character. The auxiliary equipment consists of Sweets direct separators connected above the throttles, a 200 h. p. Wheeler surface condenser and a Hine eliminator, connected with a Bundy trap, which are located in the basement. The station is in charge of Mr. W. C. McCracken, Chief Engineer.

The results that were obtained in tests carefully carried out by Prof. E. A. Hitchcock upon both the stokers and the Watertown direct coupled engine may be summarized as follows: The fuel used was Hocking & Thacker pea coal, the latter having a considerably greater calorific value as shown by a Mahler calorimeter and giving the higher figures mentioned below. The water apparently evaporated per pound of coal varied from 5.76 lbs. to 8.3 lbs., while the equivalent vaporization from and at 212 degrees per pound of dry combustible varied from 9.52 to 11 lbs.

The engine was given three runs under three different loads with a steam pressure of about 100 lbs. and a vacuum of about 21 in., the results being briefly as follows:

| | | | |
|---|---|---|---|
| Indicated h.p..... ..... | 142 | 125 | 92 |
| Electrical h.p..... | 126 | 107 | 73 |

## THE MANUFACTURE OF GRAPHITE.

In a paper presented by Mr. E. G. Acheson before the Franklin Institute an account was given of the process of manufacturing graphite to be applied commercially at Niagara Falls. From this paper the following paragraphs have been extracted:

Very early in my experiments on the manufacture of carborundum, I noticed that graphite occasionally formed in the portion of the furnace charge lying next to the cylinder or granular amorphous carbon, which passed through the center of the furnace, and which became heated to an extremely high temperature by the passage of a heavy electric current, and around which the charge was placed to receive the heat necessary for the formation of carborundum. Also that when ordinary bituminous coal coke was used to form the core, quite a large amount of it was converted into graphite, whereas, when petroleum coke was used, very little of it was made graphitic.

By a careful study of these formations it was found that the graphite formed outside of and surrounding the core was produced by the decomposition of the carborundum, which is, chemically, a carbide of silicon, and, by induction from a number of known facts, that that formed within the core was also produced from a similar decomposition of carbides, which were created by the chemical union of the carbon of the core with its contained impurities.

As the result of my investigations and deductions, I think the only commercial way to make graphite is by breaking up a carbide by the action of heat. The carbon should be freed from chemical combination by what might be termed the evaporation of its associated elementary substances. I have secured patents covering this method, and these have been made the basis for the organization of an incorporated company, bearing the name "Acheson Graphite Company." The company has now under way the erection of works at Niagara Falls, where the necessary electric current will be obtained from the Niagara Falls Power Company.

Several distinct forms of the product will be produced. One consists of forms or articles, made out of amorphous carbon, with the desired amount of impurity added thereto, which will afterwards be heated in an electric furnace and converted, more or less, into graphite. I have been carrying on this line of manufacture for a year or more, using the furnaces of the Carborundum Company to produce the graphitization, the articles having first been made by the arc-light carbon manufacturers. Over 200,000 carbon electrodes, measuring 15 inches in length, with about 1 inch cross-sectional area, were made for use in the Castner alkali process, nearly one-half of them having been shipped to Europe, to be used for this work in England and Germany. The life or efficiency of these graphitized electrodes is many times that of the same electrodes ungraphitized. I have also graphitized some tons of carbon plates, to be used in making dynamo and motor brushes, and a large variety of odd forms and sizes for divers purposes.

Another product—the one which will probably be of greatest importance—is an intimate mixture of pure amorphous carbon and graphite in fine powder. This will be put on the market for paint and foundry facing, and, as it has been formed at an exceedingly high temperature, it is quite pure, and possesses all of the qualities desirable for the purposes for which it is intended.

It is not the present intention of the company to enter into the manufacture of their product into finished form for the general market, but rather to encourage those who are now engaged in making up the natural graphite into articles of commerce to become buyers of their material, substituting it for that now used.

The company's plans, now being carried out, provide for the erection of a brick and iron building, 100x50 ft., on a plot of ground in Block No. 8 of the Niagara Falls Power Company's lands (adjoining the works of the Carborundum Company). Therein they will erect machinery for reducing coke to grains of the desired size, an electric furnace through which the prepared grains will pass in a continuous stream, a pulverizer for reducing the grains as received from the furnace, and a scalping sieve through which the product from the pulverizer will pass, that particles exceeding the 1/200 of an inch diameter may be removed. The final flour or powder will contain an amount of pure graphite proportionate to the percentage of impurities in the original coke. It is quite possible that, instead of using high-grade marketable coke, the fine refuse from the coke ovens, which is at present a waste material, will be utilized in the manufacture of this product.

## A NIGHT SCHOOL FOR A TELEPHONE COMPANY'S EMPLOYEES.

A recent innovation in the telephone field has been introduced by the New York and New Jersey Telephone Company to educate the employees in regard to installation and care of all sorts of telephone apparatus used by the American Bell Telephone Company. Mr. W. H. Brown, an electrical engineer, who graduated from Lehigh University in 1896, has been employed as an instructor in all branches of the telephone business.

The course of instruction, as outlined for the present, starts in with the rudiments of electrical science, and gradually leads up to the circuits involved in multiple switchboards, selective signal apparatus and power plants used in connection with telephone apparatus.

The company has divided its territory into sections, the main office of each section being the assembling point for the men to meet Mr. Brown, and to receive instructions through black-board exercises and illustrations concerning the work in all its details. So far these meeting points have been Jersey City, Newark, Paterson, Long Branch, New Brunswick, Elizabeth, Orange, West Brighton and Morristown.

The interest shown by the men has already proven that the matter of instruction in this form appeals to them in a stronger way than the correspondence system, which has been tried by the men for some time past.

The detail of a special man for this work was the outcome of classes which have been carried on in one of the districts for the last three years. The question of a form of correspondence instruction which would not be too lengthy or complicated for the men to take up at once was carefully considered by the company.

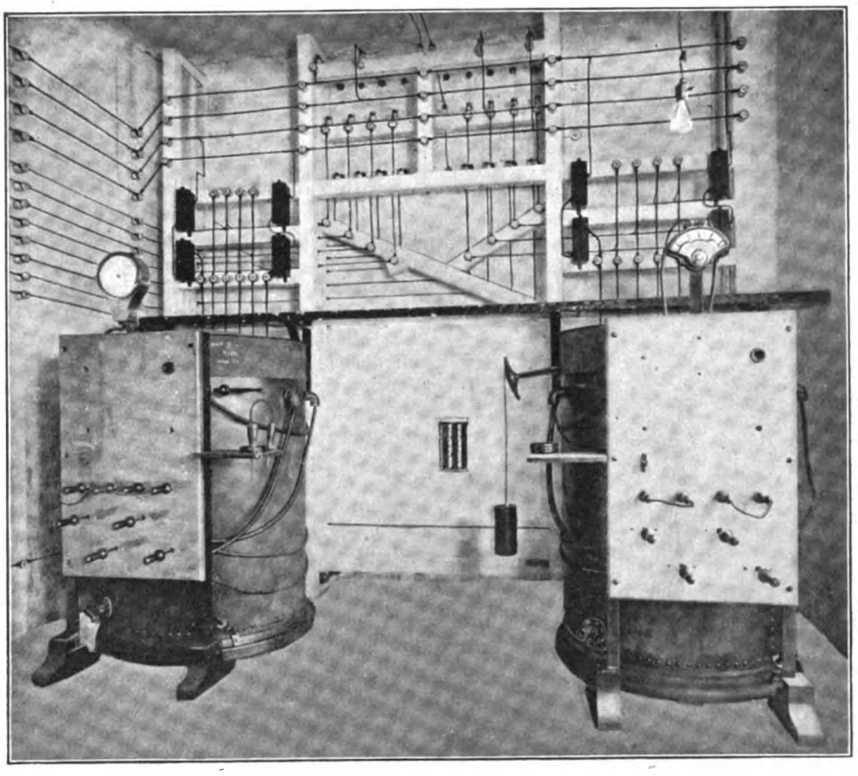
A meeting of all the employees in the New Jersey division was held in Newark to determine the value of this form of instruction for practical telephone men. This was well attended and great interest at that time was shown in the question at issue, but it was found that the men lagged in their work on account of the length of the primary work.

When it was found that correspondence instruction was out of the question a different method was eagerly looked for. The success of black-board exercises in the one district mentioned above brought the question of a special instructor to the attention of the company.

The result of the efforts of Mr. Brown

Digitized by Google

in this innovation will be watched with great interest. The classes meet in the evening at 7.30 P. M., and the lecture and explanation of diagrams and apparatus closes about 10 P. M. The time of the instructor is devoted entirely to the preparation of lectures and material for use in connection with the classes, which are held every night in the week except Sunday.



## THE SERIES ALTERNATING CURRENT ARC SYSTEM IN HARTFORD.

As has been pointed out in the convention paper by Prof. W. L. Robb, reprinted on another page, the Hartford Electric Light Company has put into extensive use the series alternating current arc lamp of the General Electric Company, supplied with current from special transformers designed to give constant current from their secondaries, their primaries being supplied with constant potential.

The Hartford Company put in one 30-light transformer of this kind in April, 1898, and followed it with the first 100-light transformer in October of the same year. The 30-lighter has now been superseded and of the larger size there are now 6 in active service, to be followed by one more which has already been ordered. The company has in service altogether some 1550 arc lamps and, as pointed out in the paper referred to above, all of these within the direct current three-wire district, whether used for commercial or street lighting purposes, are constant potential direct-current arcs run from the underground mains. Outside of and generally surrounding this district is another in which all the incandescent lamps, motors and arcs, either street or commercial, are supplied from alternating current transformers, generally on secondary three-wire networks. There remain, however, a certain number of street arc lamps which cannot be reached by either of these constant potential systems, and which were originally supplied by series arc machines. It was for these lamps that the constant current transformers have been installed in order to do away with the small series arc machines with their well known disadvantages.

The arcs are all of the enclosed type, as are all of the arcs supplied from constant potential circuits, and are given 400 actual watts each, which the company estimates gives fully as good, if not better, lighting than the old naked direct current series arcs which its contract with the city specifies should be given 7 amperes at 45 volts each. Of this 400 watts practically all is usefully absorbed in the arc itself, there being no need of a reactive coil as in constant potential work. The direct current constant potential arcs supplied by the same company are given 440 watts between terminals, of which about 140 watts is used up in the series resistance, giving only 300 watts to the arc. The constant potential alternating current arcs are given 500 real watts across the terminals, or about 400 at the arc.

The plans of the company for the future contemplate the extension of the three-wire alternating interconnected distribution network as the residence and other scattered incandescent lighting load increases, and the change of all street arcs to the constant potential type as fast as the network reaches them. The series alternating system will be retained for the outlying lights out of reach of the network only and it is estimated that the present equipment of series transformers will carry these indefinitely, all growth of business being taken up by the extension of the constant potential network, the series lines being gradually crowded out further and further as the city enlarges.

A CONSTANT CURRENT TRANSFORMER SUB-STATION.

The 6 series transformers are located in pairs at three different points, one the battery sub-station and the other two small 10x10 brick transformer stations which do not require attention. A view of the interior of one of these is shown on this page. The two transformers of each pair are connected respectively across the two phases of the two-phase 2400-volt 60-cycle network, balancing the load. The construction of the transformers is of great interest. The principle of regulation is the well known repulsion effect and its application to this purpose is broadly patented by Prof. Elihu Thomson.

Each machine is enclosed in a cylindrical tank, about which a chance remark made by one of the Hartford Electric Light Company's employees when the first one arrived upon the scene, has given the whole scheme a nickname which will probably always cling to it—the "tub" system. These tanks were originally made of boiler iron riveted up, but it has been found impossible to keep these tight against the transil oil which is used for insulation, and the new ones will be made of cast-iron.

In the interior is a transformer of the shell type, with a long, central, vertical core rising the whole length of the tank or tub, surrounded by the primary and secondary coils and with a magnetic circuit closed by return paths outside of them. The primary is made up of two independent coils, one fixed at the top and the other at the bottom of the tub. The secondary is similarly made up of two coils which are free to float up and down in the oil. These two are connected with each other by chains and levers in such a way that as one rises the other falls. They may approach into contact with each other at the middle of the tank or from this position one may rise toward the primary coil at the top while the other falls toward the primary coil at the bottom. Connected with the chains by which they are balanced is a lever which extends outwardly from the top of the oil tank and carries depending from its outer end a heavy adjustable weight. This weight tends to force the two secondary coils respectively toward the two primary coils. When the machine is in operation the currents induced in the secondary react upon those in the primary and tend to force the coils apart, which force is balanced for normal current by the adjustable weight outside

Digitized by Google

of the case. If the resistance of the secondary circuit falls due to the cutting out of lamps, the current increases slightly, increasing the repulsion effect, and the secondary is pushed further away from the primary, giving a chance for increased magnetic leakage between the primary and secondary, which reduces the e. m. f. in the secondary, bringing the current down to practically normal, even with wide changes of resistance. The regulation obtained is adjustable by means of a cam-shaped segment which can be moved on the outer end of the weighted lever and very accurate results can be obtained. Recording voltmeter charts show that the current will not vary during the night between wider limits than 6¼ and 6½ amperes, which is as good a result as can be obtained from series arc machines.

The two coils of the secondaries of these 100-light transformers are run on the multi-circuit principle, with 50 lamps in each of the two circuits, and the switching panels for controlling these are shown in the view above mentioned. As the secondary voltage is considerably higher than the primary and the machine delivers the maximum voltage on open circuit, the lines are always shut down by opening the primaries. In starting, the secondary is short-circuited, the short-circuiting plug being afterwards removed. The high voltage gives arcs of considerable length, but these are minimized by the use of a hard rubber sleeve which springs back around the plugs on pulling them out, such as is used with Brush switchboards. The primaries are protected by D. & W. enclosed fuses, two in series with each transformer. Each transformer house contains one Bristol recording ammeter, which is plugged from one circuit into the other by the inspector when he makes his rounds, thus giving a record of each visit to the house. The transformer cases are carefully grounded to prevent any risk of shock from the high voltage.

The Hartford Electric Light Company has, besides the arcs mentioned, 48,000 incandescent lights connected up and 1900 h. p. capacity in motors, a considerable load for a place the size of Hartford, which is due to the company's low rates for current and the satisfactory character of the service.

The present hydraulic equipment is therefore rapidly being outgrown and the company has commenced work on a new power station on the Farmington River, two miles above the present one. Here an additional fall of 31 ft. will be obtained, giving more power than that obtained from the present station, where the fall is only 23 ft. The equipment will differ considerably from the pioneer belted plant at the older station, and will consist of two pairs of Stillwell-Bierce horizontal turbines, direct coupled to two 750-kw. Westinghouse alternators. The current will be carried to Hartford on an aluminum line. The location of the power house is almost ideal so far as topographical conditions are concerned—the river coming through a narrow gorge with rock walls which can be dammed at very small expense. The dam and power house foundations will be of concrete, similar to those at Mechanicsville. The work is being done by the Engineering Contract Company. It is expected that the new power house will be ready for service by October 1st to help out with this year's winter load.

## A COMPARISON OF THE ECONOMY OF TWO ARC LIGHT SYSTEMS.

The earnest desire of many central station owners operating alternating current and series arc machinery to throw their whole load on to one type of generators has developed up to the present time two practical commercial methods of supplying series arc circuits with power from the alternating current machines. One of these, which has been in more or less use for two years, is the combination of an induction or synchronous motor with ordinary direct current series machines, and the other, which has only come into notice within the last few months, but has excited a remarkable amount of attention during that time, is the series alternating current enclosed arc system of the General Electric Company. Much has been written upon this subject and considerable will be found upon other pages of this paper, but little has been said in public print about that important feature, the financial outlay and income. To give an approximate idea of the dollars and cents involved, expressed as a comparison of the outlay for and economy of two systems of supplying arc lamps from a. c. mains, a representative case will be developed as follows:

Let an existing central station be assumed to have sufficient alternating current machinery to operate its arc load with either motors or series alternating system, and let it be assumed that the station has in service two old-style arc machines running 200 open arc lamps, which load it is desired to throw upon the alternators. Considering first the investment necessary for the new equipment, the following valuations may be given in round numbers:

| | |
|---|---|
| Approximate cost of a 150 h. p. motor | $2,000 |
| Inventory value of two old arc machines | 1,000 |
| Inventory value of 200 old open arc lamps | 1,000 |
| Total investment on motor dynamo plan | $4,000 |

While of course the series arc system has not settled down to standard list prices, and on the sales that have already been made allowances must be granted for the high first cost of new appartus and also for introduction rates, the approximate cost of 200 series alternating lamps with the transformers to supply them at 60 cycles can be put down in round numbers as $6,000.

Thus, if the two old arc machines and the old open lamps can be disposed of at the rates mentioned above, the laternating arcs would represent an original outlay of $2,000 more than the motor driven arrangement. Figuring interest at six per cent. and depreciation at ten per cent. in both cases, the fixed charges of the alternating arcs would be $320 per year more than those of the motor driven plant.

The comparative efficiencies of the two systems at full load, which is the normal condition of street service, may also be taken up somewhat as follows:

| | |
|---|---|
| Efficiency of a 150 h. p. alternating current motor, approximately | 92% |
| Efficiency of old arc machines, approximately | 76% |
| Total efficiency of motor driven sets, approximately | 70% |
| Efficiency of 100 light alternating series transformers | 95% |

If the open arcs are what is nominally known as 1200 candle power each, they consume about 350 watts per lamp. With an efficiency of 70 per cent. the motor would require approximiately 500 watts per lamp from the alternating current bus bars to drive the arc line.

The comparative economy of the two systems will of course depend largely upon the amount of power given to the alternating arcs, which should be such as to give the same amount of light as the 1200 c. p. open lamps. The number of watts in an alternating enclosed arc necessary to do this cannot be definitely stated, but is largely a matter of judgment. Assuming, however, that the central station manager considers it sufficient to give 400 actual watts in place of the 350 given the direct-current lamps, the series transformer with an efficiency of 95 per cent., will require from the alternating current lines 421 watts per lamp. This number of watts would probably not give as high a mean spherical candle power as the open lamps assumed, but owing to the better diffusion of the light may give just as satisfactory illumination. This figure was taken because it is the number of watts given the lamps already put in use, although it is probably hardly a fair substitute for the normal 1200-c. p. open lamp and a higher wattage might be necessary. However, the figure taken shows a saving at the alternating current mains of 80 watts per lamp in favor of the alternating arc. Figuring a daily operation of 200 lamps 11 hours for 365 days in the year, at 1c. per kilowatt-hour, the saving in power annually would be about $600.

It would be well, however, to discount this considerably owing to the small amount of energy given to the arc in the above calculation, and it probably should come down to a figure which would about balance the difference in fixed charges in favor of the direct current arcs, leaving the advisability of one system or the other to depend largely upon the relative cost of trimming, attendance, repairs and operation.

The maintenance cost of the 200 open arc lamps may be estimated at, in round numbers, about $11.50 per lamp per year for trimming and carbons, this being a fair figure with 12-in. carbons at $6 per 1000, 7-in. carbons at $3.50 per 1000, and one man trimming 100 lamps at $2 per day. The enclosed arcs with carbons at $21 per 1000 and a life of 80 hours, one carbon being used per trim, and with in-

Digitized by Google

ner globes at $.18 each and a life of 600 hours, would show a cost of:

| | |
|---|---|
| Carbons per lamp per year..... | $1.35 |
| Inner globes per lamp per year..... | 1.20 |
| Trimming per lamp per year..... | 1.65 |
| Total per lamp per year..... | $4.20 |

There is thus shown a saving of something over $7 per lamp per year in favor of the alternating enclosed arcs. This saving, of course, is not so much due to the use of alternating current at the arcs as to the use of enclosed arcs, and may be obtained just as well with enclosed arcs on the direct current series system with motor driven machines.

Another element, however, which is very hard to reduce to dollars and cents in any typical case, but which each central station manager can estimate for himself according to the local conditions, is the reduced cost of attendance and repairs, the alternating arc system requiring no motor and arc dynamos, but in their place only a transformer which may be located at the generating station or, if economy of copper so dictates, may be located in a small sub-station. The amount of floor space required is considerably less and the machine much less likely to get out of order and require repairs, rewinding, or give trouble from breakage of mechanical parts or insulation.

The general conclusion of the whole matter is that having open direct current series arc lamps and machines for supplying them—the alternating arc system will show a first cost somewhat greater than the motor driven arrangement, which amount will be repaid by its greater economy of power. The enclosed arc, as usual, shows an economy of trimming over the open and the alternating system shows a general advantage over the motor driven set in the reduced attendance and trouble.

# National Electric Light Convention.

The twenty-second annual meeting of the National Electric Light Association held in New York City, May 23d, 24th and 25th, differed very little from its immediate predecessors, the association apparently having reached years of discretion and settled down to a stable basis. This meeting, like that held three years before in the same city, was in the same building with the electrical exhibition, although the latter was unfortunately not this year as extensive, interesting or enthusiastic as the first, and up to the present the best of all New York electrical exhibitions, that was held in the Grand Central Palace three years ago.

The papers presented, most of which are reprinted in part below, illustrate the application of scientific and engineering methods to all departments of the central station business, including even the financial. It is a remarkable fact that the precise methods of thought, cultivated by the study of mathematics and the practice of engineering, have carried the business and financial departments of the central station industry to a much higher plane of perfection than the corresponding departments of any other industry.

A perusal of the following extracts from papers presented will, it is believed, illustrate this observation.

The morning session of Tuesday, May 23d, was opened as usual by the address of President Young, which reviewed the remarkable advance of electrical engineering during the last decade and particularly the development of the enormous installations now proceeding in the Greater New York. The address was followed by the following paper presented by Mr. W. S. Barstow on

### A LOCAL TRANSMISSION SYSTEM—DEVELOPMENT AND OPERATION.

The plan of the Edison Company, of Brooklyn, as originally outlined in 1896, and as finally completed in 1897, provided for the use of a three-phase, 25-cycle, 6,600-volt system, three-phase because its use was for transmission purposes only, 25-cycle because of the ease at this frequency of station operation, transmission and transformation, and a pressure of 6,600 volts because this was sufficient, with the price of copper at 18 cents, to reach economically all parts of the greater city and suburbs.

The main station, located on the water front at Bay Ridge, is called the Union Station, because it generates a current which unites all systems hitherto separately operated. From this point high-tension feeders, the majority under ground, extend to ten sub-stations, where the energy is received, transformed and distributed.

In the designing of a switchboard for high-pressure work special attention should be paid to the simplicity of arrangement and contents of such board, as the fewer the devices, the better for the reliability and success of the system. The conditions of the operation of a high-tension multiphase system, when used for distributing purposes to sub-stations, differ considerably from the requirements of a primary station with a simple distributing system. This difference lies mainly in the fact that feeder regulation in the high-tension multiphase transmission system can be almost entirely dispensed with, the sub-stations doing the necessary regulating for the energy as required by the customers. Therefore, the important requirement in the multiphase transmission station becomes simply the positive controlling of the energy generated at the machines, with possibly the operating of one or two sets of auxiliary bus bars. For the controlling of this generated energy, switches, capable of breaking a full and overload current, should be placed between the generators and the bus bars, and between each set of bus bars. This requirement will be found to be imperative. In Brooklyn these switches are operated by electrically controlled pneumatic attachment, used by the Pennsylvania Railroad system in their large switch yards. In all cases these have been positive and satisfactory in action. It is the present intention to control the interlocking circuit by a device dependent upon the synchronizing of the current, so that two machines or sets of bus bars cannot in any way be accidentally connected when out of phase. The switch itself, breaking under oil, is not in any way complicated, and has satisfactorily withstood the test of capacity and time. These main switches, placed as above stated, are the only ones in the station which will break under overload and pressure of 7000 volts, with the exception of the emergency switches. These emergency switches are plain pivoted copper

ONE OF THE ELECTRO-PNEUMATIC SWITCHES IN BROOKLYN.

blades, with a fuse in multiple, and are to be pulled only in a case of last resort in event of any accident happening to the switchboard itself.

Distribution from a high-tension multiphase plant is an important problem, particularly as regards the underground and overhead conductor systems. In Brooklyn, with a view of securing the best service on feeders, which must necessarily be overhead, heavy chestnut poles of about 45 to 50 ft. in height, and about 90 ft. apart, were used. The poles are fitted with special six-pin cross-arms. On the outside insulators of the top cross-arm are attached barbed galvanized-iron wires, which are grounded at every fourth pole. The second cross-arm carries the feeders in duplicate, three on each side of the pole. With three conductors on a hori-

Digitized by Google

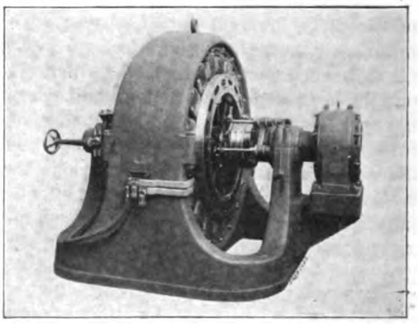
zontal cross-arm, we are able to reduce inductive effects by transpositions, which, at low frequency, are satisfactory. The insulators are of glass, of the double or triple-petticoat type, and during the two years they have been in use, no defects whatever have developed. The line is carried entirely over all obstructions, in some cases it being necessary to use 70-ft. poles. More or less trouble has been experienced with lightning, and the heaviest trunk lines have been equipped with lightning arresters.

The style of conduit used in Brooklyn may be termed a closed system, owing to the fact that it has been the endeavor to keep the entire conduit system as water-tight and dry as possible. A vitrified tile duct is used, with water-tight joints, and the brick manholes are of double construction, filled in with tar, and built on heavy concrete foundations resting upon creosoted timbers. The covers of the manholes are patterned after the Edison ten-stub junction-box top. The inside cover is provided with a rubber gasket, and held in place by bolts. The outside is simply a heavy cover, acting as a mechanical protection to the inside one. The conduit system is connected to the unused brick stacks of the stations in which steam has been removed and transforming apparatus substituted. In addition, a blower is operated at the Bay Ridge station. The movement of air through such a large system, composed of some 100 miles of duct, is very slow, and yet it is sufficient to keep the system in good condition.

The reason for the adoption of a tile conduit as moisture-proof as possible was in the main on account of electrolysis. In making preliminary tests along the proposed line of conduit it was found that the pressure from metallic substances to ground varied from 10 volts negative to 26 volts positive. Thus it would only be a question of time before the heaviest lead cover would be totally destroyed. It was also found that the only solution was to make the lead cover of the cable negative to ground throughout the entire system. This demanded that all stray currents should always flow to the lead cover and should never leave it. Such a condition required that the lead covering of all the cables should be connected to the negative bus bars of the railroad power houses by insulated conductors of low resistance.

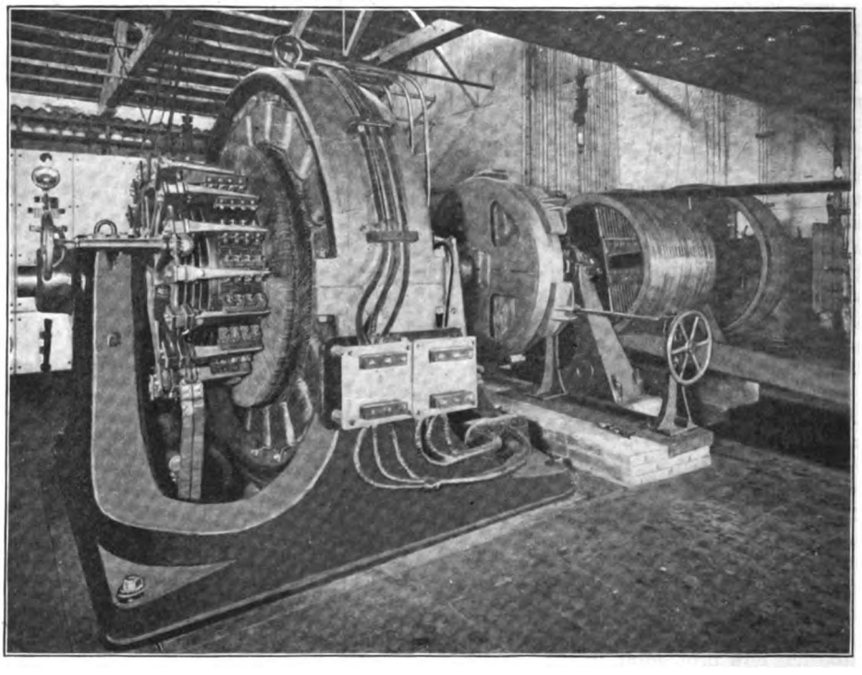
The question of mechanical covering for the cable itself depends upon the nature of insulation, the liability to electrolytic action or the effect of gases. Paper cables must necessarily be covered by lead or other moisture-proof material, the life of the cable depending upon such moisture-proof covering. Rubber cables, when subject to electrolysis, can be protected by a covering of water-proof asbestos surrounded by a very heavy braided covering, put tight and thoroughly saturated with compound. In Brooklyn all cables, whether rubber or paper insulation, are covered, wherever they pass through manholes, with heavy asbestos tape. In case a burn-out occurs on a cable with 1000 or 2000 kw. behind it, such an arc and heat is developed that injury is apt to result to adjacent cables, and it was found that by protecting each cable in this way further damage has been prevented.

---



During the afternoon session the only paper presented was that of Prof. W. L. Robb on

ROTARY TRANSFORMERS AND STORAGE BATTERIES AS RELATED TO LONG-DISTANCE TRANSMISSION.



The main source of power is water power on the Farmington River, approximately eleven miles from Hartford. The water power at present developed is capable, under the most favorable conditions, of delivering at the switchboard in Hartford about 1200 electrical horse-power. The power is generated by two 600-kw. 60-cycle alternators and transmitted to Hartford on the three-phase system under 10,000 volts pressure.

The water power is supplemented by an auxiliary steam plant in Hartford, consisting of two compound-condensing Cooper-Corliss engines, having a combined capacity of 1600 horse-power. These engines supply the power to operate one 600-kw. alternator and one 400-kw. rotary transformer, so arranged that it can be connected with engines and operated as a direct or alternating-current generator. This rotary is so operated whenever, owing to low water or repairs on the transmission line, the supply of alternating current is insufficient for the alternating-current load and all the rotary transformers.

Two systems of distribution are used. In the central portion of the city the distribution is on the three-wire, 220-volt, direct-current system. This part of the service is practically all underground. The feeders are lead-covered cables drawn in cement-lined ducts. The distribution is in part by Edison tubes and in part by lead-covered cables drawn in ducts. Outside the central portion of the city the feeders are supplied with two-phase alternating current under 2400 volts pressure, and the distribution is, in general, on three-wire, 220-volt systems, supplied from ten or twenty kw. transformers, although a few smaller transformers are still in service. This service is in part under ground, but, in general, overhead. Constant-potential, inclosed-arc lamps, incandescent lamps and motors, in the case of both alternating and direct currents, are operated on the same three-wire system. All the commercial arc lamps, whether on the direct or alternating system, are of the constant-potential, inclosed type, as are also the street lamps in streets in which there is a three-wire system. In other streets the street lamps are of the series alternating-current, in-

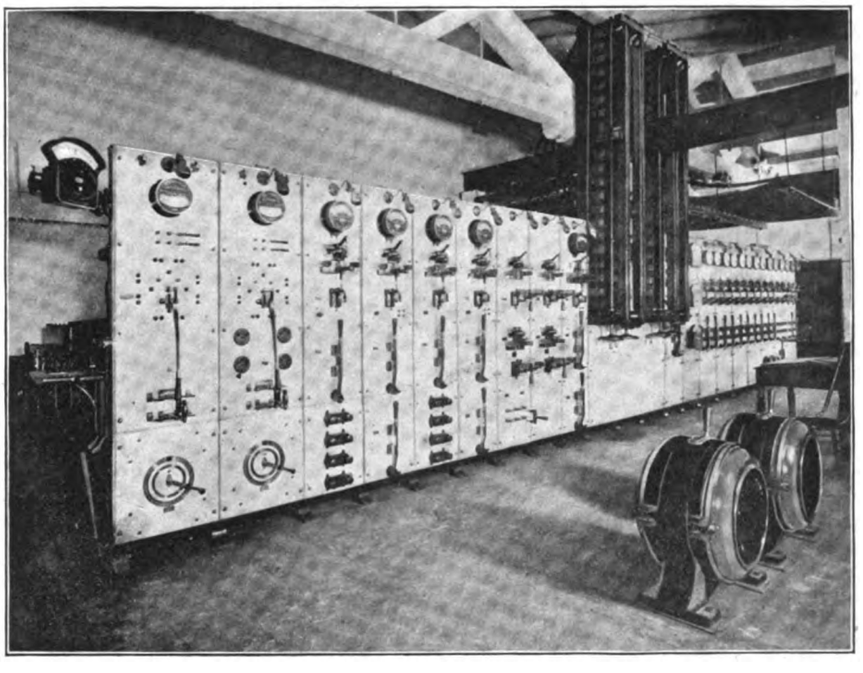
THE 400 KW. CONVERTER, SHOWING CLUTCH AND BELT BY WHICH THE MACHINE IS USED AS A GENERATOR OR MOTOR.

Digitized by Google

closed-arc type, and are operated from constant-current transformers.

Three rotary transformers supply direct current to the three-wire, direct-current system. One, mentioned above, has a capacity of 400 kw., and is located at the steam plant. Two have a capacity of 250 kw. each, and are located in a battery sub-station which is situated in the very heart of the business section of the city, and about three-quarters of a mile from the steam plant. The storage battery has a capacity of 2500 horse-power hours at a five hour rate of discharge. All three rotaries and the battery supply currents to the same three-wire system.

The three alternators are always operated in parallel. At least one rotary transformer and storage battery are always connected to the three-wire, direct-current system. The direct and alternating-current systems are consequently interlocked, and the whole plant, including alternators, rotary transformers and battery, is practically operated in parallel.



The rotary transformers are of two-phase type, and are so designed that by cutting in or out turns of the primary of the transformers the voltage of the rotaries may be varied betwen 230 and 360 volts. This wide range of voltage is necessitated by the fact that the rotaries are at times run directly on the line, and at other times used in charging the battery, frequently at high charging rates. This wide range of voltage that can be obtained from the rotary does away with the boosters, otherwise necessary in charging.

The rotary transformers are two-wire, and simply supply the current to the outside wires of the three-wire system. The neutral wire is connected with the middle point of the secondaries of the two transformers. This point is always midway, as regards electric pressure, between the two terminals of the rotary transformer.

The three alternators, one operated by steam and the other two operated by water power at a distance of 11 miles from the first, have been continuously run parallel during the past thee years. No difficulty whatever has been found in this method of operation.

The operation of the rotary converters has not been so simple a matter. At the outset there was excessive sparking at the commutator. This sparking was soon found to depend very largely on the variety of brushes used. It was found that a very soft carbon brush gave the best results, but without special treatment of the brushes, sparking, although diminished, is still excessive. The method of treating the brushes suggested by our superintendent, Mr. Rollins, was tried and found effective. The carbon brushes are first raised to a red heat, and then plunged in ordinary lubricating oil and allowed to cool. When brushes treated in this manner were used all vicious sparking was stopped, and in this particular the converters ran as smoothly as direct-current generators of the best type. At the outset, in operating the rotaries, considerable difficulty was met with in preventing pumping when the engines were supplying power to the system. This pumping could be traced to the variation in the angular speed of the engines, and when the water power alone was supplying the power there was little, if any, pumping. It was found that this tendency to pumping could be checked by varying the field excitation of the rotary transformers or by temporarily throwing a portion of the load on the storage battery. Only once in the past three years has the pumping been such as to cause any serious interruption. The switchboard at the sub-station was originally arranged to give the greatest possible flexibility in operation. Both rotaries could be run in multiple, feeding into the line, and the excess of current used to charge the battery; or one rotary could be run on the line and the second rotary used to charge the battery independently. This last method of operation was found impracticable. Under this condition the pumping would immediately begin, and it necessitated giving up this method of operation. Notwithstanding the above-mentioned difficulties, when a year ago it was decided to increase the direct-current machinery, we had gained sufficient confidence in the rotary system to purchase a 400 kw. rotary rather than a direct-current generator.

The third rotary, when tested, proved to be free from any tendency toward pumping, either when operated from the steam plant or from the water power, and was in every way as nearly perfect as a machine could be. However, when thrown on the line with the two older rotaries, they immediately began pumping, and it was found impossible to run the three rotaries together. The pumping in a rotary system seems to be cumulative; it is very easy to stop it if the proper remedy is applied as soon as the first tendency to pump is noticed. If allowed to go on it quickly gets beyond control. The impossibility of running the three rotaries together necessitated some change. The Westinghouse Company's engineers maintained that the corrective device could be applied with equal effect to any one of the three rotaries. Copper strips were attached to the pole-pieces of the 400 kw. rotary. This rotary, of itself, was all right, but the developing of any tendency of the system towards pumping was entirely overcome by means of these copper strips. The system now works perfectly, whether operated by steam or water power. Even under the trying conditions of running the rotaries under different voltages, two feeding directly into the line and the third independently charging the battery, no trouble with pumping is experienced. In all other respects the rotary transformers have been all that could be asked for; they have run practically continuously night and day for nearly three years and have had practically no repairs, the commutators simply being turned down once or twice a year.

THE SWITCHBOARD OF THE HARTFORD ROTARY AND BATTERY STATION.

The transformer and battery station is operated by three men; the superintendent, an expert in the care of batteries, and two switchboard attendants. The labor in caring for a station of this output is a minimum.

To sum the matter up, my Hartford experience has convinced me that the most satisfactory method of supplying electric energy over a considerable area is from a central power station generating alternating current; the current being distributed to rotary and battery sub-station of high voltage, and the energy locally distributed on the three-wire, direct-current system, except in outlying districts where it will prove most advantageous to distribute on the alternating current system.

The first paper presented at the session held on Wednesday morning was by Herbert A. Wagner on the following subject:

SINGLE-PHASE DISTRIBUTION.

Probably the best example of pure single phase distribution on a large scale is furnished by the Missouri-Edison Electric Company, of St. Louis, and I can best show its possibilities by describing the results obtained by this company.

In a large portion of the city the usual system of individual transformers for every customer or adjacent customers is used. The current for these transformers is supplied by overhead feeders and distributed over high-tension overhead mains. In some districts one transformer is used to supply current for an entire block by means of three-wire low tension secondary mains.

The principal business portion of the city is now supplied by underground conductors, covering a district of forty miles of streets. A low tension Edison three-wire network of mains is used throughout this district, and these mains are supplied by high tension feeders, each of which terminates in a transformer of the same capacity as the feeder. Pressure wires run from the mains near the terminal of each transformer back to the station. Each feeder has a regulator or booster at the station.

ONE OF THE LARGE GENERATORS OF THE MISSOURI-EDISON COMPANY IN ST. LOUIS.

From this network of three-wire single phase alternating current mains current is furnished for incandescent lamps, arc lamps and motors. There are at present about 1,000 h.p. of single phase motors in operation, varying in size from ½ h.p. to 25 h.p. Many of these have replaced direct current 500-volt motors, and there is not one that is not giving perfect satisfaction. Current is charged for entirely by meter.

The most novel feature of this system is the transformer and the method of making it practically a part of the feeder to which its drop is added and is cared for by the feeder regulator at the station. The pressure wires indicate the pressure on the secondary mains which can be kept constant, however much the drop in feeder and transformer may vary.

The transformers were designed for remarkably high average efficiency, and actually show the highest efficiency at about one-quarter load. The specifications for these transformers limited the iron loss to 250 watts, the copper loss at full load to 3200 watts, and the regulation to 4 per cent. Thirty of these, of 110 kw. capacity each, are in service on as many feeders. They all run slightly under the specified losses.

The feeder regulators at the station make it possible not only to regulate the pressure with the greatest precision, but to divide the load between the feeders and their transformers in any way desired. By slightly lowering the pressure on one feeder, and slightly raising it on an adjacent one, a large proportion or all of the load of the first can be transferred to the second without sensibly altering the pressure on the mains. This operation is almost identical to that of dividing the load between two direct current generators running in parallel. All feeders can be kept almost equally loaded in this way if desired.

It is our custom to plot quite frequently curves, showing loads on all feeders in a district, for the purpose, among others, of establishing the best pressure wire to adopt for a period as standard for general regulation. The bus bar pressure is always regulated by the indications of this standard pressure wire, and the individual feeders whose pressure departs from the standard, up or down, are regulated independently, from time to time, by their own regulators.

All feeders are provided with fuses at the station end, and the secondary terminals of each transformer are led into junction boxes provided with copper fuses. These fuses are intended to protect the rest of the system in case of any defect development in a feeder or its transformer.

The method of eliminating the effect of transformer drop by making it a part of the feeder renders it possible to regulate, with a system of interconnected mains and the use of pressure wires, as closely as in a direct current system; and the use of individual feeder regulators enables the pressure to be adjusted with the greatest precision.

The ratio of current delivered to customers as shown by customers' meters to the actual station output as shown by the station wattmeters, while not an exact measure of the distribution efficiency, owing to the losses in the customers' meters and their failure to record properly at small loads, is nevertheless a good indication for relative comparison. On the single-phase underground distribution system described, this ratio of customers' meter readings to station output reaches 86 2-10 per cent. The meters used on customers' premises are the most recent type of induction wattmeters. The station meters are of the Thomson recording type, and these are carefully checked by the half-hourly records of station indicating wattmeters, both being frequently calibrated. While this figure may be the highest on record it has been obtained with such great care month after month that I feel great confidence in its accuracy. The greater portion of the overhead distribution of this same company is of the usual form with individual transformers to each customer as already stated. A large portion of the current supplied in this way is used in residences, and consequently the load factor is very low. The meters used in this work are recording ampere meters which let a considerable amount of current slip by unrecorded with light loads. The transformers are all of modern design and of high efficiency for their size. It may surprise you, however, when I state that the ratio of customers' meter readings to station output in this overhead distribution is only 48 3-10 per cent. I am also as positive of the accuracy of this low figure as of that of the remarkably high one for the underground system.

---

In the afternoon session of Wednesday the first paper presented was that of Mr. E. A. Leslie on

NOTES ON UNDERGROUND DISTRIBUTION OF TWO-PHASE CURRENT IN NEW YORK CITY.

The company with which I have the honor to be connected decided about two years ago to substitute two-phase for single-phase distribution, but one of the very first difficulties encountered was the subway situation. The trouble is that with so many occupants of the conduits it is not practicable to provide room under ground for junction boxes, large transformers and other apparatus necessary for a reliable system of meshed conductors, without which no company can, in my opinion, hope to compete to advantage with direct-current distribution.

Without junction boxes we were afraid to mesh our conductors, and for this reason and the possibility of patent complications we adopted the four-wire method.

Digitized by Google

consisting of two circuits, the currents thereon differing ninety degrees in phase. These circuits are operated practically the same as single-phase circuits, except that their distributing mains necessarily parallel each other, and, therefore, while with single-phase distribution we formerly employed but one distributing main in any given section, we now employ two. This is, of course, necessary to enable us to supply current for power purposes in units of 5 h.p. or over; but it also has this decided advantage, that it enables us to provide, at slight expense, a second source of supply for lighting and single-phase motors, in large and important installations, where an interruption of considerable duration might result in serious consequences. For this purpose a special non-arcing switch (Fig. 2) is provided, making it perfectly safe for any one to throw over from one circuit to the other the heaviest loads our largest customers are ever likely to use. These loads sometimes reach as much as 100 kw., but as our generators, ranging in capacity from 300 to 450 kw. each, all run in parallel, and the circuits consequently are all fed from common bus bars, the unbalancing effect of such switching over is rarely felt to an annoying degree. Of course, it is always desirable to preserve a fairly good balance, and these switches are frequently employed for this very purpose.

The most serious difficulty encountered was the switchboard and regulating apparatus. Formerly our generators were small, not exceeding 60 kw. each, and as they were run independently, the number of lamps connected on each circuit was necessarily governed by the capacity of the machine, and the regulation of the pressure was usually effected on the machine itself. The loads rarely exceeded 25 primary amperes, and could be switched from one generator to another without serious danger of arcing or practical interruption to the circuit. With

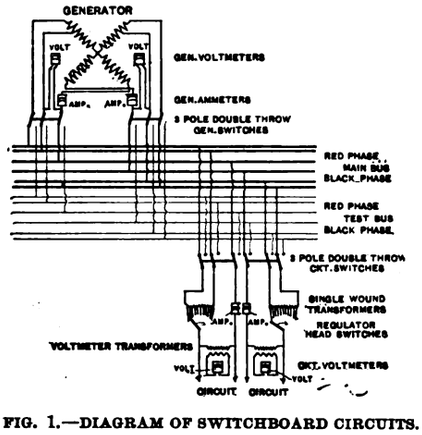

FIG. 1.—DIAGRAM OF SWITCHBOARD CIRCUITS.

the adoption of the two-phase system, however, generators of from 300 to 450 kw. were substituted and run in parallel; the number of circuits was largely reduced, and the loads on those remaining were increased to 100 amperes. We quickly found that we could not throw loads of 100 amperes at a pressure of 2,500 volts on the ordinary switchboard without dangerous arcing and annoying interruptions to lights and motors. Neither could we satisfactorily regulate our pressure. In order, therefore, to secure safety and convenience, and at the same time control the pressure of each circuit independently of the others, it became necessary to adopt a special form of switchboard and regulating apparatus, as shown in Fig. 1, which was devised by Mr. W. F. Wells, the assistant general manager of the Manhattan Electric Light Company, of this city, and a brief description of which may be of interest.

We brought out a third lead from the stator armatures of our generators, as shown in sketch, so as to give us 10 per cent. of the total voltage; that is, with the machine generating 2,500 volts on each phase, we should have between leads Nos. 1 and 2, 250 volts; between Nos. 2 and 3, 2,250 volts, and between Nos. 1 and 3, 2,500 volts. The six leads from each machine (three on each phase) are carried through a three-pole, double-throw switch in the switchboard to the 'bus-bars, of which there are two sets of six each, as shown. Ordinarily, but one set

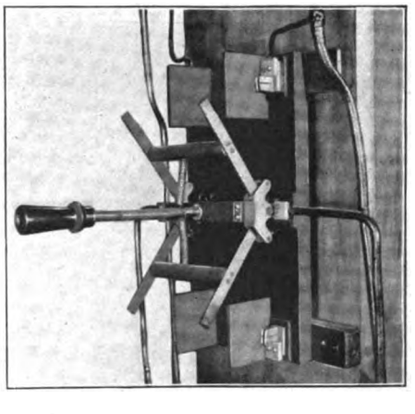

FIG. 2.—NON-ARCING THROW-OVER SWITCH.

of bus bars is used, as the generators are run in parallel, the other set being held for testing or the operation of a circuit singly if desired. The circuits are connected to these bus bars by similar switches. Lead No. 3 from the switch, after passing through an ammeter, goes direct to the circuit. Leads Nos. 1 and 2 are connected to the terminals of a single-wound transformer, sometimes called an "auto-transformer" or "economy coil." This coil has eleven leads brought out, dividing the coil into ten equal parts, each part representing 1 per cent. of the total primary voltage. These eleven leads are carried to an eleven-point switch of the regulator-head type, so that any potential between 90 per cent. and full voltage of the machine (in 1-per-cent steps) may be run on the circuit. We are, therefore, able to keep the station end of the circuit within one-half of 1 per cent.

Plug and cable connections were also added to the board in case greater subdivisions of circuits were needed than could be obtained on the two sets of 'bus-bars. The synchronizing devices and pilot lamps of the machines are connected across the 10-per-cent. coils, and, therefore, switchboard transformers are not required for these purposes. A view of this switchboard is shown in Fig. 4.

TESTING FOR FAULTS.

Notwithstanding the greatest care in the selection of insulation and the most rigid specifications for the guidance of manufacturers, faults will occasionally

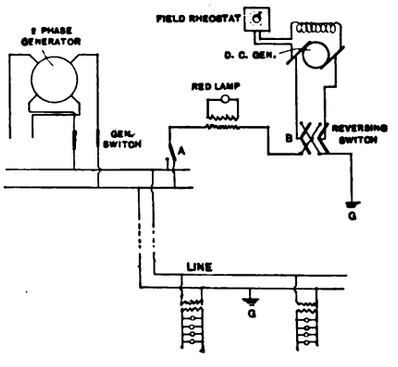

FIG. 3.—METHOD OF LOCATING GROUNDS.

develop in our cables, which are due either to inherent defects or lack of proper mechanical protection. In such cases the necessary interruption to the circuit for purposes of repair is an exceedingly important matter, and, if frequent or long drawn out, will invariably result in loss of prestige and business. Therefore, to facilitate the removal of the fault as much as possible, it was formerly our practice, whenever one of our alternating circuits became earthed, to isolate it from the other circuits by throwing it on the "test" bus in connection with a spare generator and use a device for locating the trouble, which was designed by Superintendent Sparrow, of the Manhattan Company. It includes the apparatus shown in Fig. 3, herewith :

A single-pole, double-throw switch A is attached to the test bus and from the center of this switch a lead is carried through the primary of a transformer which has a red lamp connected across its secondary; then through the ammeter to the diagonally opposite outside poles of a double-throw, double-pole switch B; from the other outside poles a wire is carried to ground. Current is supplied to the center connections of this switch by a small direct-current, shunt-wound generator having a capacity of about 10 amperes at 250 volts, and by means of this reversing switch the current can be sent through the circuit in either direction. In locating trouble the direct-current generator, which is belted to a 5 h.p. motor, is started and the single-throw switch A thrown on either side of the bus. If the red lamp lights up, it indicates that the ground is on the other leg, and the switch is thrown over. The direct current is then brought up to about 7 amperes, and the reversing switch B is thrown about every 15 seconds, which reverses the direction of the direct current flowing through the cable to the ground. The subway workmen then start out with a

Digitized by Google

compass and go to a manhole through which the circuit in question passes. If, on laying the compass on the cable, the needle reverses every 15 seconds, they know the ground is farther from the station; if, however, the needle is not affected every 15 seconds, it indicates that the trouble is between the manhole opened and the station, and they then open another manhole nearer the station. In this way they are able, without cutting the cables, to locate the trouble in a section between two manholes or handholes, or possibly in a manhole; whereas prior to the use of this device we were frequently obliged to cut in fifteen or twenty places before locating the fault. In some cases, if the trouble is slight, we are able to repair it without shutting down the circuit, as the men are provided with rubber boots and rubber gloves drawn on over buckskin gloves, and an insulated box to stand upon, and can safely and quickly make a temporary joint that will answer every purpose until such time, say early the next morning, as the circuit can be shut down without detriment to the customers. If, however, the trouble is extensive, the circuit is shut down

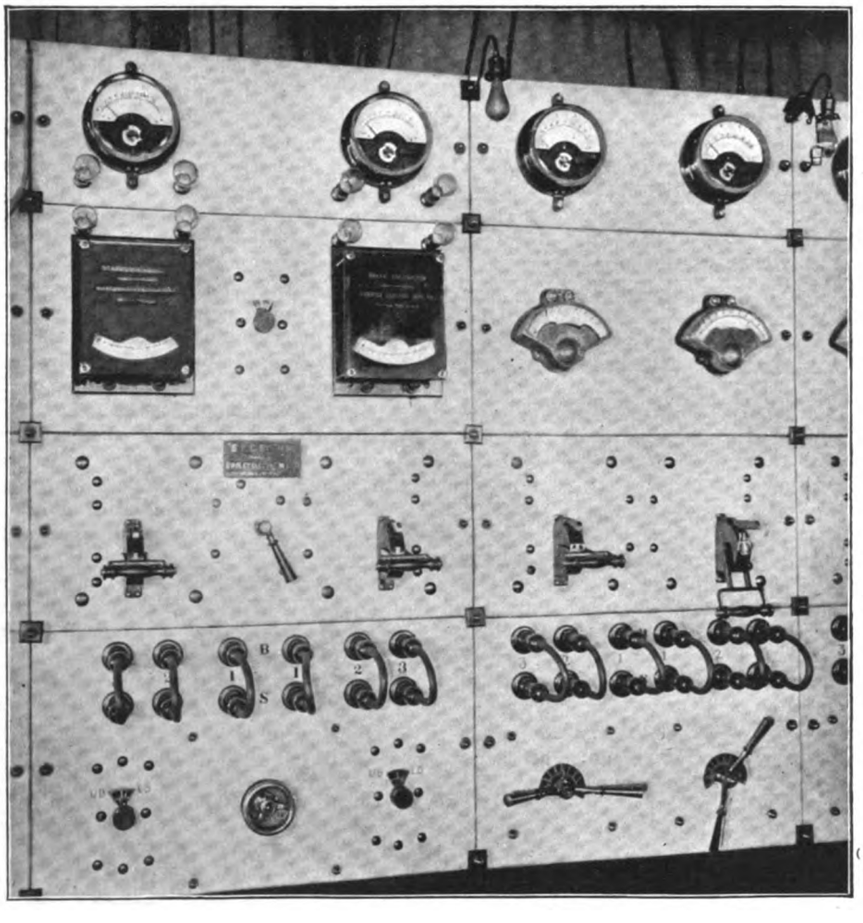

FIG. 4.—ONE MACHINE AND ONE LINE PANEL OF SWITCHBOARD.

at once and the repair made as promptly as circumstances permit.

Unfortunately, however, the subway company objects to the circuit being run, even on an independent generator, while we are locating the trouble, and therefore we now pull the circuit at once and make the test in the same way, except that we use two compasses, as the direct current flows through the primaries of the transformers and tends to mislead the men if they use but one. A compass is placed on each cable, and as long as both needles are similarly affected they know that the trouble is beyond them; when, however, the needles tend to point in opposite directions, they know that they have passed the trouble, and its location is then easily determined.

It is, perhaps, curious to note that when the alternating current is on the circuit the direct current apparently does not flow through the primaries of the transformers. Trouble on series arc circuits is also located in this way, except that not more than about four amperes of current is used, because otherwise the cut-out magnets tend to act and throw the regular lamp magnets in circuit, the resistance of which practically stops the flow of the current.

### TESTING FOR INSULATION RESISTANCE ON LIVE CIRCUITS.

It often happens in running a large number of circuits from a common bus, that phenomena will arise that have a suspicious look and make it desirable to find out which particular circuit or circuits has caused the disturbance. It would have been disastrous to the money-making end of the business if every time something unusual manifested itself we had made a practice of pulling circuit after circuit until the delinquent had been detected, and it therefore became desirable to be able to make reliable insulation tests while the circuits were in actual

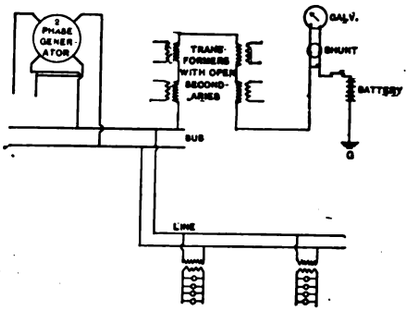

FIG. 5.—METHOD OF MEASURING INSULATION RESISTANCE.

operation. In order to accomplish this, an arrangement of apparatus was devised, such as is shown in Fig. 5, and which is described as follows:

A spare generator is started and connected through its switches to the test bus. From this bus a line is carried through a high-tension switch and then through the primary coils of four transformers in series, the secondaries being left open, as shown in the diagram. This line is then carried through the galvanometer, which is provided with the usual short-circuiting key and shunt; thence it goes to a battery of 100 chloride cells equipped with reversing key, and thence to earth. The transformers used are of the ordinary 2,000-volt type (which is the pressure used on the system), and are of about 2 kw. capacity each, which we have found by experience to be about the right size. The coils being in series, they offer very high inductive resistance to the passage of alternating current, but their resistance is practically nothing when measuring megohms with direct current.

In making the test we first ascertain the insulation resistance of the generator, test bus, leads, etc. The circuit is then thrown on the test bus and tested in the same manner as if it were not connected to a high-tension generator, with the exception that it is not necessary to allow any time for charging or discharging the cable. This is called a "hot" test. The results are the same on testing either leg of the circuit, and the insulation resistance is generally found to be anywhere from 15 per cent. to 75 per cent. lower when tested "hot" than when the circuit is disconnected from the generator and tested in the ordinary way; that is, "cold," although the lower the insulation of the circuit, the closer the two tests appear to agree

When this device was first put into service, and we had convinced ourselves that the readings obtained were really useful, we became impressed with the idea that perhaps we might be able to note the actual effect of the strain of the pressure upon the insulating material surround-

Digitized by Google

ing the conductors, and to this end a special set of tests was made.

While the results were too indefinite to be regarded as at all conclusive, they nevertheless point to the fact that the insulation of circuit does depreciate, for the time being, while under the influence of high potentials.

THE USE OF THE TELEPHONE IN UNDERGROUND TESTING.

It has been found by experience that underground circuits, particularly those employed for series arc lighting, need periodical overhauling, otherwise weak spots will accumulate to such an extent as to bring down the total insulation resistance below the standard requirements. At such times a great many galvanometer tests are necessary, and it was found that the work could be done much more quickly if the galvanometer were set up in the station instead of being moved from place to place along the street. The great objection to this, however, was the necessity for frequent communication between the foreman of the subway gang and the tester in charge of the galvanometer, obliging the former to use the public telephones a great many times during the day, which was decidedly inconvenient and involved much loss of valuable time. To overcome this serious objection, Mr. Sparrow and his assistant, Mr. L. A. Jenkins, caused to be constructed a special telephone set for use on underground cables, which works very satisfactorily.

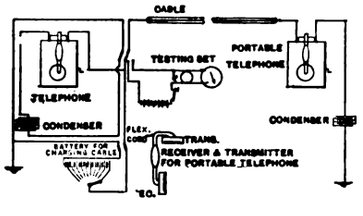

FIG. 6.—TELEPHONE CIRCUIT.

The magnetos, instead of being wound, as ordinarily, for 10,000 ohms, are wound to ring through 50,000 ohms, and a battery is placed inside of the magneto box, the transformer and receiver being mounted on a separate L-shaped piece connected by a flexible cord to the magneto box. The impedance of the series arc circuits, when used for telephoning, is very great, owing to the capacity of the rubber-covered, lead-sheathed cable, and, in order to talk successfully, it was found necessary to use condensers in connection with both telephones. With their use we are able to hold conversation over our longest series arc circuit, which is twelve miles under ground and three miles overhead, and contains 65 lamps. The method is very simple, as may be seen from the accompanying diagram, Fig. 6. The telephone at the station end, except at time of test, is left constantly in circuit. When the subway foreman has completed his arrangements for a test he connects his telephone, one wire to the copper of the cable and the other to the lead sheath; calls up the tester and so advises him. The foreman then disconnects his 'phone, and the tester does likewise, at the same time switching in his galvanometer. The latter then makes his test and throws his telephone back into circuit. After the lapse of three minutes the foreman also reconnects his telephone and calls up to know the result of the test and get further instructions. In this way the work of overhauling and renovating is very much facilitated, and the cost of maintenance and repair sensibly reduced.

This paper was followed by one presented by Mr. W. L. R. Emmet on

MEANS OF ATTAINING SAFETY IN ELECTRICAL DISTRIBUTION.

With the simplest arrangement of a primary and secondary circuit as they are now generally installed in this country, there is great liability of the existence of dangerous conditions. There are two connections that may be accidentally made; one giving a cross between primary and secondary, either in the transformer or out of it, and the other, a connection of one of the primary leads to ground. The primary voltage being 1,000 and the secondary 100, the making of these connections immediately establishes a potential difference of 1,100 volts between part of the secondary circuit and the ground. This pressure will, as a rule, be too much for the insulation of combination fixtures, and the first indication of trouble is likely to be a fire, if it be not a shock received by someone who happens to establish a circuit through his body between the ground and some lamp socket or other part that is not sufficiently insulated from the secondary circuit. The method of installation described is almost universally adopted wherever alternating currents are being used in this country. It is, in fact, virtually compulsory upon the average station manager, since no established method of overcoming the difficulty is available that does not violate the fire underwriters' rule that all house wiring shall be free from any connection to ground. If this rule is disregarded, we may ground one side of the secondary, which entirely overcomes the difficulty, and which is open to no objection except that the insulation between one side of the secondary and ground is subjected to the voltage of the secondary circuit.

So long as the secondary circuit remains insulated from ground, these dangers will exist. The remedy for the trouble must be either in the permanent connection to ground, which is now prohibited by one of the underwriters' rules, or in the installation of some device by which the secondary is grounded automatically when the emergency arises.

As I have said, the permanent grounding of transformer secondaries is prohibited by the fire underwriters' rules, which prohibition is generally respected throughout the country, so that most secondary circuits are entirely unprotected from the trouble above described. There are, however, some very important exceptions that afford useful examples of the safety of operating secondary circuits with permanent ground connections. I allude to some of the large Edison companies which have recently installed high-tension alternating apparatus to supply power to existing three-wire systems through rotary converters. In a rotary converter the collector rings and commutator connect to the same winding, so that the direct-current leads are as much a part of the transformer secondary system as if they were connected directly to it. Most of these large Edison companies have for years been operating with neutral conductor grounded. This grounding has in most cases first occurred through chance or accident, and the practice has been persevered in, partly because it would be a difficult matter to avoid neutral grounds, and partly because the grounded neutral is, for several reasons, very desirable.

In these cases two rules of the National Board of Fire Underwriters are violated: First, the secondary system to which all house wiring is connected is permanently grounded; and, second, a primary voltage of 6,000 is used, while the underwriters' rules state that house wiring must not be connected to the secondaries of transformers whose primaries receive current at voltages above 3,000. In spite of these violations, the circuits are just as safe as they were before the high-tension power was used, and safer than they were before their neutrals were grounded, although at that time no high-tension apparatus had been installed. Both of these rules should, and in time will, be abandoned; the first, because it leads to danger rather than safety; and the second, because it endeavors to fix an unnecessary barrier to progress. The interests of insurance companies, as well as of users and manufacturers of electrical apparatus, are best served by the introduction of methods which conduce to economy in the broadest sense.

A forcible illustration of the danger of ungrounded secondaries is afforded by a recent occurrence in New Orleans. In a certain residence district, where houses were connected to a system of three-wire alternating mains, a cross caused by wind occurred between one of the main wires and a 2,000-volt primary wire in the same street. The result was that the insulation between wiring and ground was broken down in a large number of houses, the trouble being principally in combination fixtures where conductors were near gas pipes. Fires occurred in twenty houses and several were totally destroyed, among which were some fine residences. The loss was over $200,000. If the neutral of this system of mains had been grounded, this trouble could not have occurred.

The third cause of danger in electrical distribution is arcing through accidental opening of circuits or through failure of circuit-opening devices. Fuses, switches and circuit-breakers are subjects upon

Digitized by Google

which a great deal could be said in discussing means of attaining safety. Many of the circuit-opening devices that have been introduced in the past have been capable only of breaking certain definite currents, and incapable of coping with the conditions existing when a very large system is short-circuited. Most of the switchboard devices that are now in use for alternating work are strictly limited in the range of their safe action, and would be valueless on a circuit capable of delivering a large amount of power.

In the past, alternators have been generally used singly and in comparatively small units; the total power that could be delivered to one point being limited to the maximum output of one machine. In many of the installations now being made, numbers of large machines are being run in parallel, and the power that can be delivered at any point is consequently large, and the difficulty of breaking the current that flows in case of short-circuit is correspondingly great.

In the new station of the Metropolitan Railway Company, about 50,000 kw. will be delivered to a single set of bus bars, and from there distributed all over the city. Wherever a sub-station or other installation is connected to these lines, means must be provided by which the circuit can be broken instantly in case a short-circuit occurs. The power of this station is generated and distributed at 6,000 volts, and the loss in lines will be small, so that the violence of a short-circuit in a sub-station will be almost as great as if it were on the main bus bars.

We have recently done a good deal of work on circuit-opening devices for such heavy duty. One of the principal troubles in such work is the difficulty of making experiments. We have a testing outfit at Mechanicville with which we can get from 300 to 400 amperes at 15,000 volts with an inductive load, and at Niagara Falls I have tested some devices with 700 amperes and 13,000 volts and a highly inductive load, the voltage rising to 18,000 when the circuit was opened. In comparison with past experiences these conditions seem heavy, but they are light when compared to those which must be met in some plants that are now being installed.

There is, of course, a limit to the capacity of every circuit-opening device, and as power units become enlarged it will be necessary to provide means for limiting the total amount of power that can be delivered to individual branches. This object can be accomplished by inserting reactances in these branches; such reactances can be so proportioned that they do not materially interfere with the normal operating conditions, and, at the same time, they can so limit the total power delivered that it is kept within the safe range of the circuit-opening devices. Up to the present time, such reactances have not been much used.

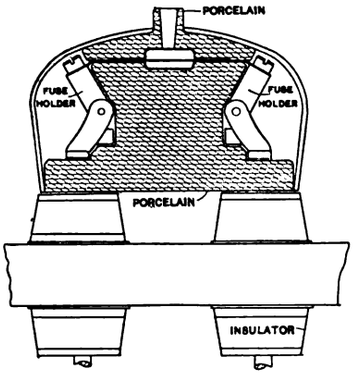

FIG. 1.—AN EXPULSION TYPE FUSE.

I have prepared sketches of a few circuit-opening devices that have resulted from recent investigations and experiments, and will briefly describe their design.

Fig. 1 shows a fuse block in which the fuse is in a state of tension between two hinged terminals; these terminals are pulled apart by springs and receive current through flexible connections. The fuse is punched out of sheet metal, the narrowest portion being at the middle. It is placed between two blocks of porcelain, a small amount of clearance being provided where the fuse passes through, so that its ends can be freely withdrawn by the movable terminals after the narrow part of the fuse has become ruptured. Around the narrow part of the fuse the porcelain blocks are recessed so as to provide an air chamber; this chamber is vented by a hole in the upper block. The whole device is firmly clamped together, so that the only opening to the outer air is through this one vent-hole. The fuse, being under tension, does not quite reach the melting point before the break occurs. It loses its tensile strength at a low red heat and pulls apart. It is quickly withdrawn by the springs from the air chamber in which it has been broken. A very small amount of the metal is volatilized and its gas is blown out of the vent-hole. For the purpose of preventing any deposit of metal fumes on the porcelain surfaces, these surfaces are lined with muslin that has been treated with shellac or varnish and pressed into the desired shape. This lining covers the interior of the chamber in which the fuse is broken and the porcelain surfaces between which the fuse is drawn. These linings are supplied with the new fuses and are renewed if any appreciable amount of burning has occurred.

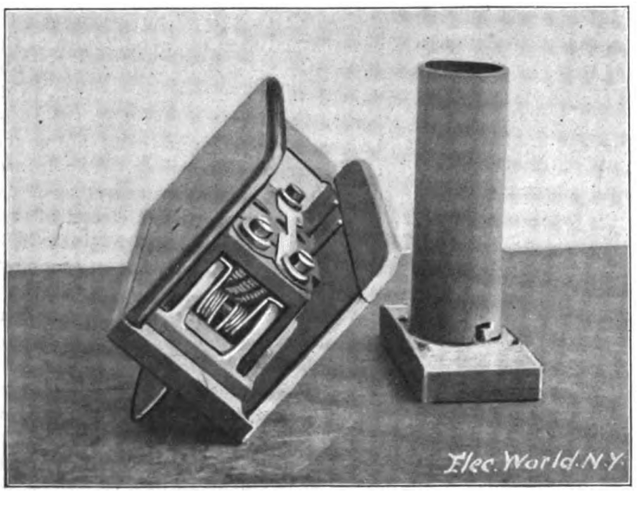

FIG. 2.—VIEW OF AN EXPULSION TYPE FUSE.

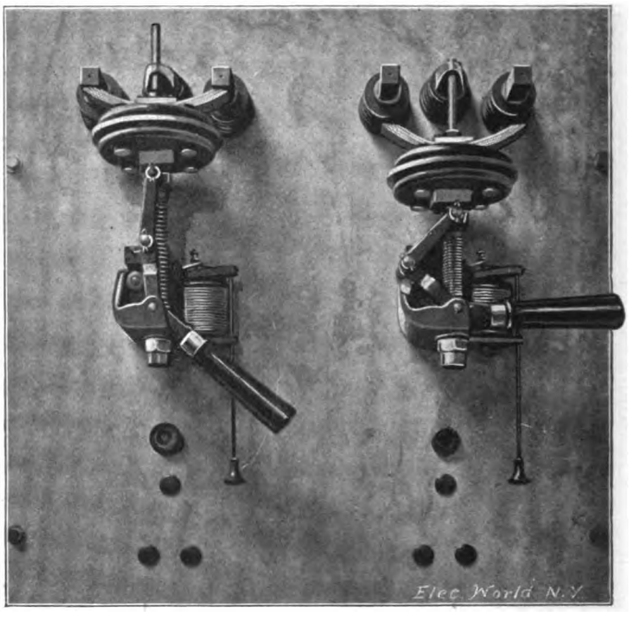

FIG. 3.—A SHUNTED FUSE CIRCUIT BREAKER.

With a fuse of this type, occupying a space of 6 in. by 3 in. on a switchboard, I have repeatedly broken 300 amperes at 13,000 volts without the slightest injury to the device.

Another switch or circuit breaker for the same purpose utilizes oil to extinguish the arc between the contacts. In this case the terminals are at the lower

Digitized by Google

end and are situated inside of vessels into which the fiber tubes project for a short distance. These vessels are partly filled with oil, the break occurring below its surface. In the switches of this type which we have designed the rods have been withdrawn from the tubes by a pneumatic cyclinder. The presence of the oil materially increases the breaking power of the switch and reduces the violence of the explosive effect when the circuit is opened.

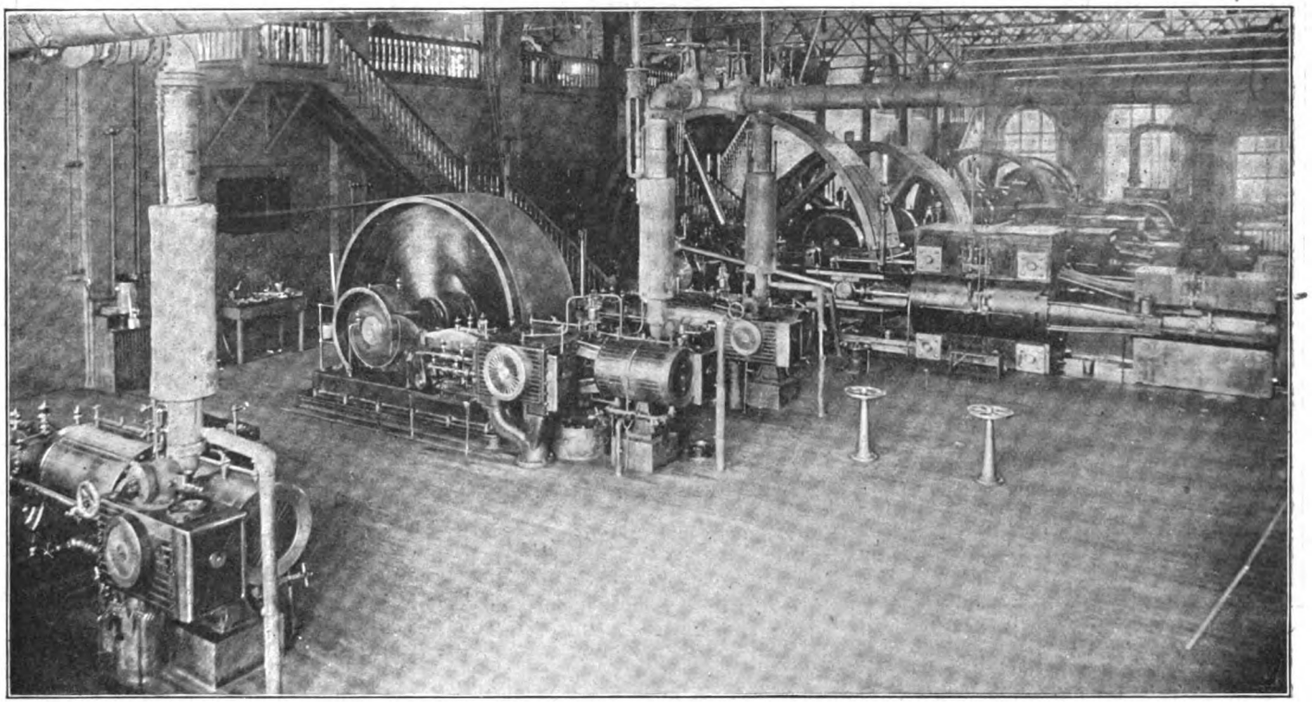
Fig. 3 shows a shunt fuse device that has been used in connection with circuit-breakers at Niagara Falls and elsewhere. The object of the design is to produce a fuse that can be placed in shunt with the circuit-breaker, to open the circuit after the main contacts are broken. It is, of course, desirable so to design such fuses that they can be very easily replaced. The fuse is placed in a slot in a long, wooden rod; this wooden rod is covered by a paper tube, and part of the wood is cut away at three points, so as to form air chambers inside of the paper tube. The rod is inserted in a long, wooden tube provided with vents that come opposite to these air chambers when the fuse is in place. The fuse is a small copper wire, and is attached to ferrules on the rod which make contact with springs at both ends of the tube. When the current is diverted into the fuse, which immediately volatilizes, the pressure in the chambers bursts the paper opposite the vents and the gas escapes through chimneys provided above the vents. The paper covering of the rod prevents the hot gas from getting into the interior of the tube; consequently the device can be used over and over again without any deterioration. These fuses have worked perfectly in parallel with circuit-breakers under the most difficult conditions that we have yet been able to produce.

---

The session of Thursday forenoon opened with a paper presented by Mr. H. M. Atkinson on

### ALTERNATING-CURRENT GENERATION AND DISTRIBUTION—CHANGES CONTEMPLATED IN ATLANTA.

We feel that we have a company in Atlanta that is a success. It has paid the people well who invested their money in it, and is doing so to-day. It is producing current at what we consider a low cost per kilowatt. With a successful record in the past, with everything running smoothly and satisfactorily, and with a bright outlook for a constantly increasing business, it is a hard thing to face radical and expensive changes, but the growth of our business forces us to act. We concluded early in the spring that we must have increased capacity to carry our load during the coming fall and winter. Two alternatives faced us: First, should we go on and add in conformity to our present equipment, or, second, should we depart radically from our past methods and, as it were, take a fresh start?



The station has seven large engines in the engine room, all of different sizes and all differing in many particulars, but all good engines of their kind. Most of these engines belt to counter shafting and the counter shafting belts up to thirty-seven small units. Three kinds, or perhaps more correctly four kinds, of current are generated and distributed.

Our dynamo room contains a number of small 1,000-volt alternators, three different kinds of direct-current series arc machines and four different kinds of power machines. The small alternators work at 125 cycles while the large direct-belted unit works at 133 cycles.

The different kinds of current that our station is generating to-day are as follows: 133-cycle, 1,000-volt, single-phase, 125-cycle, 1,000-volt, 500-volt direct current, 500-volt direct-current railway, 10-ampere direct-current arc, from three kinds of machines; and to do this work we are operating thirty-seven dynamos and generators and seven exciters. This complicated and varied equipment is the natural result of the state of evolution that we have been going through, and I do not think that anybody can be rightly blamed for it.

Our general plan for the future is to send the electrical output to the distributing wires—whether for direct-current, series alternating-current arcs, direct-current series arcs or any other kind of business—from large generating units of similar design and type working in multiple.

Taking up the question of periodicity, our field presents the possibility of a very large motor business. The lighting will fix the low limit of cycles, consequently we must use as low a cycle as possible for the best accommodation of our power business, but still high enough to handle our lighting service satisfactorily. Forty or forty-two cycles have been found to give unsatisfactory results on some classes of lighting, so that it is possibly wise to put fifty cycles as the lowest limit for lighting purposes. The manufacturers have chosen sixty as their standard. All the leading manufacturers build machinery and apparatus of this cycle, which is an added reason for selecting sixty. Special

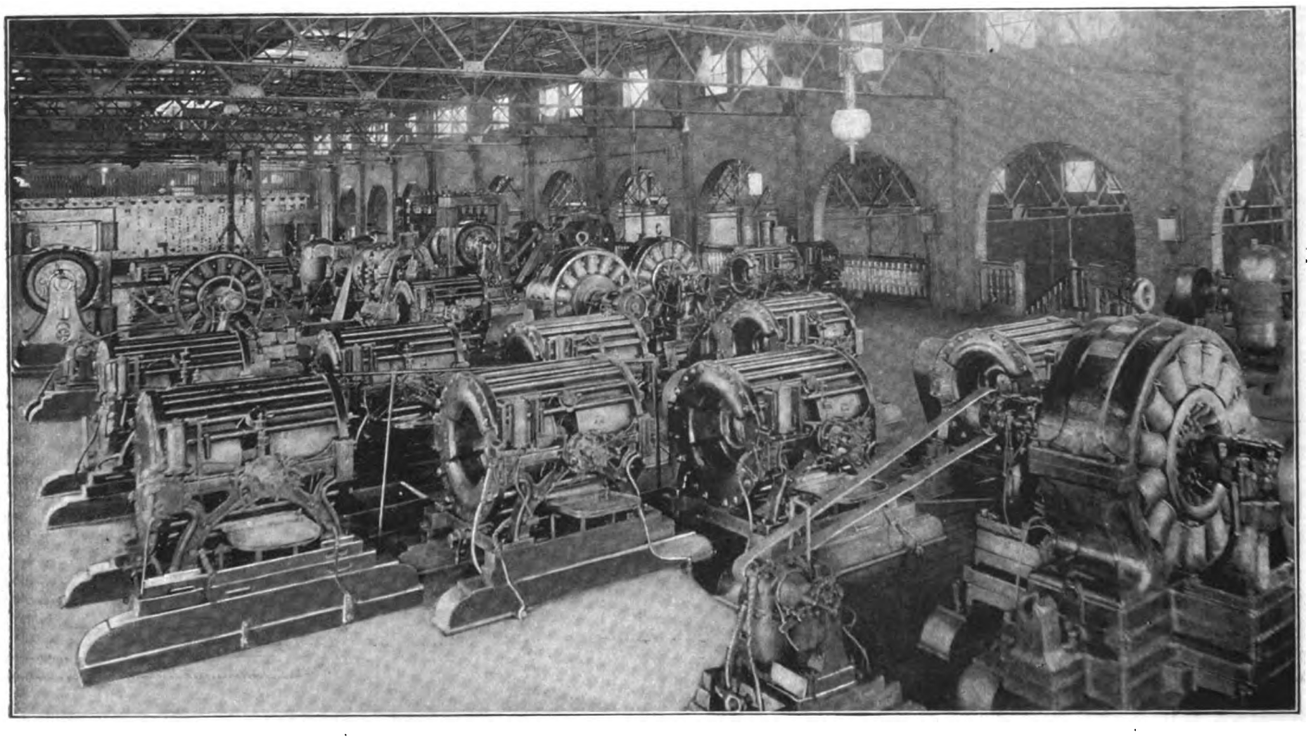
THE ENGINE ROOM OF THE CENTRAL STATION OF THE GEORGIA ELECTRIC LIGHT COMPANY, ATLANTA, GEORGIA.

Digitized by Google

machinery is objectionable on many accounts, and we should avoid it not only in our own interests but in the general interest of our business. Another point in favor of sixty is that it is the standard for arc lighting, consequently our decision is for sixty cycles.

Next comes the question of primary voltage. Our lighting center is not over one mile from our station, and will probably not be over a mile and one-half to our most distant motor, so that in either case the copper losses can be kept inappreciable without undue expense. Should work in time develop at greater distances, step-up transformers could be used in case the line losses shall figure greater than the transformer losses; therefore, we shall use 2,300 volts for the primary voltage.

Next we come to the phase of generator. This has been, perhaps, the hardest question to solve satisfactorily. There is not, perhaps, so much in the question of whether three-phase or two-phase is best, as a good many people make out. Be that as it may, we early reached the decision that single-phase, alternating current is the best system for our incandescent distribution, and that, whether two phases or three phases were employed in generating, only one phase finds its way to individual customers. Therefore, in order to get this single-phase, we must determine how we can get our primary current from our generator, still having in mind our decision to use a generator well adapted for a power business. A generator well adapted for power business must be two or more phase. Two-phase is simple, if all phases are distributed on streets for lighting only, but the majority of central-station men have a preference for the still greater simplicity of one phase under such conditions. Three-phase requires less copper for motor work. It is our intention to run lights from each phase in different sections of the city, and we must be prepared to run motors of any power from all three phases.



It seems best to us to employ the form of generator that is most economical in copper cost for motor distribution. This feature of our business has influenced us largely in our decision for three-phase generators. We intend to take the three primaries to our larger motors and to use induction regulators on each of two phases, regulating the third phase by the machine voltage and keeping this just right for the three-wire network that carries three-quarters of our incandescent-lighting load. A good point about this three-phase generator that we have selected is that it will, if we only load one phase, i. e., run it as a single-phaser, take 70 per cent. of its three-phase load on one phase at practically its three-phase efficiency. This is a case that probably never will occur in practice, but it is a point in favor of the generator.

Our street lighting at present consists of the equivalent of 870 9.6-ampere series arc street lights and 70 commercials. Our plan contemplates, of course, ultimately taking these lights off of three-phase generating units, either on the motor plan, using induction of synchronous motors and large arc machines, or "tubs" and series alternating arcs. For certain reasons we are undecided as to which of these plans we should use.

The unit we have just bought, of 400 kw. capacity, will take care of our day incandescent as well as any new power work, and would, with a larger unit of 1000 kw., which we contemplate buying, take care of the peak of our incandescent load as it stands at present. These two units, one of 400 kw. and the other of 1,000 kw., will be overloaded to the limit of safety as the business grows, and when we have gone as far as possible with them we shall add another large and duplicate set, running all three in multiple and dividing the load between them. We shall have a leeway of a good many months in which to decide whether to run our arcs from station motors or "tubs," and we think that these additional months will be of great importance to us in reaching a decision.

We shall use as large transformers as possible on each phase, keeping the number down to a minimum, and they will feed into our three-wire network. These transformers will be placed under ground in the central section of the city, and as the load drops off we intend that our trouble man, who is constantly on duty at our office within this district night and day, shall cut off unnecessary transformers. This will save the loss on such transformers as we are able to cut out for a large part of the twenty-four hours. We would not, perhaps, recommend this in all cases, but under our conditions it is practicable and will effect economy.

We hope to use single-phase motors of 1 h.p. and less. For heavy power work we intend to use induction motors running from motor transformers with the third wire brought across.

THE DYNAMO ROOM OF THE GEORGIA ELECTRIC LIGHT COMPANY.

---

Another paper of interest was that presented by Mr. Geo. W. Hubley on the following subject:

Digitized by Google

### TRANSFORMERS, IRON LOSS, ITS INCREASE, THE REMEDY.

It has been found in practice that transformers having initially low iron losses (within limits of specifications), after being placed in service, would show most decided increase. In most cases over one hundred per cent. increase, and in exceptional cases as high as three hundred to four hundred per cent. increase, within very short periods of service under normal conditions.

In fact the "fatigue" feature or large increase of iron losses in many transformers made their further use commercially prohibitive.

To illustrate the conditions of the question, the writer gives the following records of a few tests on various sizes of transformers, showing the increase of iron losses during periods of service:

| Capacity. | Initial Test. | | Second Test. | | P. Ct. Inc. | Third Test. | | P. Ct. Inc. | Total P. Ct. Inc. |
|---|---|---|---|---|---|---|---|---|---|
| | Watts. | P. Ct. | Watts. | P. Ct. | | Watts. | P. Ct. | | |
| 500 | 36 | 7.2 | 65 | 13 | 80.6 | 75 | 15 | 15.4 | 108.4 |
| 1,000 | 58 | 5 8 | 75 | 7.5 | 29 3 | 100 | 10 | 33⅓ | 72.4 |
| 1,500 | 60 | 4 | 97 | 6.5 | 61¾ | 120 | 8 | 23 7 | 100 |
| 2,000 | 75 | 3¾ | 125 | 6.1 | 66⅔ | 145 | 7¼ | 26 | 93 4 |
| 3.000 | 80 | 2⅔ | 133 | 4 4 | 66¼ | 150 | 5 | 12.8 | 87½ |
| 4,000 | 109 | 2 7 | 175 | 5¼ | 60 6 | 185 | 4.6 | 5 7 | 69 7 |
| 5,000 | 120 | 2.4 | 140 | 2 8 | 16⅔ | 145 | 2.5 | 3.6 | 24 8 |
| 7,500 | 145 | 1.9 | 167 | 2 2 | 15 1 | 190 | 2.6 | 13.8 | 31 |
| 10,000 | 190 | 1.9 | 250 | 2.5 | 31 6 | ..... | ..... | ..... | 31 6 |
| 12,500 | 218 | 1 7 | 238 | 1 9 | 9.1 | 315 | 2.5 | 32.4 | 44.5 |
| 25,000 | 523 | 1.3 | 530 | 2.1 | 64.1 | ..... | ..... | .... .... | 64 1 |

The above tests represent transformers of various types of manufacture during years of 1894, 1895 and 1896, and cover periods of service from 1894 to 1899. The actual service between tests vary from periods of six months to two years, but in most cases are tests made each consecutive year.

The following specification limits were adopted January 1, 1899, and all transformers must pass under initial conditions within specified limits, or be rejected:

| Capacity | Iron Loss. | | Regula'n Per Cent. | Capacity | Iron Loss. | | Regula'n Per Cent. | Capacity | Iron Loss. | | Regula'n Per Cent. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | Watts. | P. Ct. | | | Watts. | P. Ct. | | | Watts. | P. Ct. | |
| 500 | 35. | 7 00 | 3.00 | 3 750 | 90. | 2 40 | 2.50 | 15,000 | 210. | 1 40 | 2.00 |
| 600 | 36 | 6 00 | 3.00 | 4,000 | 90. | 2 25 | 2 50 | 18,750 | 225. | 1 20 | 2 00 |
| 1,000 | 45. | 4 50 | 3 00 | 5.000 | 110. | 2 20 | 2 25 | 20 000 | 240. | 1.20 | 2 00 |
| 1,250 | 45. | 3 60 | 3. 0 | 6,000 | 120. | 2 00 | 2 25 | 25,000 | 275 | 1 10 | 2.00 |
| 1.500 | 51. | 3 40 | 3 00 | 6,250 | 125. | 2.00 | 2 00 | 30,000 | 300. | 1 00 | 2 00 |
| 2 000 | 60. | 3 00 | 3.00 | 7,500 | 150. | 2 00 | 2.00 | 37 500 | 375 | 1 00 | 2.00 |
| 2,500 | 65 | 2 60 | 2 50 | 10,000 | 175. | 1.75 | 2 00 | 5 ,000 | 500. | 1.00 | 2.00 |
| 3,0 0 | 75. | 2.50 | 2 50 | 12 500 | 200, | 1 60 | 2.00 | ..... | ..... | ..... | ..... ..... |

Insulation test to be made by a series of make and break contacts, and one prolonged contact, as follows:

1. Between primary and secondary coils, 6000 volts a. c.

2. Between primary coil and core, 6000 volts a. c.

3. Between secondary coil and core, 1000 volts a. c.

Temperature test measured by thermometers placed in mercury cups in core of transformers. Increase above surrounding atmosphere on full load test of eight hours' duration must not exceed sixty degrees centigrade.

Fatigue.—Iron loss must not exceed ten per cent. increase above limits, as specified, within period of two years' service.

Overload.—Transformers must be guaranteed to stand overload of twenty-five per cent. above rated capacity, for duration of two hours, with temperature increase not to exceed sixty degrees centigrade above surrounding atmosphere.

General Guarantee.—Transformers must be guaranteed for two years' service against burn out from any cause (including lightning); providing same are under normal conditions of service.

Remarks.—The above specifications do not contemplate the use of oil in transformers.

It is probably unnecessary to state what the iron losses and their increase mean to the average central station, except to call attention to the fact that existing iron losses in transformers approximate from fifty to seventy per cent. of output of the average alternating station.

The question naturally arises, "What is to be done with transformers having abnormal "iron loss?"

The writer began some experiments in line of treatment of iron of old transformers, and after some time obtained most successful and gratifying results in this direction. However, no claims can be made at present writing of the permanency or resultant action that may occur by the methods adopted, as only time test will determine this point; but it is reasonable to expect the changes made in the character of the iron in transformers, so treated will prove itself more nearly constant and permanent than it was initially.

The method of treatment adopted is one of annealing the iron of transformers which show abnormal loss. The results have proven most gratifying, in all cases reducing the losses to their initial (or even better) records, and in no manner affecting other requisite qualifications of the transformer.

The work can be done readily and at an admissable low cost per unit, to make the work commercially within bounds, and a far better paying investment than any other plan that has been suggested or followed with the same object in view. In other words, it restores the transformer system, whether transformers are new or old type, to their original, or even better condition, as far as iron losses are concerned.

The "annealing treatment," as practiced, can be accomplished at so low a cost per kw. that it insures its success.

The following data of detail costs per kw. capacity have been computed from records of actual costs during period of experimental work.

| | Preparation. | Annealing. | Assembling. | Testing. | Total cost. |
|---|---|---|---|---|---|
| Average cost per K. W.... ..... | .092 | .106 | .618 | .084 | .90 |

However, the above costs cannot be taken as representative as they only represent the result of experimental work on transformers of various manufacture, type and capacity, and naturally these costs as given are considerably higher than will be found in practice.

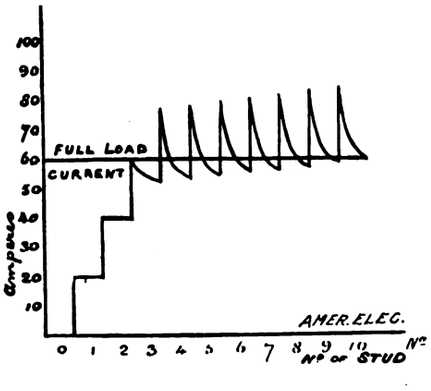
It can be liberally approximated that complete costs of "annealing treatment" will vary between twenty-two cents per kw. on 25 kw. size to $2.20 per kw. on ½ kw. size of transformer.

### GENERAL S. T. CARNES.

The president of the association elected for the coming year is General S. T. Carnes, of Memphis, Tenn. General Carnes has been for several years president and general manager of the Memphis Light and Power Company. He is one of the most prominent citizens of Memphis, having spent his whole life in that city. His title was gained through his position of Brigadier-General in the State of Tennessee.

## Among Our Foreign Contemporaries

**Novel System of Electric Bells.**—An interesting improvement, though not entirely new, is described in "L'Electricien." In this the bells, of which there are supposed to be a number in the installation, are made without the usual interrupter of the current and consists merely of the magnet, the armature, the clapper and the bell. The interruptions of the current are produced by a single interrupter, which is placed in the main circuit near the battery; this interrupts the current for any one or more of the bells. The advantages are evident, as the bells became cheaper and more easily maintained, as they require no adjustment and need not necessarily be made dust-proof. The interrupter is a small, simple affair enclosed in a box and placed where it is easily accessible.



**Energy Required for the Production of Calcium Carbide.**—While the important data for finding the amount of production or the cost of calcium carbide are those obtained in practice, yet the quantity of energy required theoretically is also of some interest. Mr. Gin, in "L'Eclairage Electrique," shows how this is calculated

Digitized by Google

and he finds that the quantity of energy necessary for producing a ton of the carbide is about 4260 kw. hours, which corresponds to a production of 5.63 kg., that is, 12.39 pounds of carbide per kilowatt per day. In a large plant in Austria it was found that the power required was 5.2 kg., which, if the theoretical figures are correct, corresponds to the very high efficiency of 92%. The amount of energy referred to is, of course, that generated in the furnace itself and not that of the original machinery.

**Regenerative Primary Battery.**—An improved form of the cell consisting of zinc and peroxide of lead, which gives as much as 2.5 volts, is described in the "Elektrotechnische Zeitschrift"; it is the invention of Messrs. Exner and Paulsen. In general this form of primary battery has been well known and has been a favorite subject for improvements owing to the very high voltage which it gives, thus utilizing the zinc to better advantage. There are, however, a number of objections, and it is these that the present inventors tried to overcome. The liquid, being sulphuric acid, is apt to attack the zinc on open circuit, and the peroxide of lead is also gradually attacked; acetic acid has been used, but it does not seem to be a success. In the present improvement a very weak solution of sulphuric acid is used, to which saccharic acid is added, besides some sulphate of mercury dissolved in ether. A weak gelatine solution is also added, which is claimed to protect the zinc on open circuit. This electrolyte, it is claimed, will not attack the peroxide of lead and the mercury salt, together with the gelatine, are said to protect the zinc. The battery is merely an improved form of what is known as the zinc-lead peroxide accumulator. It is regenerated by charging it with a current in the reverse direction, just like any other secondary battery.

**Calculating the Resistance for a Motor Starting Switch.**—A very simple method of calculating the various steps for starting resistance of a motor, if one is provided with a slide rule, is described by Mr. Hunt in the London Electrical Engineer. The calculation is, of course, divided into two parts, one the determination of the resistances in ohms necessary to produce a regular series of steps, and the other is to calculate the diameter and length of wire required to carry the respective currents without too much overheating. The conditions to be complied with are generally of the form that the current passing through the switch on the first knob must not exceed a certain amount and that when any succeeding sections are cut out the current must not increase to more than that amount; another condition is that the number of contacts must not be less than a given amount; from the first condition such a minimum is naturally involved. Up to the point at which the motor starts to run the calculation of the required resistance is merely an application of Ohm's law, that is, it is the quotient of the line voltage divided by the current which is allowed to pass. Unless there is a specification to the contrary, it is advisable to assume that the motor has to start with a full load, and in that case it will not start unless it receives the full load current. When the armature begins to move it generates a counter e. m. f. which tends to cut down the current, and as soon as the switch arm is moved to the next point there is a sudden rise again. The whole process is shown in the accompanying diagram in which the horizontal distances

represent the various contact points on the switch and the vertical distances the currents. The various resistances should evidently be so proportioned that the rise and fall of current shall take place over the same range for each contact point, assuming that the switch remains long enough in each position for the armature to run its full speed for that resistance. To fulfill this condition the resistance must be in a descending geometrical progression, a statement which he proves, on the assumption that the current is to fluctuate between a fixed maximum and minimum. The value of the resistances from the point where the motor starts is known, and the resistance in circuit for the last contact point is that of the armature only. All that is required, therefore, is to insert a number of geometrical means between these two extremes, and this is done most simply with the aid of the slide rule. To do this, find the two extreme values on the scale of a slide rule and then on a strip of paper divide the length between them into a number of equal parts, one more than the required number of means, and then read off the values at each division, which will give the required resistances. After having found these resistances it is necessary to calculate the length and diameter of the wire, which is done by means of the well known formula that for a given rise of temperature the current is equal to a constant multiplied by the square root of the cube of the diameter; the constant measured depending on the material and on the temperature, as also on the perfection of the ventilation, etc. It is, therefore, not possible to give any more than approximate values for this factor, and those he gives are as follows: For German silver from 1000 to 1500, platinoid 800 to 1300, Eureka 700 to 1100, tinned iron about 1100 to 2000.

**A 250-Volt Incandescent Lamp Installation.**—The introduction of high voltage incandescent lamps appears to be making better progress abroad than in this country. There is a small town in Italy called Arenzano in which a central station was installed last year, using the three-wire direct-current system with lamps of as high a voltage as 250, which is the highest of which we have read. This makes 500 volts between the outers, as as this is the same as used on most trolley lines it enables the two systems to be combined to advantage, at least in so far as using the same generators is concerned. A brief reference to this interesting installation is published in L'Electricien, but, unfortunately, very little information is given. The reason for using such a high voltage seems to have been that a water-power situated from 1 to 1.5 miles distant is used directly without transformation, and at the same time without a great loss in the feeders, or an excessive cost of copper. The advantage of the direct instead of the alternating current which would ordinarily be used in such an installation, is that no transformers are required and that accumulators may be used to store the energy. This latter is a very important feature in cases in which the water-power is comparatively small, requiring that some of the power be stored during the hours when little current is being used. To store the energy in an alternating current plant would require a complicated station for transforming the currents and this, besides being expensive, requires attendance. So far the station has been very satisfactory and no objections have arisen to the use of such high voltage lamps. If they continue to be a success it will enable the direct current to be used in many cases in which the alternating current is now necessary on account of the heavy cost of the copper feeders.

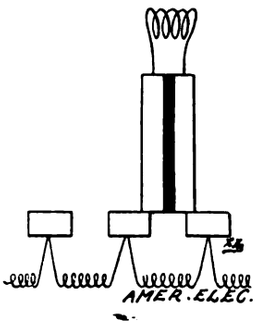
**Radiography.**—An Italian investigator states that a metallic reflector immediately behind a photographic film is beneficial in taking X-ray pictures, provided films and not glass plates are used. Two other Italian writers, however, claim that the metallic backing is beneficial in all cases, although less so with glass plates, and it is more important the harder the tube and especially when tocus tubes are used; it tends to avoid the fogging and want of contrast. With soft tubes requiring long exposure, it is not so necessary.

**Alternate Current Arc.**—What is probably the most prolonged, careful and complete investigation of the alternating current arc was recently made by Messrs. Duddell and Marchant and is described in a long paper, which they read recently before the Institution of Electrical Engineers in England. Among the many facts which they point out and conclusions to

Digitized by Google

which they arrive, the following may be of interest to those who are designing or using alternating arcs or are experimenting with them. Their investigations deal chiefly with the examination of the wave forms of the current, of the voltage of the arc, and the voltage of the dynamo. They found that at any instant the distribution of the voltage in the arc is similar to that in the direct current arcs. The efficiency of the alternating arc is effected by the amount of resistance in series with it. The effect of reducing the frequency of the alternating current is to greatly increase the actual time during which the current remains small in each period and also to increase the fraction of the period during which it is small. Accompanying this is a considerable increase in the maximum value of the current and a decrease of the frequency. The arc between solid carbons becomes very unstable below a frequency of 57; the arc between solid and cored carbons below 46, and between cored carbons at about 29, at which frequency the light was exceedingly unpleasant to the eye on account of the visible pulsations. The power factor was reduced by lowering the frequency. The light efficiency is increased by a reduction of the frequency, but there is a limit, owing to the instability of the arc at low frequencies. The quality of carbon used modifies the amount of the reactions of the arc on the form of the wave, but does not otherwise change the reaction itself. They also found that it is possible to considerably reduce the voltage necessary to maintain an arc of a given length and current, by treating the carbons with a potassium salt; they also think it is likely that the lower voltage and steady burning of arcs between cored carbons are largely due to the presence of a potassium salt in the core.

---



**High Efficiency Incandescent Lamp.**—Some time ago the startling news was published that Maxim, one of the pioneers in the invention of the incandescent lamp, had succeeded in improving the lamp so that there would be a saving of 25 per cent. in the number of watts required per candle. It now appears from London "Lightning" that not only has this efficiency been reached, but even exceeded, and that a factory for making these lamps at a rate of 6,000 a day, the largest factory of the kind in England, is in course of construction. The consumption of energy of these lamps is said to be only 2.8 to 3.0 watts per candle, as compared with 4 to 4.5 watts in the usual lamps. No further information is given at present, but more is promised soon.

---

**Transformer Cores.**—It has been found by several English investigators that pressure on the laminated iron of the core of a transformer increases the hysteresis loss very considerably. A pressure of 2200 pounds per square inch, for instance, increased it about 53 per cent. Mr. Scott, in the London "Electrician," therefore points out that it is bad practice in building up transformers to tighten the bolts which hold the plates together, any more than it is absolutely necessary for good mechanical construction. The several makers of transformers have now adopted a construction in which the plates can expand and contract. He also considers that punching and hammering the plates is a very objectionable method, as it affects the iron losses; he strongly recommends changing the design so that the plates can be cut instead of being punched.

---

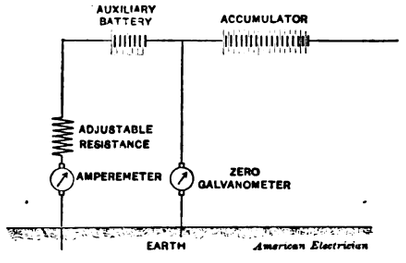
**Improvement in Step-by-Step Resistances.**—In step-by-step resistances, such as are used for regulating field magnet currents for motor starting, switches, etc., it is often desirable to diminish the amount of resistance in each step so as to be able to adjust more accurately. A method for doing this without increasing the number of contact points was recently described in the "American Electrician," but since then another method differing slightly from it was shown in "L'Electricien" by Mr. Goichot. It consists simply in the use of one movable coil secured to the movable arm, and having its ends terminate in blocks or strips which come in contact with the knobs of the usual resistances. When its two ends are connected to two contact points of the resistance, as shown in the adjoining figure, it is evident that the additional coil will be in multiple with one of the regular coils; when moved slightly farther to the right or left the additional coil will not be in circuit. The arrangement thus enables all the other resistances to be obtained, besides one more step between each of the others, thus practically doubling the number of steps.

---

**Automobiles in Germany.**—A large company in Germany is making the lower or working parts of various forms of automobiles on which different kinds of carriage bodies may be placed as desired. Their standard sizes are described and illustrated in a recent issue of the "Elektrotechnische Zeitschrift," and as the company seems to have made a thorough study of the problem, the conclusions that they have reached may be of some interest. For an omnibus the trucks have two motors and the hind wheels are used as drivers; the front wheels are knuckle jointed and ball bearings are used on all of the wheels. The different speeds are obtained by dividing the battery into two halves and connecting these variously in parallel or in series with the two motors which are also parallel or series. In braking, energy is restored to the battery, thus saving considerable wear on the brake blocks and tires. On the roof of the omnibus are movable contact bars such as are frequently used on German trolley lines, which enable the omnibus to be charged by simply passing under two trolley wires. There are 44 cells to the battery and one charge is supposed to run 12 miles, but it is recommended to recharge for 15 minutes at the end of about every five miles. The total weight of an omnibus for 18 passengers is 7700 pounds. Another form of truck is intended for delivery wagons, pleasure carriages for a number of passengers, for the mail, etc., or in general for a load of 1000 to 2000 pounds. This contains only one motor, the hind wheels being driven as before. The batteries are also connected in parallel or series for regulation of the speed; the capacity of the accumulator is enough for a trip of about 18 miles. It appears that the wheels of none of these are provided with rubber tires. A third form of truck is for the ordinary city carriage for three to four persons besides the driver; it has two motors and the controller enables it to be run at four speeds, but the battery is not divided into two parts. The maximum speed is 12 miles per hour, and the weight of the unloaded carriage is 2400 pounds. Some tests made with an omnibus weighing 5.1 tons showed a consumption of 80.5 watt hours per ton kilometer. In another, over a longer run, the consumption was 77.2 watt hours per ton kilometer.

---

**Quick Method of Calculating the Weights of Conductors.**—An interesting method of rapid calculations and more especially comparisons between the costs of different materials for the line, such as copper, iron or aluminum, is described in "L'Industrie Electrique." The mass, that is, the weight, of a line of given length and resistance, is proportional to the product of the resistivity (that is, the specific resistance) and the density of the material, both of which are physical constants. This product for iron is 78, for copper 14.24, and for pure aluminum 7.54; the weight of metals for lines made of these materials will therefore be in the proportion of these figures. If, for instance, the cost per pound of aluminum is about double that of copper, then the cost of the line will be equal for these two materials, because 14.24 is about double 7.54; when the cost of aluminum becomes less than that, it will be the cheaper of the two metals. The actual weight of a line in kilograms is determined by the following formula, in which L is the length going and returning, in meters, R the total resistance in ohms, r the specific resistance in microhms per cb. cm. and D the density:



$$W = \frac{L^2 rD}{R \times 1000}$$

For commercial copper at 15°C the product of rD may be taken to be equal to

Digitized by Google

16 and the value of R is readily determined from the allowable loss in the line.

**Measuring the Insulation Resistance of a Large Number of Accumulators in Series.** - If it may be assumed that a battery of a series of accumulators has only one fault in the insulation resistance between it and the earth, it is a simple matter to determine this, as it is only necessary to connect a voltmeter first between one pole of the battery and the earth and then between the other and the earth, and from the deflections and the resistance of the voltmeter, the insulation resistance may then be calculated. If, however, there are, as is generally the case, a large number of points of leakage, this method fails and it is for this case that Mr. Liebenow in the "Elektrotechnische Zeitschrift" describes a very simple method of measuring the total insulation resistance. The battery must first be disconnected from the circuits; an ampere meter is then connected between one pole and the earth and another measurement

made between the other pole and the earth; the insulation resistance is then equal to the voltage of the whole battery divided by the sum of the two currents which were measured, regardless of their signs. If greater accuracy is required, or if the insulation resistance is very high, he suggests using a higher resistance ampere meter and a small but well insulated auxiliary battery which is connected in series with the main one, so that the voltages are added to each other. The resistance is then calculated in the same way except that twice the voltage of the auxiliary battery is added to that of the main battery; and that from the resistance, that of the ampere meter must first be subtracted. It is necessary in this case that twice the voltage of the auxiliary battery is greater than the product of the resistance of the galvanometer by the sum of these two currents. If the resistance of this auxiliary battery cannot be neglected and is not known, or if that of the ampere meter is not known, he suggests the method shown in the adjoining illustration. A second galvanometer, which is a mere zero instrument like that used in the Wheatstone bridge, is connected as shown and an adjustable resistance is added in series with the ampere meter, it being adjusted in each case so that the deflection of the other galvanometer is brought down to zero. This test is repeated for both ends of the battery, and the insulation resistance is then as before equal to the voltage of the main battery only, divided by the sum of the two curents read in the ampere meter. This method is said to be quite accurate, but it is necessary that the voltage of the auxiliary battery is sufficiently great to bring the other galvanometer to zero; the voltage required will be less the greater the insulation resistance. To provide against injuring the instrument in case there is a dead ground in the battery, each of the battery poles should first be grounded through a fuse (each separately, of course), before the ampere meter is in circuit.

**Zinc Plating.**—It may not be as generally known as it ought to be that a coating of zinc on iron acts quite differenly than when the iron is plated with other metals, such as nickel, silver or copper. Unlike these other metals, zinc protects the iron electrically by virtue of the fact that in the presence of moisture a galvanic couple will be formed between the zinc and any exposed parts of the iron, which will cause hydrogen to be formed on the exposed iron, and this tends not only to keep rust from forming, but will also reduce any rust which may have been formed. To successfully plate iron with zinc is, therefore, much more important than to nickel plate it, but unfortunately, it is much more difficult. The following receipt from the "Zeitschrift fuer Elektrotechnik" may therefore be of interest: The bath should have a specific gravity of 1.135, or contain about half a pound of zinc sulphate per quart of water. Its current density should be about 0.1 to 0.2 amperes per square inch, and the solution should be kept stirred. The articles must be very carefully cleaned before plating, and the bath should be replenished with a mixture of zinc dust with about twice its weight of powdered coke, suspended in a bag.

**Accumulator.**—Great claims have been made for an accumulator manufactured in Italy in which the porosity of the oxides is produced by mixing with the oxide a material called ulmate of ulmine, which is made by boiling sugar in dilute sulphuric acid. This is an inert material which is gradually oxidized and dissolved, thus leaving the active material porous. It is used in the Pescetto accumulator, which is briefly described in the London "Electrical Review."

**Application of Electricity to the Manufacture of Glass.**—What seems to be a novel and practical application of the electrical furnace is described in our French contemporary, "L'Electricien." The process has been patented by Mr. Kroll, and is now used in an experimental plant in the city of Cologne, where the results are said to be very satisfactory. He uses an electric arc furnace with which the raw materials for the manufacture of glass are fused. The great advantage of the method is that a very small installation will replace the usual large furnaces and that it requires but 15 minutes to heat a charge which formerly required 30 hours of heating; in spite of the various transformations which the energy has to undergo, it is said that there is a very large saving in coal, which is doubtless due to the fact that the heat is so localized that the losses by radiation and conduction are very greatly reduced. It takes such a short time to fuse a charge that this furnace may be started or stopped at any time without great loss, instead of having to keep up the fires when no work is going on. The material produced is also said to be purer, as it is not contaminated with the ashes and particles of coal which get into the glass by the ordinary process.

**Temperature of the Bunsen Flame.**—Mr. Beikenbusch has measured the temperature of the non-luminous Bunsen flame by a new electric method and found it above 1820°C. His method was rather ingenious, as it eliminates errors existing in the methods heretofore used. He employed a thermo-couple, heating it by an electric current until it had the same temperature as that of the flame, so as to eliminate errors due to radiation and convection; the temperature of the thermo-couple for that same current is then measured in a vacuum. The general idea of making the two temperatures equal, and then measuring one of them by a more convenient method than measuring the original one directly, is a good one and may be applied in other cases to advantage.

**Efficiency of Man as a Machine.**—The human body when alive is, strictly speaking, a machine, converting the energy of the food into mechanical and other forces of energy, and the efficiency of this conversion is a matter of considerable interest. The problem of measuring it is necessarily an extremely complex one, as the value of the energy in the food is to be determined besides that in what leaves the body, including, for instance, the heat in the air of the breath, the vaporization of the moisture, etc. What seem to have been very painstaking researches of this difficult problem have recently been conducted by Dr. Marcet and Mr. Floris in a British Royal Society paper, a very brief acount of which is given in the London "Electrician." These seem to show that in general the efficiency of man as a human machine is a little less than 20%. This, as will be seen, is far superior to that of the steam engine together with its boiler, and also much higher than that of an ideal Carnot heat engine when it is working between the limits of temperature found in the human body. If man were simply a heat engine his vital organs would have to operate at temperatures like those in a gas engine in order to develop such a high efficiency. The mechanism by which this action takes place seems to be still obscure, the only thing known being that it is a sort of physico-chemical engine which differs from any form of mechanical engine which we know of.

# NOTES.

**Mr. Charles F. Brush,** of Cleveland, O., has received from the American Academy of Arts and Sciences in Boston the award of the Rumford medal for the development of arc lighting.

**A Rheostat Museum.**—The Cutler-Hammer Manufacturing Company, Chicago, is making a collection of rheostats and already has a number of curious specimens. To make this collection more complete the company offers to replace 10 starting rheostats over five years old and under 10 h. p. with its latest type of apparatus.

**Railway Feeders of Aluminum.**—The North Western Elevated Railroad of Chicago has closed a contract for 150,000 lbs. of aluminum for use as feeders to its third-rail system. The conductors will be placed in a wooden box or trough covered by the board walk between the tracks, and will be supported on vitrified clay blocks placed 9 ft. apart.

**Electrical Supplies for Our New Possessions.**—The demand has arisen for a catalogue of electrical appliances and supplies printed in Spanish for use in the newly acquired territory of the United States. Any one issuing such a catalogue or contemplating the publication of one would confer a favor upon the readers of the American Electrician by notifying the editor of that fact.

**The Telephone in Japan.**—The Imperial Diet of Japan has voted to expend $12,800,000 within the next seven years for the improvement of the government telephone system, and a young electrical engineer, Rinja Nakayama, has been sent to the United States for the purpose of investigating the latest inventions and improvements along that line. Japanese electricians will do all the work.

**An Automobile Club.**—About fifty owners or prospective owners of automobiles met in New York City June 7th, and effected a temporary organization of the Automobile Club of America. The purpose of the organization is to advance the interest of automobile owners by providing quarters for the vehicles, establishing proper regulations for the use of automobiles in the city and country, and exerting every influence in favor of good roads.

**An Automobile Repair Wagon.**—The Consolidated Traction Company, Pittsburgh, Pa., is about to add to its equipment an automobile emergency wagon, built by the Pope Manufacturing Company. The new wagon will have a storage battery that will give it a mileage of not less than 15 miles at an average speed of 10 miles per hour on ordinary city streets where the average grade does not exceed 1 per cent., and where the maximum grade does not exceed 10 per cent.

**The Consolidation of Many Lighting and Traction Companies in and Around Pennsylvania.**—The United Power & Transportation Company, although less than three months old, has acquired by purchase no less than fifteen companies all in operation furnishing electric light or power or operating street railways, having a total mileage of 250 miles, all in or near Lebanon, Reading or Philadelphia, Pa., Wilmington, Delaware, or Trenton, N. J. The authorized capital stock of the company is $12,500,000, of which sum 10 per cent. has been paid in.

**A Weekly Street Railway Paper.**—The first issue of the weekly news edition of the "Street Railway Journal" is that dated June 17th, 1899. The new publication will be devoted to news items which can thus be given more promptly and more fully than they can be in the monthly publication of the same name. The Weekly Bulletin of Advance Information, hitherto issued to advertisers and manufacturers, has been merged into the new weekly edition and the latter will be sent regularly to all American subscribers and advertisers of the monthly publication without extra charge.

**The New Structure of the Chicago Telephone Company.**—The addition to the building which the main exchange of the Chicago Telephone Company now occupies will more than double the size of the structure. The present building is 7 stories in height and the new one will be carried up to a height of 8 stories, the upper story being carried over the old building. This story, 80x90 ft. in dimension, will be used for the main operating room. In addition to its 12 exchanges in Chicago, the company now operates telephones in about 140 towns in the district immediately surrounding the city.

**A Name for the Electric Vehicle.**—The "Electrical Review" has announced the winning name in its prize contest for a name for electrically driven automobiles. The winning name is "electromobile" and was suggested by Mr. E. E. Ries. A few of the 400 names sent in are as follows:

| | |
|---|---|
| Accelawatt, | Autovolt, |
| Equine-nit, | Elecar, |
| Bacrotom, | Pacolet, |
| Automo, | Franklin, |
| Aut, | Automote, |
| Faraday, | Chevaless, |
| Autopropelectric, | Moby, |
| Electragon, | Plantemobile, |
| Trolley-Ho. | Electrola, |
| Moto, | Antihorse, |
| Locomobile, | Voltcar, |
| Telecar, | Quatrecycle, |
| Electrapel, | Odomotor, |
| Autogo, | Autema. |

**More Niagara Power for Buffalo Street Cars.**—It is reported that the Buffalo Street Railway Company will spend $1,000,000 on improvements this year. Of this $350,000 will be spent for electrical machinery for electrical transformers, converters, etc., for five new transforming stations in which the high tension polyphase Niagara power will be transformed to 550 volts direct current. The company now is taking 2,000 h. p. from Niagara, the balance being generated at the Niagara street steam plant. The new stations will do away entirely with the need of steam generation and will reduce greatly the copper losses of distribution.

**The Advance of the Nernst Lamp in Germany.**—From a lecture given by Dr. Nernst in Berlin it appears that Nernst lamps are now being made by the Allgemeine Elektricitats Gesellschaft in 25, 50 and 100 c. p. sizes with a life of about 300 hours and an efficiency of 1½ to 1¾ watts per candle power. Experiments are also being made with lamps of higher candle power. The wholesale manufacture of 110 and 220-volt lamps will be commenced as soon as the new works, which are being erected by the company for that purpose, are completed. The German patent office has dismissed all petitions against the validity of the Nernst lamp patents.

**The Use of Electric Traction in the Baltimore & Ohio Tunnel.**—The famous equipment of heavy electric locomotives for tunnel service on the line of the Baltimore & Ohio Railroad through the city of Baltimore, Md., is not used to nearly the extent that was originally anticipated. The delay caused by coupling and uncoupling the electric locomotives is so serious that practically all the passenger trains and about 25 per cent. of the freight trains are pulled through the tunnel by the steam locomotives, the steam and gases from which are not as serious as was anticipated. The result is that the generating station has considerable surplus power, which is sold to the surface railways.

**Street Railway Consolidation in Chicago.**—On June 2d the stockholders of the North Chicago and the West Chicago Street Railway Company authorized the lease of their properties to the New Chicago Union Traction Company; the latter is also considering the leasing of the Consolidated Traction Company, which operates the outlying surface feeder lines of the North and West sides. The elevated roads will probably also be taken over later. The new company has been incorporated with an authorized capital stock of $32,000,000, of which $12,000,000 is preferred and has already been subscribed. There remain outside of this consolidation the Chicago City, the South Chicago, the Calumet and the Englewood companies.

**Electric Cab Service for the New York Central Railroad.**—George H. Daniels, general passenger agent of the New York Central & Hudson River Railroad, has determined to establish an electric cab and carriage service at the Grand Central Station in New York City. A charging station and a general repair shop for the electric vehicles will be built in the station. The cabs are to be owned and operated by the railroad company. One hundred will probably be installed as soon as the station is completed. It is said that the railroad company has found it impossible to maintain a first class horse cab service at the prevailing rates of fare.

**The National Electrical Code and Supplement.**—The Electrical Bureau of the National Board of Fire Underwriters has issued an edition of 1899 of the rules and requirements of the National Board for the installation of wiring and apparatus for electric light, heat and power, as recommended by the Underwriters' National Electric Association. The Bureau has also issued a supplement to the code, containing a list of electrical fittings that have been examined and approved by the Underwriters' National Electric Association for use under the rules and recommendations of the code. Copies of these may be obtained from Mr. Wm. H. Merrill, Jr., Electrician of the Bureau, 67 E. 21st Street, Chicago, Ill.

**The Survey for the German-American Cable.**—The preliminary surveying work over the proposed course of the cable between Germany and the United States via the Azores was practically completed June 10th, when the British cable ship "Britannia" arrived in New York harbor after having taken soundings between Fayal and Sandy Hook. The proposed cable will start at Emden, touch at Punta Delgada in the Azores, and probably end at Coney Island. By way of the Azores it will give an alternate route to Southern Europe through the Portuguese cable now operating. Its cost will be in the neighborhood of $5,000,000. The length between the Azores and New York will be about 2300 miles.

**Electric Vehicle Companies for Every State and Territory.**—The plans of the electric vehicle syndicate are gradually unfolding. Recently an important step was taken in the organization of seventeen companies under New Jersey laws, sixteen of them with a capital of $100,000 each, and one with a capital of $6,000,000. The latter company is to operate in Washington, D. C., while the others are to be distributed in Tennessee, Georgia, Ohio, Kentucky, New Jersey, Louisiana, Delaware, California, Michigan, Minnesota, Iowa, Maryland, Wisconsin, Indiana, Missouri and Virginia. It is said that the capital stock of these sixteen companies will soon be greatly increased and that similar companies will be organized in every State and Territory of the Union.

**A Notable Meeting of English Engineers.**—The second biennial engineering conference of the Institution of Civil Engineers was held in London, June 7th, 8th and 9th. The proceedings were inaugurated by the address of the President, now Sir W. H. Preece, Knight Commander of the Bath, who was recently knighted on the occasion of the Queen's eightieth birthday, in honor of his long and valuable services as the chief engineer of the British Post Office, from which position he has recently retired. Several valuable papers were presented before the electrical section of the conference. Many excursions were arranged for the members attending the conference and the headquarters of the Institution were filled with the usual large number of exhibits.

**A Merger Company in the Electric Railway Field.**—Closely associated with, and, in fact, a part of the combination of interests commonly known as the Whitney, Widener, Elkins syndicate is the American Railways Company, formed some months ago, the purpose of which is to purchase and operate electric railways throughout the country. During the last month the company has purchased the properties of the Consolidated Traction Company and of the Pittsburgh United Traction Company, both of Pittsburgh, Pa., thus bringing these companies into close communion of ownership with the street railway systems of New York, Chicago and other cities, owned by the members of the syndicate. The American Railways Company is also alleged to have purchased the railway and lighting systems of Springfield, Ohio, as well as other smaller properties of the same kind in New Jersey. Rumors come from other cities, notably Baltimore, of pending transactions of the same nature.

**The Largest Incandescent Lamp Ever Made.**—It would seem at first sight ridiculous to construct incandescent lamps of a candle power comparable with that of

A 5000 C. P. INCANDESCENT LAMP.

arc lights, owing to the superior economy of the latter, but for one particular purpose the incandescent lamp is far preferable. That purpose is light house illumination, in which the superiority of the incandescent is its greater fog penetration, the yellower rays of the glowing filament being dampened out and absorbed to a much less extent than the rays of an arc light. The Bryan-Marsh Company has on this account been experimenting on large lamps, the largest of which is one nominally of 5000 candle power, which was exhibited at the Electrical Show, and the magnitude of which can be judged from the accompanying reproduction of a photograph which is reprinted from the "Imperial Lamp Gazette." The lamp is of the standard double-filament type like the smaller Imperial lamps, the two filaments being in parallel with each other and each taking the full 236 volts. The economy was about 3 watts per candle, the total consumption of power being, therefore, some 15 kilowatts, requiring a current strength of over 60 amperes. The lamp was exhibited but three nights when it burnt out, owing probably to the intense heat to which the glass of the neck of the bulb was subjected. Owing to the fear that the filament would droop, the lamp hung in a position the reverse of that shown in the illustration, and the heat was very intense at the base, probably softening the glass, which then collapsed due to atmospheric pressure. A larger bulb in an upright position would eliminate this difficulty. The cost of construction and erection of this single lamp was over $1000.

**The Coming Electrical Show in Chicago.**—With the vigorous enthusiasm characteristic of Chicago, the contemplated expansion of the exhibit features of the coming street railway convention is receiving a hearty support which promises to make it a notable electrical exhibition. As mentioned in the last issue of the American Electrician, the National Exposition of Electrical Arts Company has been incorporated to handle the show, and the active way in which the company is pushing its work is already apparent. The exposition will be held at the Tattersalls Building on 16th and State Streets from September 25th to October 9th. The location is a convenient one and the building is admirably suited for the purpose, its floor space being 150x280 ft. Work has been already undertaken for the preparation and decoration of the building for the occasion. The date was selected partly on account of the large number of people who will visit Chicago for the purpose of seeing the Fall festivities as well as the government celebration of the laying of the cornerstone of the new Post Office. A special effort will be made to obtain exhibits of automobiles and an elevated track 300 ft. long will be provided for exhibiting the same in operation. The building will be illuminated with some 5000 incandescent lamps for the evening sessions. The electrical operating companies in Chicago, notably the Chicago Edison Company and Chicago Telephone Company, have exhibited their usual public spirited interest in the affair and will take an active part in assuring its success.

**The Consolidation of Electrical Interests in Washington.** — The two electric light companies and most of the street railway companies in the District of Columbia have been absorbed by the purchase of a controlling interest in their capital stock by the Washington Traction & Electric Company. The street railway companies are as follows:

| | Miles of track. |
|---|---|
| Metropolitan Railroad Company (electric conduit) | 22 |
| Columbia Railway Company (cable) | 6 |
| Anacostia & Potomac River Railway Company (horse) | 15 |
| Georgetown & Tennallytown Railroad Company (electric) | 10 |
| Brightwood Railway Company (electric) | 11 |
| Washington, Woodside & Forest Glen Railroad Company | |
| Washington & Great Falls Electric Railway Company (electric) | 10 |
| Washington & Rockville Railway Company | |

The companies operating, but not in this consolidation, are the following:

| | |
|---|---|
| Capital Traction Company (electric conduit) | 22 |
| Washington, Alexandria & Mt. Vernon Railway Company (electric) | 26 |
| Washington, Arlington & Falls Church Railway Company (electric) | 10 |
| Washington & Glen Echo Railroad Company (electric) | 12 |

The consolidated company has opened subscription books for $12,000,000 of its authorized issue of $20,000,000 of 4½ per cent. bonds. (The authorized stock is $12,000,000.) The report of President H. H. Vreeland and Chief Engineer F. S. Pearson of the Metropolitan Street Railway Company of New York City estimates the combined revenue from the lighting and railway properties at about $2,400,000, and within three years at least $3,000,000 per annum. In the official prospectus the operating expenses are estimated at $1,150,000, leaving with the above mentioned estimated gross income, a net income of $1,250,000. The total fixed charges are given as $887,500. The advantages of the consolidation in the way of giving the suburban companies through routes to the business districts, combined with the improvements, extensions, mechanical and electrical consolidations and development of water power proposed, should make this merging of interests a highly profitable one.

---

**The Consolidation of Electric Traction and Lighting Companies in Eastern Massachusetts.**—It is now officially announced that some 33 street railway and lighting companies operating in Eastern Massachusetts will be consolidated under one association to be known as the Massachusetts Electric Companies. The concerns consolidated operate the greater part of the street railway mileage north of Boston as far as Nashua, New Hampshire, Newburyport and Gloucester, Mass., and south as far as Fall River, Mass., Newport and Providence, Rhode Island. The street railways have a total of 649 miles of track and operate 1426 cars from 18 power stations, with a total rated capacity of 28,000 h. p. Two electric lighting companies are also included. The consolidation will be in the nature of a trust, a board of 15 trustees, appointed by the certificate holders, holding the title to the controlling interests in the stock of the various existing companies. The Massachusetts Electric Companies has been capitalized at $24,000,000, half of which is in 4 per cent. cumulative shares. The net income of the properties for the last fiscal year applicable to dividends on the shares of the association was $733,000.

---

**A New Gas Burner.**—From time to time improvements are brought out in gas lighting devices with widely heralded claims that they will drive electric lighting out of use. The latest is being exploited by the Kern Incandescent Gas Light Company, which has, during the last few days, opened a subscription list of $3,500,000 of its 7 per cent. cumulative preferred stock. The total share capital of the company is $12,000,000, and it appears from the list of prominent bankers and others among its directors that the company is to be a very strong one financially. The device which the company is formed to exploit is an improved burner constructed under the patents of Otmar Kern, which is claimed to give, with incandescent mantles, about twice the candle power obtainable with the ordinary Bunsen burner used in Welsbach lamps. The improvement consists in a construction such that the whole supply of air for the consumption of the gas in the proper ratio is always introduced at the bottom of the burner, no adjusting device being used and no auxiliary air supply to the flame above. The burner also has a grating for intimately mixing the gas and air and a means for partially heating the mixed gases on the regenerative principle before they are consumed. These devices, it is claimed, give about 40 c. p. with a 1-ft. burner and 27 c. p. gas. The officers of the company claim that they have available means of protecting their mantles equal to the Welsbach Company's broadly patented protection by means of a stiffening substance which can be burned off.

---

**The Independent Telephone Convention.**—The third annual meeting of the Independent Telephone Association of the United States was held at the Auditorium Hotel, Chicago, on June 26th, 27th and 28th. The following subjects were on the programme: Paper by S. P. Sheerin, of Indianapolis, president of the New Long Distance Telephone Company, of Indiana. Subject: "Value of Long Distance Toll Lines." Paper by C. L. Boyce, manager of the Citizens' Telephone Company, of Grand Rapids, Mich. Subject: "Operation and Maintenance." Paper by Maxine Reber, electrical engineer, of Cuyahoga Telephone Company, of Cleveland, O. Subject: "Essentials of Telephone Construction." Paper by Hon. Harry D. Critchfield, counsel for the United States Telephone Company, of Ohio. Subject: "Development of the Independent Telephone Business."

---

**The Electrical Equipment of the Machine Shops of the New York Navy-Yard.**—The United States Naval Department has drawn up the specifications for a power plant for the new shops of the Navy-Yard in Brooklyn, in which power will be distributed electrically on lines remarkably advanced for a government installation. The generating equipment will consist of three 600 h. p. vertical, cross-compound engines, each direct coupled to a 400 kw. 25-cycle alternator, mounted between the cranks. It is explained that this frequency has been adopted as it is that of the Kings County Light & Power Company, indicating that a break down connection may be contemplated. The machines will generate current at low pressure, 220 volts, two-phase, which will be distributed without transformation to the shops, the feeds being short, as the shops will be enclosed by a rectangle about 350x500 ft. in size. The electrical distribution will be complete, each tool requiring more than 5 h. p., having its own independent multiphase motor. Thirteen electric cranes will be installed.

---

**The Failure of the Illumination at the Last Great Prize Fight.**—At the Fitzsimmons-Jeffries fight at Coney Island on June 9th an attempt was made to illuminate the scene to a sufficient brilliancy by means of reflecting arc lamps to obtain living-picture films of the various rounds. Twenty-four reflecting lamps were hastily improvised, each intended to consume about 60 amperes. These were arranged on the edge of a platform surrounding the ring and some 30 ft. above its level, the beams being directed downward upon the scene to be illuminated. The work was undertaken very hastily, a temporary generating plant being necessary to give the required power, and at the last moment it was found that it would not carry the load. Less than half the lights were illuminated and those only to a low intensity. The attempt to obtain films was a total failure, causing a loss of many thousands of dollars.

---

**The Consolidation of Electrical Interests in Connecticut.**—The Connecticut Lighting and Power Company has, through agents, purchased the properties of the Central Railway and Electric Company of New Britain, the Waterbury Traction Company, the Naugatuck Electric Light Company, the Norwalk Gas and Light Company and the South Norwalk Electric, the Greenwich and the Housatonic Power Companies. The water-power rights owned by the last named company will be developed for the delivery of 30,000 h. p. to the lines of the various companies named, the power being so located that it can be readily and economically delivered to all the cities in the southern and western portions of the State of Connecticut. The purchases, together with the improvements and alterations contemplated, will represent an expenditure of about $6,000,000. Mr. A. M. Young, recently President of the National Electric Light Association, is a prime mover in the scheme.

### The Electric Light Convention.

The twenty-second annual meeting of the National Electric Light Association passed off in New York City, May 23d, 24th and 25th, with its usual precision, dignity, absence of confusion and general success. The attendance was large, about 300 names being registered. The growing attention to the papers and discussion was continued, the electrical exhibition was an attractive side show, the weather was ideal, the automobile ride proved a most enjoyable novelty, and crowning all was the perfectly appointed trip to Schenectady.

---

The one noticeable weak point of the convention was the conspicuous absence of committee reports. The officers of the association would do well to try and remedy this defect in future. The matter presented in papers can often be given or found in other ways, notably in the technical periodicals, and for it engineers are not dependent upon the association. Committee reports, however, have a value and strength, if thought and care is given to them, which cannot be obtained in other ways. One of the vital reasons for an association of electric light men is the work of the committees, and its failure is sure to greatly weaken the association.

---

While the papers read at the convention year after year reflect the progress of central station engineering, nothing indicates better the solution of old problems and the rising of new than does the discussion. Perhaps no class of engineers have more perplexing engineering troubles of their own than those in charge of central station work, and immediately following almost every paper of the last convention the discussion settled down in earnest upon some point that is troubling the managers of central stations this year. Most of the old problems, such as multiple rate metering, belted vs. direct connected sets, simple vs. compound engines, etc., evidenced their passing by their absence, the only prominent one remaining being the good old topic of direct vs. alternating current, which this year has new aspects brought in by the development of the rotary converter and double current generator, as well as by the increasing consolidation of rival companies operating direct and alternating current systems.

---

Following Mr. H. A. Wagner's paper the discussion on this point was precipitated by the propounding of the problem: Which is to be the ultimate system, and shall a central station manager giving both kinds of current make his extensions from his direct or alternating current lines? The general opinion seemed to prevail that if the alternating current motor and especially the single phase motor could be developed to give good service on direct geared elevators, the problem would be easily answered. It was pointed out that one of the greatest difficulties heretofore in alternating current motor work, the disturbance of voltage regulation, is not so much due to the fault of the motor itself as due to the fact that alternating current machines have, as a rule, been small with poor regulation and the lines have been built of any size wire that came handy, while direct current systems have been run with larger machines worked in parallel, supplying their loads over copper carefully proportioned for the proper drop.

---

Following Mr. W. S. Barstow's paper the discussion revealed another alternative now perplexing to engineers, viz., the use of steam or electrical auxiliaries. The net result of what was said upon this subject indicated the opinion that for condensing plants without economizers the steam auxiliary is the proper thing, as all its losses can be returned through the feed water; while for non-condensing plants or plants with economizers, there is an opportunity for a considerable saving of fuel by the use of electrical auxiliaries.

---

Following Prof. W. L. Robb's paper the discussion evidenced the desire of central station men to feed their arc lights directly or indirectly from the same machines that generate power for their other loads, and thus to do away with the belting and countershafting of series arc machines and possibly with the machines themselves. The series alternating arc is exciting at present the greatest interest, as it apparently offers the cheapest and simplest method of accomplishing this result. Its use, however, has as yet been so limited that central station men hestitate its adoption, awaiting to see what the result of time will be on the few installations now in service.

---

On the subject of the ageing of transformers, the papers of Prof. Goldsborough and Mr. G. W. Hubley showed two very felicitous conclusions. The first showed that in transformers as now made the ageing is practically negligible, and the second described a means of remedying that of the older types.

---

### The Proper Size of Transformers for Secondary Mains and Network.

Now that large transformers, with secondary mains for feeding the premises of several or many independent users of central station energy, have come to be accepted practice in place of independent house to house transformers, it requires considerable judgment to determine the best size of transformer to use for any such load. It is difficult to estimate how many of the lights wired to one transformer are likely to be in use at one time,

Digitized by Google

or what is more to the point, how many are likely to remain in service for a sufficient length of time, especially during warm weather, to injure the transformer through overheating. If safety is the only consideration and a generous size is chosen the efficiency on average loads is considerably reduced, and if on the other hand a transformer too small is put in service, it or its fuses may be burnt out or at least the ageing of the iron will be hastened through dangerously hot running.

---

A handy means of solving this problem is available in the maximum demand meters, especially those of the thermal type, such as the Wright meter, now on the market for another purpose. By placing one of these in the transformer primary and leaving it there during a representative interval of time a record will be obtained of the maximum amperes taken during that time, whereby the fitness of the size of the transformer in service may be determined. This simple kink in central station engineering is of particular value when the ability of a transformer to carry its load comes into question owing to the growth of business.

---

A similar use of the same instrument which is of even more value, is the determination of the proper grouping of transformers located at different points and interconnected by a secondary network either on the two or three wire system, which practice is rapidly growing in favor in districts of congested loads. It is a phyiscal impossibility to determine without some measurement of this kind whether a 10 kw. transformer at a street intersection is properly dividing the load with a 100-light transformer at the next corner. By the use of maximum demand meters in the primaries of the two transformers the division of the maximum can readily be determined and corrections made if the division overloads one and underloads the other, either by relocating one or the other of the transformers at different points on the secondary mains or by rearranging the copper of these mains

---

**Constant Current Transformers.**

The alternating current arc lamp has never been very popular in comparison with its direct current prototype, partly on account of difficulties with the governing mechanism of the lamp, which have now been overcome; partly on account of the noisy hum that early alternating current lamps emitted, which also has been remedied; and partly on account of the 25 to 40 per cent. lower output of light per unit input of energy and the poorer distribution of the light given out, which appear to be inherent objections to the alternating current arc as compared with the direct current. In spite of these difficulties the desire to operate arc lamps on alternating current circuits has stimulated the perfection, during the last two years, of many different makes of constant potential enclosed lamps for alternating current circuits.

---

One system of series alternating arcs on independent constant current machines has been developed but never put into very wide use, and in one large station in this country, that of the Missouri Edison Company in St. Louis, alternating arcs are run in multiple series banks across the high tension bus bars of large constant potential machines. The advantages of consolidating the various loads of a station upon one class of generators have naturally led to a general desire for some means of regulating alternating current series arc circuits run from constant potential mains, which means can be obtained by what are called constant current transformers, the term meaning that when supplied with constant potential on the primary sides they give constant current to their secondaries.

---

There are two fundamentally different means of obtaining this result. One would be by means of cutting in or out the turns of either the primary or secondary, which would involve mechanical apparatus of considerable complexity and troublesome contacts. The other is the use of transformers of considerable self-induction and movable coils, designed to be operated by the repulsion effect, and transformers of this kind have lately been perfected, standardized and put on the market for this purpose. Descriptions of transformers of this type and their performance in Hartford, Conn., will be found on other pages of this issue.

---

Naturally the power factor of such a transformer is low, in fact the transformer is specially designed for what would be considered bad regulation for constant potential work. There is no interleaving of primary and secondary and magnetic leakage is absolutely depended upon for regulation. Tests made in Hartford have shown a power factor at maximum load of 80 per cent. which, of course, falls off rapidly on lower loads. Tests have also been made of the efficiency, showing a maximum value of 96 per cent., a figure closely comparable with that obtained on constant potential transformers of the same capacity, viz., about 40 kilowatts. This efficiency, however, naturally falls off somewhat more rapidly on these transformers than on constant potential transformers, as the load goes down, owing to the great length of the magnetic circuit and the consequently high iron losses. The copper losses of the secondary are also the same no matter what the load may be.

---

No central station engineer should make an attempt to use such transformers on small machines, at least unless the machines are exclusively devoted to that load. On account of the large amount of lagging current their magnetic leakage introduces, such transformers would be likely to pull down severely the voltage of a machine which they alone would load. For instance, a 100 light transformer of this kind, having a capacity of about 40 kilowatts, would badly disturb an old type unitooth composite wound alternator of 100 kilowatts. Where, however, the machines are large, of several hundred kilowatts capacity each, of close regulation and running in batteries in parallel with each other, transformers of this type may be safely put upon them to the extent of at least 20 or 30 per cent. of their rated output.

---

**Electrical Installations in the West Indies.**

There will be found on the first few pages of this paper a description of an electrical transmission and railway plant in Kingston, Jamaica. The peculiar climatic conditions and the high prices of some structural materials involve features in this plant which are quite different from installations for the same purpose in this country. Among other things the poles of the transmission line are of steel and the power house itself is built entirely of steel and concrete.

---

There may be expected during the next few years an inrush of electrical plants to the new dependencies of the United States in the West Indies. Indeed, energetic prospectors have already determined the most valuable locations and rights and only wait the settlement of governmental conditions, upon which depend their franchises, before they take further steps. The engineers of such proposed improvements would do well to examine the most recent and improved West Indian electrical plants, at the head of which is that of the West India Electric Company, of Jamaica.

## THE APPARATUS FOR WIRELESS TELEGRAPHY.

BY PROF. JEROME J. GREEN.

The apparatus for demonstrating the effectiveness of telegraphing by means of Hertz waves is comparatively simple. In the experiments recently conducted at the University of Notre Dame all the essential parts of the sending and receiving stations were found in the regular equipment of the electrical and physical laboratories, except a few details which were constructed in the workshops by the students.

It has been known for several years that electric waves are propagated from an insulated conductor when this conductor is rapidly charged and discharged in such a way as to produce a series of very sudden disturbances in the surrounding ether. The waves are said to travel with about the velocity of light, but their length is much greater than the length of light waves, and this length depends on the character of the spark produced at the discharging terminals. These terminals, as used in wireless telegraphy, are always spherical in shape, with great variations as to size.

These electric waves of various lengths may be refracted or reflected like the waves of heat and light. They pass through many substances but are absorbed or reflected by metals.

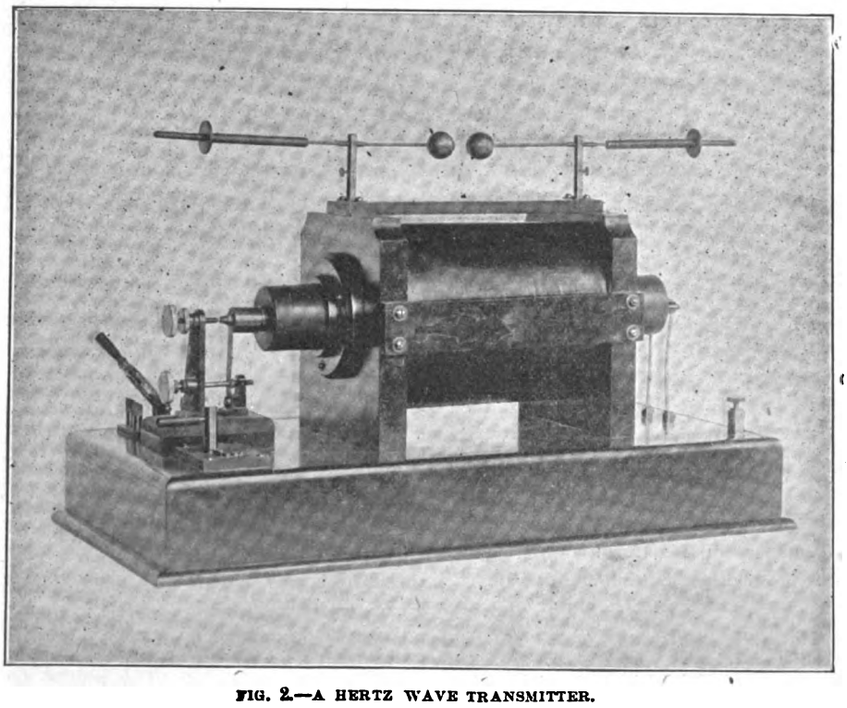

FIG. 2.—A HERTZ WAVE TRANSMITTER.

The parts required for a complete sending station are an induction coil capable of producing a stream of sparks from one to ten or more inches in length. A smaller coil will of course answer if the receiving station is located close to the sending apparatus—a suitable primary or secondary battery to operate the coil and a discharger or oscillator. The oscillator may be two large metal spheres placed about half an inch apart on insulating supports. The space between them is sometimes filled with a heavy petroleum oil, but this is not essential. Additional spheres or plates may be connected with each of the large spheres between which

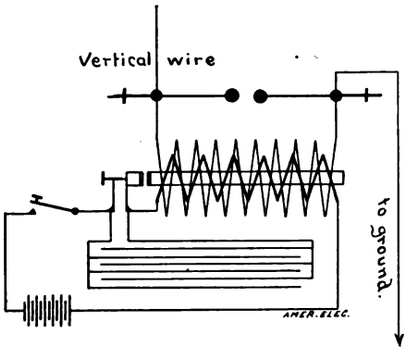

FIG. 1.—CIRCUITS OF TRANSMITTER.

the discharge takes place. These additions increase the capacity of the oscillator and change the character of the spark produced.

A simpler and more easily constructed oscillator is the vertical wire with a metal sphere at its upper end, in connection with two small spheres about an inch in diameter. This is the apparatus Mr. Marconi used. The lower end of the vertical wire is attached to one of the spheres and the other is fastened to a steam or water pipe.

An easy way to make this form of oscillator is to drill holes in two small metal spheres and put these spheres on the adjustable points, with which all induction coils are supplied, at the terminals of the secondary windings.

The vertical wire should be attached to one of the terminals of the secondary coil, and the ground wire to the other. (See Fig. 1). Then adjust the distance between the spheres, and the tension on the vibrating interrupter spring until a stream of thick, white, noisy sparks is produced when the primary switch is closed.

For the receiving station there is needed a coherer with a decohering tapper, a sensitive relay, and a sounder or a Morse recorder.

The coherer is, of course, the essential part of the receiving station. It may be made from a small glass tube, of, say, one-eighth of an inch internal diameter, and it may be about an inch and a half or two inches long. Into the ends should be fitted brass rods, and these plugs of metal should have a space between their ends near the middle of the tube, which space can be increased or decreased in length by sliding out and in one of the metal plugs. To complete the coherer a small quantity of filings of metal, such as silver or nickel, or a mixture of these metals, is put in the space between the plugs in the glass tube. Filings from the ordinary five-cent piece will answer very well.

This contrivance has the property of changing its resistance when it is acted on by the waves. A space in such a tube one-fourth of an inch in length, loosely filled with filings in their normal condition, will have a resistance of several megohms, but when the waves from the sending station strike the vertical wire attached to one of the terminals of the coherer the resistance of the coherer falls to about ten ohms. The coherer is put in circuit with a high-resistance relay, and a dry battery of one or two cells. When no waves are passing, the coherer has so high a resistance as to virtually open this circuit; but when the action of the waves begins, the decrease of the resistance closes the circuit, and the armature of the relay is drawn down and closes the circuit on a sounder, or on whatever we wish to add to the receiving set. The resistance of the coherer remains at this low value even after the waves have ceased to strike the vertical wire, but it becomes very high again when the filings are shaken. A little tapper like that on an ordinary electric bell is made to strike the side of the tube for this purpose. The relay in circuit with the coherer may close a circuit to operate such a decohering tapper or the filings may be shaken by tapping the tube with a lead pencil or by other mechanical means.

From the diagram, Fig. 3, it will be seen that the minute oscillating current produced in the vertical wire set up by the passing of the waves has the choice of two paths to earth; through the coherer, C, or through the relay, R. To prevent its passing to the relay and leaking across through the metal, well insulated choking coils A & A are placed in the circuit with the relay. The rubber-covered spools of a four-ohm telegraph sounder will do for these coils. The small current is then forced to go through the filings to ground, and this causes them to cohere as long as it is passing, even

Digitized by Google

though they are shaken. It is well to put some non-inductive resistance (such as the lamp shown in the diagram) across the points of the vibrating tapper and the tongue of the relay to prevent a spark there. It is especially important that the spark be prevented at the tapper, as it is so close to the filings that if considerable sparking occurred here it would set up waves which would cause the filings to cohere to some extent and prevent the decohering action of the tapper. The great difficulty in the first experiments at Notre Dame was to make the filings decohere quickly. If this action is not prompt it is impossible to make dots and dashes so that they can be distinguished.

Fig. 4 shows the coherer tube mounted on hard rubber supports on the top of the metal cover of an ordinary buzzer. An extension from the armature of the buzzer reaches through the cover and strikes the tube.

We employed in all our experiments an eight-inch induction coil of American make, with a heavy Apps vibrating circuit breaker. The current for the primary was furnished by a battery of six five-ampere storage cells. The double-pole jack-knife switch on the base of the coil served to open and close the circuit at first, but later a heavy telegraph key with special contacts was used. The coil is shown in Fig. 2.

An ordinary one hundred and fifty-ohm telegraph relay was employed in the receiving set for distances up to one-half of a mile, then a similar one of fifteen hundred ohms' resistance, with a lighter armature, was substituted for the ordinary relay, and it gave good results at distances of about two miles. Later a more sensitive relay was made by adding platinum contact points to the needle of a portable galvanometer of the D'Arsonval type. This responded more readily than either telegraph relay. Five small dry cells were used to operate relay, tapper and sounder.

We first suspended an ordinary No. 14 rubber-covered wire about ten feet long

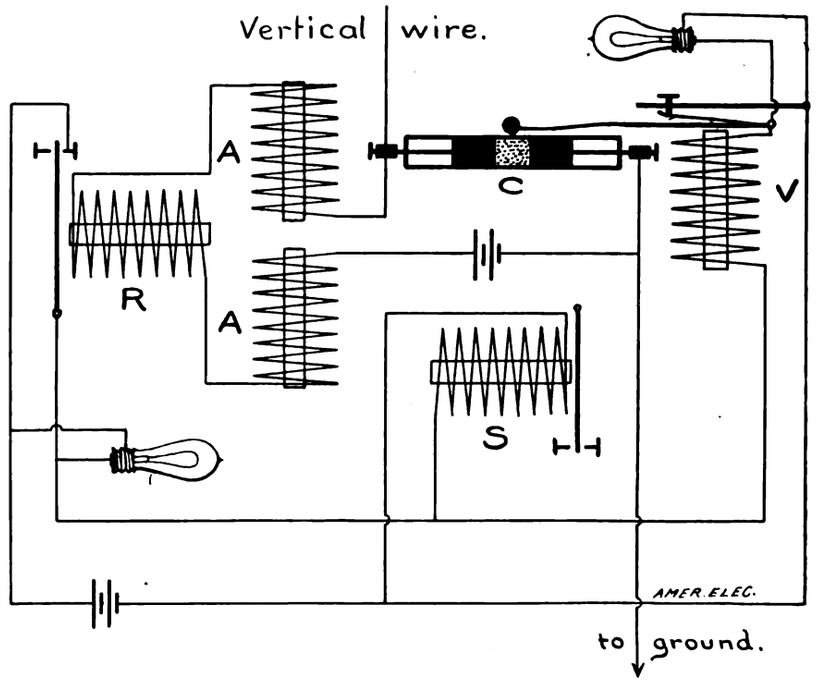

FIG. 3.—CIRCUITS OF RECEIVING APPARATUS.

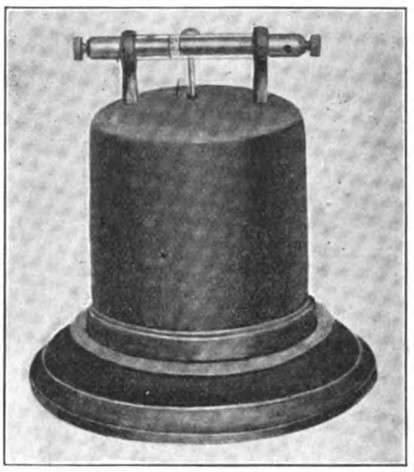

FIG. 4.—COHERER AND TAPPER.

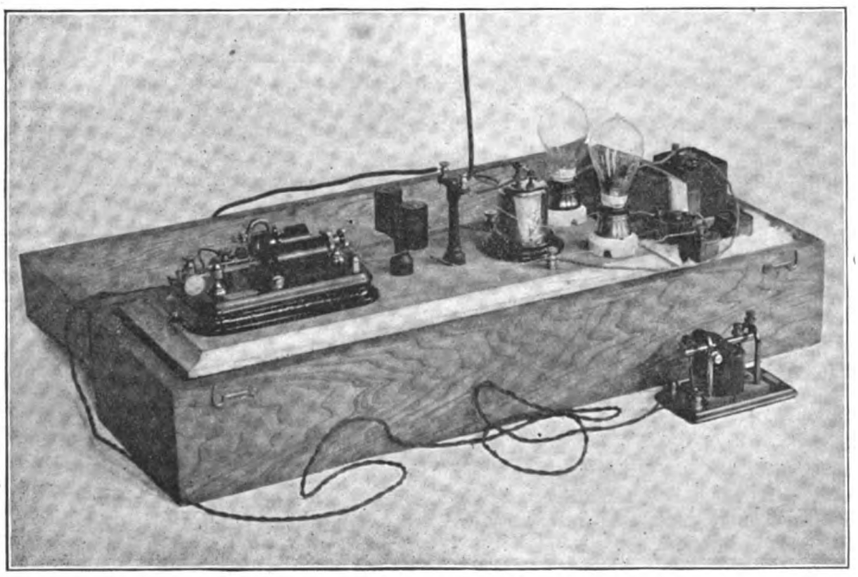

FIG. 5.—RECEIVING APPARATUS COMPLETE.

from the ceiling of the physical laboratory and attached its lower end to one of the binding posts at one of the terminals of the secondary of the induction coil; the other terminal was connected to a steam pipe near by. These binding posts also carried the adjustable pointed rods, on the ends of which were placed the polished brass spheres one inch in diameter. The tension of the vibrator springs was adjusted so that a spark about an inch long passed between the spheres when the circuit was closed. A similar wire about six feet long was suspended in an adjoining room with its lower end connected to one end of the coherer. A wire from the other end of the coherer was attached to a steam pipe. When the circuit was closed on the induction coil the filings in the tube appeared to be arranged in strings or chains as when they are strongly magnetized. Their resistance fell to about six ohms. A very vigorous shaking was required to cause them to resume their normal condition of high resistance. Cohesion took place in the tube of filings, but not so strongly, when the ground connection was removed from the coherer.

The receiving apparatus was then placed in a building about one hundred feet distant, and ground connections were made to a steam pipe. The same short vertical wire was used and the relay closed every time the coil was worked. The windows and doors of both buildings were closed. Next a wire about twenty-five feet long, with a metal sphere at its upper end, was suspended from the roof of Science Hall. The lower end was brought through a window and attached to the induction coil, and ground connection was made from the coil to a steam pipe. A similar wire and sphere were suspended from a window in the top floor of a three-story building across the campus, at a distance of about two hundred yards from the sending station at Science

Digitized by Google

Hall. The lower end of this wire was also brought through a window and attached to the coherer; the ground connection was made to a steam pipe. The impulses in this case were received as strongly as when we were working from one room to the next with the short wires. The receiving apparatus was next placed at a building about five hundred yards from Science Hall. The vertical wire was about twenty-five feet long and ground connection was made to a water pipe. The coherer responded readily at this increased distance. Its normal resistance, as measured with a Wheatstone bridge, was very high, more than a megohm. The tapper was then disconnected to prevent its shaking the filings, and when the circuit was closed on the induction coil at the sending station the resistance of the coherer instantly fell to ten ohms and remained at this low value until shaken.

The induction coil was next placed at the foot of a steel flag pole about one hundred and twenty-five feet high. The vertical wire and sphere were suspended from the top of the pole on a wooden bracket, which held the wire about ten feet from the pole. Ground connection was made to the base of the pole. The receiving apparatus responded at distances up to two miles when impulses were sent from the station at the flag pole.

In the last experiments at Notre Dame the vertical wire and sphere were suspended from a high church tower and the induction coil was placed about thirty feet up in the tower. The lower end of the vertical wire was brought through a window and attached to the coil. Ground connection was made to a water pipe. The active length of wire here was about one hundred and fifty feet. The impulses were received strongly at a distance of three miles, about one mile of this space being occupied by the city of South Bend. Another trial to Mishawaka, a distance of about six miles across the country, resulted in failure.

Trials were made in Chicago among the steel buildings and overhead wires in the business district. When the sending station was located at the Polk street railroad station and the receiving apparatus at the "Tribune" building, a distance of about three-fourths of a mile, the relay failed to respond when the coil was operated. In this case a line drawn from the sphere at the top of the wire at the sending station to the similar sphere at the top of the wire at the receiving station would be intercepted by many electric light, telephone and telegraph wires running in every direction. These wires apparently absorbed the waves, for in another trial from the Monadnock Block to the "Tribune" building, there was a clear space between the spheres at the tops of the wires. The receiving apparatus responded strongly. The distance in this second experiment was about half that at which the first trial was made.

Later the sending apparatus was set up at the life saving station at the mouth of the Chicago river, and the receiving set was placed on a tug. One wire and sphere were suspended from the end of a pike pole lashed to the railing on the lookout of the station, giving an active length of about forty feet. Ground connection was made by attaching a wire to an iron pipe placed in the water. The other wire and sphere were suspended from a short mast on the tug, giving an active length of about thirty feet. Ground connection was made by attaching a wire to a piece of iron hung out over the stern of the tug. The impulses caused the

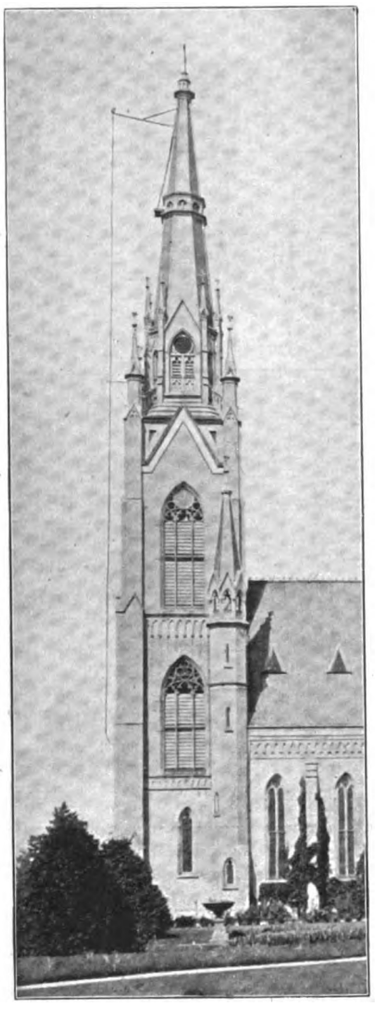

FIG. 6.—THE TRANSMITTING WIRE AT NOTRE DAME.

sounder to operate very strongly until a distance of about two miles out in the lake was reached, when the sounder ceased to respond.

It seems from these trials that it is much easier to operate over water than over land. This result is also indicated by the great distances Mr. Marconi has attained over water, while Ducretet, with the best instruments that skill can produce, has succeeded in sending messages only about five miles over the city of Paris, where there are no overhead wires to interfere. Our experiments with crude apparatus show that it is quite easy to reach short distances, but it is quite difficult to adjust all the parts to make the dots and dashes accurately.

## AMERICAN TELEPHONE PRACTICE.

### TESTING.*

BY KEMPSTER B. MILLER.

Tests of telephone lines, whether of bare wire on poles or of overhead or underground cables, may be divided into two general classes:

First: Those which are for the determination of the existence of certain conditions, without the necessity of measuring quantitatively the extent to which those conditions exist. In other words, rough tests for the determination of grounds, crosses or breaks, usually made with instruments such as the magneto-bell, telephone receiver and battery, and a few other such simple but often in the hands of an experienced person most effective instruments.

Second: Those for not only determining the existence of certain conditions, but also for their quantitative measurements. These require the use of different and more intricate instruments, and in many cases the operator must be possessed of a fair degree of mathematical training combined with an ingenuity for meeting and mastering unusual problems that arise under different conditions.

The magneto testing set is the most important instrument in making tests under the first class. Such an instrument usually consists of a powerful magneto-generator so wound as to enable it to ring its own bell through a resistance of from 25,000 to 75,000 ohms. A powerful magneto-telephone is carried on the outside of the case in suitable clips, and may be switched in circuit alternately with the generator by a small hand switch. This magneto-telephone serves as both transmitter and receiver, and enables the lineman or other party to communicate from a pole top or man-hole with any other party on the circuit. Frequently these sets are made to include microphone transmitter and battery; but, inasmuch as the instrument is seldom if ever used to talk over very long circuits, the extra weight of these is considered in most cases undesirable. A small, inexpensive galvanoscope or current detector will also prove very convenient.

In testing for a ground on a wire, whether it be in a cable or bare and on poles, make sure that the far end of the line is open and then connect one terminal of the magneto-bell to the near end of the line and ground the other terminal. The ringing of the bell would seem to indicate that the circuit was complete and the line grounded in this case, but this is not always true, and this test must therefore be relied on only with caution. The static capacity of a long line or of a comparatively short length of cable will often allow enough current to pass to and from the line in charging and discharging to ring the magneto-bell.

For testing out local work where there is no room for this capacity effect, the magneto-bell is invaluable.

* From a book to be published by the American Electrician Company.

Digitized by Google

A more reliable means of making tests for grounds or crosses is to connect the current detector in series with several cells of battery and to ground one terminal. Then with the other terminal make contact with the near end of the line. A kick of the needle will take place in any event on closing the circuit, due to the current flowing to charge the line, but a permanent deflection will indicate a ground.

In testing for a cross, as for instance with some other wire in the line or cable, one terminal of the magneto-bell or the galvanoscope and batteries should be connected to the wire under test and the other to all the other wires in the same

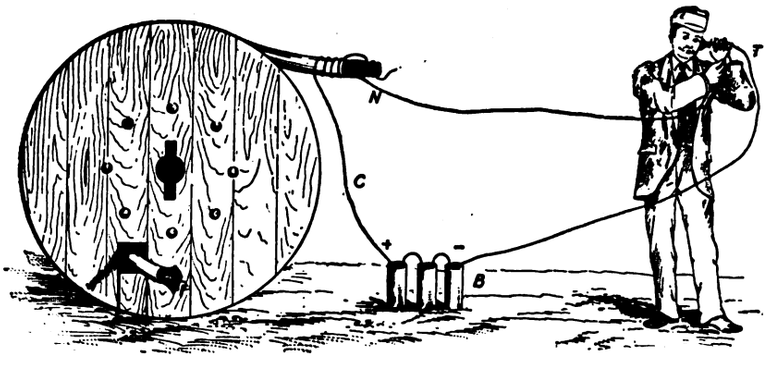

FIG. 1.—RECEIVER TEST FOR CROSSES AND GROUNDS.

lead for which purpose they are bunched. In case it is not convenient to bunch them, however, the test may be made between the suspected line and each of the others in succession.

Another and perhaps still more simple method for determining a cross or ground is one described in Roebling's pamphlet on Telephone Cables, and illustrated in Fig. 1, as applied to the testing of a cable before it has been unreeled.

N represents the near end and F the far end of the wire being tested. B is a battery of about three cells. T is an ordinary telephone receiver. The wire, N F, is carefully separated from all the others at each end.

At the near end all the wires are stripped of insulation and except the one under test are connected together and also with the sheath. The wire, C, connects the sheath to one side of battery, B, and the other side of battery is connected to one side of telephone receiver, T. The testing man rapidly taps with the wire, N F, the unoccupied binding post of the receiver, T. The first tap will produce in the receiver a distant click, and if the cable is long there may possibly occur a second faint click, but if the wire, N F, is perfectly insulated, no more sound in the telephone will follow the tapping. If, however, the wire, N F, is crossed with any wire in the cable, or with the sheath, every tap will be followed by a distinct click, and if there is moisture in the paper, making a partial connection, clicking sounds will occur, which are loud or faint, according to the amount of moisture present.

The philosophy of this method of testing is very simple, and serves to make the operation more readily understood.

When the wire, N F, is first connected to battery, it becomes charged. During the time it is filling with electricity a current flows. This current passes through the coil of the receiver and causes the click. If the wire is well insulated, the second tap, immediately following, finds it charged, or nearly so, and there is, therefore, no click, or a very faint one. If, on the contrary, the wire under test is crossed with any of the other wires, or imperfectly insulated from them, or from the sheath, the wire will immediately discharge itself through the cross to ground and there will be a flow of current at every tap, and consequently a continuous clicking. If a conductor in a perfectly insulated cable is very long, two or three taps or a long first contact may be necessary to charge it completely.

If the cable is in place or if it is a bare aerial line that is being tested this same method may be used. In case of a new cable it is well to test every wire in this manner, and therefore the wire, N F, should be put aside and another slipped out of the bunch and tested in the same way, and so on until all have been gone over. If any of them are found to be in trouble, it is well to carefully inspect the exposed ends to be sure they are properly cleared from each other and from the sheath. If it is still found to be defective, it should be plainly tagged.

In the manner just described, twenty-five minutes with two men should be ample time for testing one hundred wires, the testing operator listening and his helper attending to the connection of the different wires at N.

For this test as well as many others it is very convenient to use a regular operator's receiver and head band, as it will save the tester a very tired arm at the end of a long test.

The continuity test, or test for broken wires, may be made with the same simple instruments. The wires to be tested should all be grounded at the far end. At the near end, one pole of a magneto-bell, or of the battery and galvanoscope, or of the receiver, should be connected to ground and the other terminal connected successively to the terminals of the line, which, of course, should all be separated. A ring in case of the magneto, or a deflection of the needle in the case of the galvanoscope, or a continuous clicking in the receiver, will indicate that the wire is continuous. The same precaution as previously pointed out must, however, be observed with the magneto-bell. This same test for continuity is well illustrated in Fig. 2, in which case a vibrating bell instead of the receiver or galvanoscope is used.

In testing a cable all defective wires should be marked, "crossed," "grounded" or "broken" at the end at which they are tested. The corresponding ends of the tagged wires at the other end of the cable should then be found and similarly marked.

If there are not the requisite number of good wires in a new cable is should be rejected.

It is often desirable to be able to pick out a certain wire at some intermediate point in an open cable, or in a large bunch of insulated wires, in order to establish a branch connection. This is easily done by the foregoing methods if the cable is to be cut, but frequently this is not the case. It may be done without cutting by the following simple method: Ground the wire or wires desired at the distant end, being sure that these wires are free from all the others at both ends.

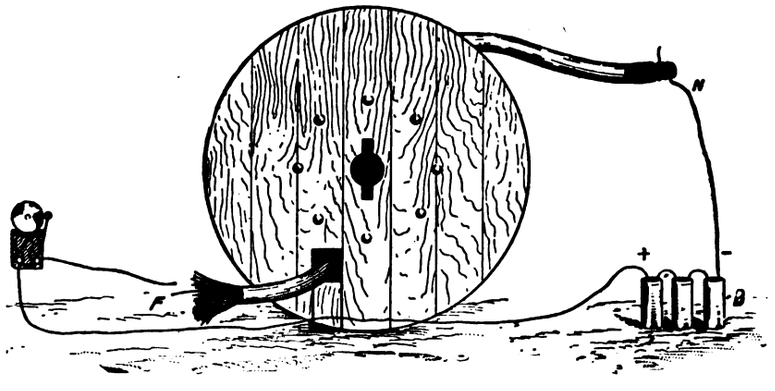

FIG. 2.—CONTINUITY TEST.

Then having loosened the bunch of wires at the point at which the branch is to be taken off, test each by means of a needle-pointed instrument, connected to ground through a bell or receiver and battery. The needle-point can readily pierce the insulation and make good contact with the conductor within. A knowledge of this very simple test will often save an immense amount of trouble.

## STEAM AND WATER REDUCING VALVES.

Boiler-room economy calls for the generation of steam at high pressures, but many appliances necessitate the use of the vapor at a pressure much lower than that at which it can be profitably generated and used in engines. Undoubtedly, the first attempts in this direction were to throttle the steam by means of a valve

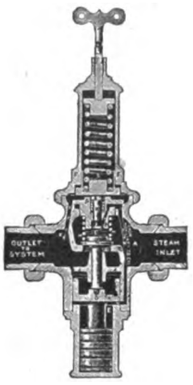

FIG. 1.—MASON VALVE.

in the supply pipe, adjustments being made thereto when necessary, as determined by reference to a pressure gage connected with the low-pressure side of the throttling valve.

Such a crude piece of apparatus would soon be improved by making the low-pressure steam open or close the supply valve, according as the consumption increased or diminished. Some sort of a piston and cylinder, or diaphragm arrangement would naturally suggest itself for this purpose, and such devices are used for that purpose in a great multiplicity of form and arrangement, as shown by the following illustrations and text.

One of the well known forms of reducing valve is shown in Fig. 1, which is of

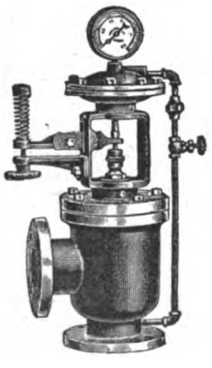

FIG. 2.—FISHER VALVE.

the piston type, and is known as the Mason valve, being made by the Mason Regulator Company of Boston, Mass. In this valve steam enters from steam inlet through an auxiliary valve which is normally held open by a spring. A differential piston is then raised by the pressure of the steam, and in turn opens the main valve and admits steam until the phosphor bronze diaphragm is raised at the point determined by the tension upon a key adjusted spring. Then the auxiliary valve is closed, thereby seating the main valve by means of the initial pressure. This action is repeated when the low pressure drops below the stated point.

Fig. 2 shows a type of diaphragm reducing valve in which the variable adjustment is also by setting a spring, although another form of this valve is made with a weight substituted for the spring. The weight style is particularly adapted for very low pressures, and it is claimed that the pressure will not "sneak up" as boiler pressure increases, when this valve is used. By connecting the diaphragm supply pipe with a pressure tank this reducing valve is readily made to answer as a pump governor. This valve is made by the Fisher Governor Company, Marshalltown, Iowa.

Valve makers find it necessary to employ special methods to prevent sticking and friction. One way of doing this is to dispense with all stuffing boxes, thereby enclosing both spring and diaphragm in

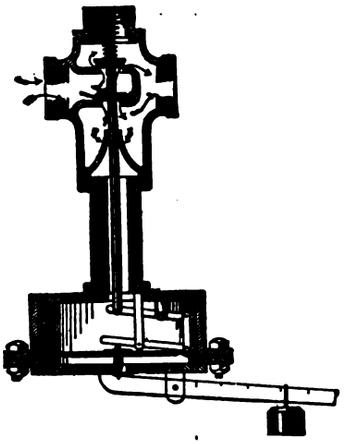

FIG. 3.—A SENSITIVE VALVE.

the same chamber on the low-pressure side of the valve. Fig. 3 shows this as executed by the Kitts Manufacturing Company, Oswego, N. Y. The valve is fully balanced and a spring is used to seat the discs against the boiler pressure. The diaphragm is so connected with the valve stem, by means of compound levers, that pressure against the diaphragm also tends to close the balanced valve. At the same time the compound lever gives a long movement of the valve with a very short movement of the diaphragm.

A valve is shown by Fig. 4, which dispenses with all springs, diaphragms and packing. It is known as the Davis Pressure Regulator, and is manufactured by G. M. Davis, Chicago. It is also catalogued by the Crane Company of the same city. The valve stem carries a piston arrangement in the cylinder, shown in the bonnet, and a yoke device connects the piston with a double-ended lever to which two weights are attached, thereby allowing the necessary pressure adjustments to be made at will. A dash-pot is shown, and is used only when there is a vibration or pulsation of steam. This device is omitted when there is no pulsation of pressure.

In some spring controlled reducing valves, tension on the diaphragm is not uniform. A compensating device is shown in Fig. 5, whereby the diaphragm is made independent of the amount of spring compression. This is done by the toggles shown in the engraving, whereby the increasing power of the spring is com-

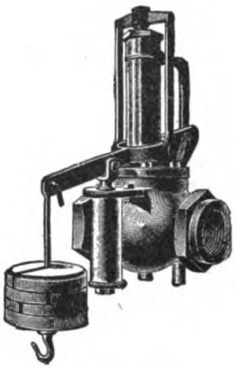

FIG. 4.—THE DAVIS PRESSURE REGULATOR.

pensated by the increasing power of the toggles as their angle is reduced. A system of levers is also employed to enable a small diaphragm to control a large valve.

This valve, which is made by the Foster Engineering Company, Newark, N. J., has a device which allows both discs of a double-seated valve to remain tight under varying temperatures. This is done by making the angle of the upper disc and seat obtuse, and of the lower acute, but still of such angle that it cannot "stick." The lower disc finds its bearing by diametrical expansion, due to the temperature of the fluid.

All diaphragms, springs and packings are dispensed with and there is little possibility of sticking in the valve shown by

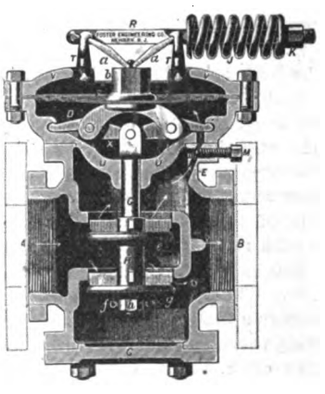

FIG. 5.—FOSTER PRESSURE REGULATOR.

Fig. 6. It is noiseless in action, and there is no dash-pot or oil cylinder. In fact, as illustrated, the Monarch Pressure Regulator, made by the Van Auken Steam Specialty Company, Chicago, Ill., is a simple positive form of reducing valve with several valuable features.

A piston, acting against a weighted lever, furnishes the working power, and

Digitized by Google

the lever is connected to the valve stem by means of a long sleeve which fits outside an elongated bonnet, thereby avoiding a stuffing-box. The lever may be fastened to any part of the sleeve, thereby allowing the lever to be adjusted at an angle therewith, so as to avoid steam pipes, beams or other interferences. The lever is also swivelled so that it can be turned at any angle. A screw-stem and hand-wheel at the bottom allow the valve to be closed tight at will.

Types of both high and low-pressure reducing valves are shown by Fig. 7. These valves are made by Kieley & Mueller, New York City. The high-pressure valve is operated by low-pressure steam acting against a piston, the opposite side of which is open to the atmosphere. Steadiness is imparted by a piston upon the lower end of the valve-stem, said piston working in a cylinder filled with water of condensation. The "atmospheric piston" is made tight by Garlock's or Crandell's packing, and is claimed to be almost frictionless.

In the low-pressure valve there is a diaphragm instead of a piston, the stuffing-box being dispensed with. The method

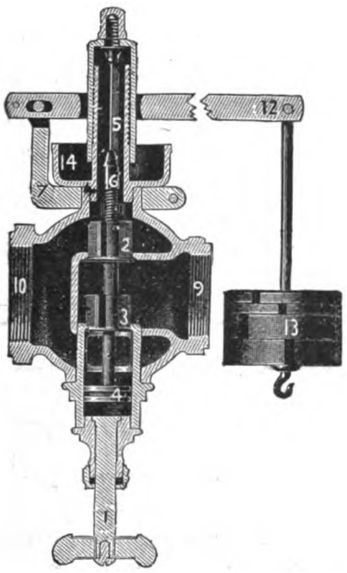

FIG. 6.—MONARCH PRESSURE REGULATOR.

of construction is so clearly shown by the engraving that no further description is necessary, except to state that the terms "high" and "low" pressure mean, in connection with these valves, above 15 pounds, and below that pressure, respectively.

Another valve, designed for reducing steam to an extremely low pressure, for use in vacuum systems of heating, is illustrated by Fig. 8, and made by the Standard Steam Specialty Company, New York, and is known as the "Utility Reducing Pressure Reducing Valve," although the purpose of such a title does not appear upon an inspection of the valve.

The construction is about the same as that already described for diaphragm valves, the diaphragm being very large in proportion to the steam inlet. A double-weighted lever furnishes means of adjustment. One peculiarity of this valve is that it is flanged and comes bolted to a pair of companion flanges, a fact greatly

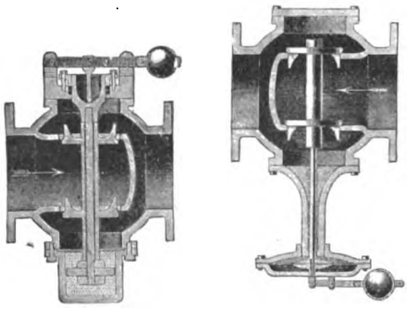

FIG. 7.—HIGH AND LOW PRESSURE KIELEY VALVES.

appreciated by the workmen who have to put up or keep in repair steam fittings of this class.

A double cylinder, double piston pres-

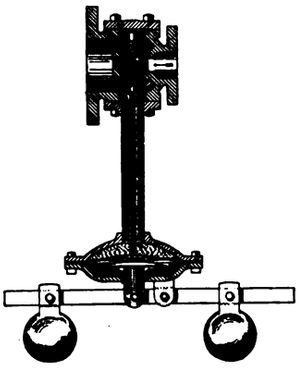

FIG. 8.—UTILITY REDUCING PRESSURE REDUCING VALVE.

sure regulator, made by the Newark (Ohio) Regulator Company, is the subject of illustration in Fig. 9. This valve and those next described are designed for

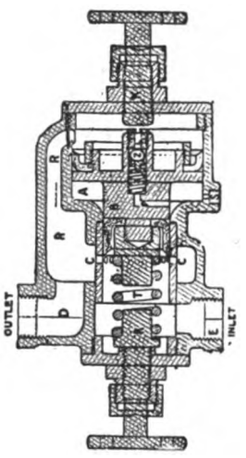

FIG 9.—NEWARK PRESSURE REGULATOR.

reducing water pressure rather than for steam, although they may be used for that purpose if desired. The fluid under pressure acts upon the small end of the piston, escapes through the port and acts upon the large piston, which, when a certain pressure is reached, is forced back, covering the ports and reducing the pressure on the outlet side of the regulator.

The small relief valve shown at the right of the engraving may be set at any desired pressure, and any excess over the stated amount forces the valve open, allowing enough fluid to escape that the pressure may be relieved. As none of the valves come against seats, all jarring noises from that cause are impossible, and the entire working of the valve is very easy and noiseless.

The Mason Water Reducing Valve, as depicted by Fig. 10, is a double-spring appliance with screw adjustment, and is controlled by a diaphragm. This valve is designed for use between a high pressure street service and low pressure for houses. Inactive water enters from the right, passes through the valve, which is held open normally, by action of the lower spring. Water also enters the diaphragm chamber through the communicating passage shown, and when the desired pressure has been accumulated the diaphragm is forced down and seats the valve. When the pressure lowers in the system the springs again force the valve open and the action noted is again repeated.

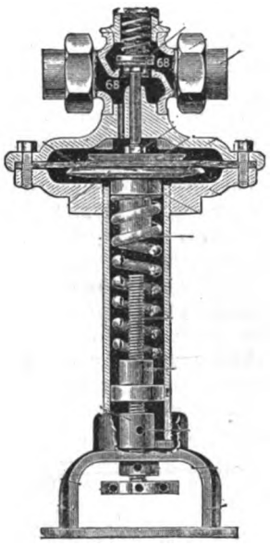

FIG 10.—MASON WATER REDUCING VALVE.

About the only difference between a pressure regulator and a pump regulator, is in the fact that the diaphrgm or controlling piston is connected to the water delivery in the latter named appliance, and to the low-pressure steam pipe in case of the former. Many pump regulators make excellent reducing valves; in fact, all can be thus used if desired, and some water regulators can likewise be thus used.

Quite a number of the steam and water pressure regulators above described can be used to advantage as pump regulators, but not all, and that comprises the difference between the two appliances, viz.: All pump governors may be used as pressure reducers, but all reducing valves cannot be utilized as pump governors.

One of the interchangeable type is il

Digitized by Google

lustrated by Fig. 11, and is made by the Watts Regulator Company, Lawrence, Mass. This appliance consists of a double seated valve with a long vertical stem which passes through a partition separating high from low-pressure steam—or water. There is a small pipe which connects the water well with the point where the reduced pressure is required. It is the partition and connecting pipe which enables this valve to do double duty, as noted

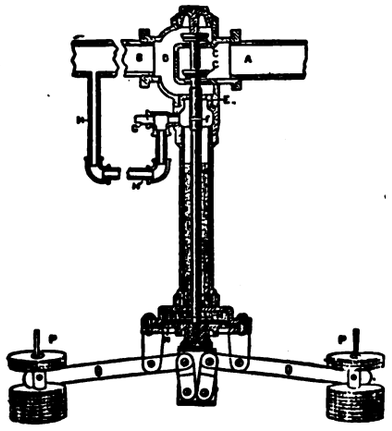

FIG. 11.—WATTS PRESSURE REGULATOR.

above. The ratio of pressure reduction is regulated by the double levers and variable weights shown at the bottom of the engraving. This form is recommended where the reduced pressure exceeds 20 pounds. For less than that pressure a single lever regulator is made.

Another pressure regulator which has a similar connecting pipe between diaphragm and low-pressure piping, is shown by Fig. 12. This regulator was originally patented by John Acton, 193 Worth Street, New York City. It has a balanced double valve which is connected to the diaphragm by means of a system of levers, in which there is an adjustment to make the valve open earlier or later, as desired. This adjustment may also be used to a limited extent for varying the

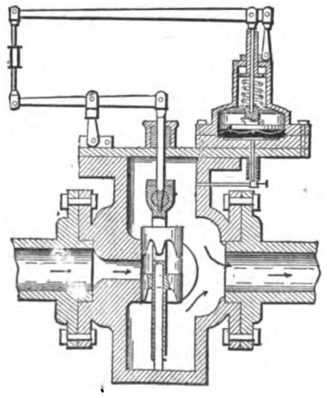

FIG. 12.—ACTON'S PRESSURE REGULATOR.

pressure of reduction, but the principal means of adjustment is in a hollow screw above the diaphragm. This appliance is quite small compared with the valve area, and is provided with a follower which travels with the diaphragm. The hollow screw mentioned above is placed upon the follower stem and is threaded to the diaphragm case, the stem playing easily through the hollow screw.

A double-seated valve with the top valve loose on the stem, is the subject illustrated by Fig. 13, which may be termed the M. & G. automatic Steam Pump Governor and Pressure Regulator. The upper valve being loose, yet close fitting upon the stem, compensates fully for expansion by means of a diaphragm in the upper valve which connects that with the stem.

The water piston is balanced by a weight and lever, as shown, and immediately above is a brass cylinder with a tight fitting piston, which is connected directly to the pump discharge which controls either by pressure in a closed tank, or by having the pipe opening placed at such a point in an open reservoir, in which case water flows into the cylinder pipe when the tank is full, and the weight of water in cylinder and tank causes the piston to descend and close the regulator valve. This valve is made by A. Metz & Co., Chicago, Ill.

A pump valve which takes little room and has no projecting levers or pendant weights, is shown by Fig. 14. This valve is principally designed for elevator, house and fire pumps, but will work anywhere that a water reducing valve is required.

A piston in the upper portion of the device is piped to the accumulator on pressure tank. The coiled spring holds the

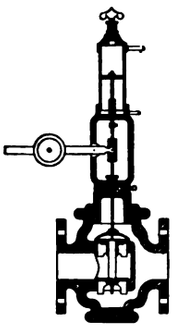

FIG. 13.—M. & G. PRESSURE REGULATOR.

valve open against the steam pressure and the nuts upon standards, shown at either side of the spring, force the latter to any desired adjustment. This valve is made by Thos. W. Ford, 130 Willoughby Ave., Brooklyn, N. Y.

An angle valve of similar action, but much different in construction, is illustrated in Fig. 15 herewith. A double-seated poppet-valve, held open by a spiral spring which is enclosed within a circular spring case, which, in turn, passes through a gland, on the outside of which is a projection which serves as a piston to restrain the valve against too sudden movements. The valve being unbalanced by pressure on an area equal to a cross-section of the valve case, the mode of operation at once becomes apparent and easily understood.

The diagram at the right represents the valve as above described, and the left-hand portion of the illustration shows an application of this valve which is of great service when concerns have their own fire pumps in connection with city pressure, or a high-pressure reservoir. The engraving shows this valve so arranged that a pump can force water directly into the fire mains, and not into the city pipes. It also excludes water from said city service unless the demand for water should be so great that the pump is unable to maintain the required pressure. In this

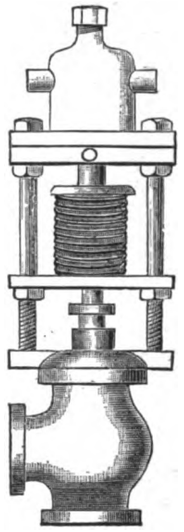

FIG. 14.—FORD REGULATOR VALVE.

case the reducing valve acts and allows city or reservoir water to flow as long as needed to make up the deficiency. The check valves shown are simply to prevent

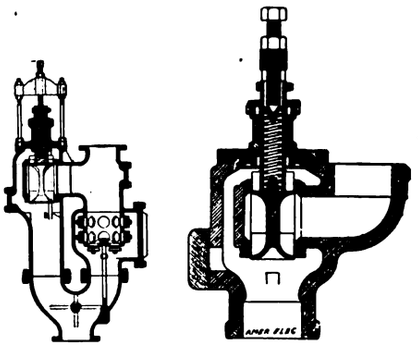

FIG. 15.—DORSMAN'S AUTOMATIC VALVE.

a flow of water in the wrong direction. This valve was invented by J. H. Douseman, 414 Matthews Building, Milwaukee, Wis.

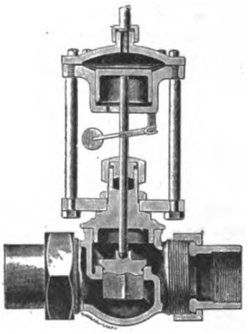

FIG. 16.—CROSBY WATER REDUCING VALVE.

A type of regulator-valve is shown by Fig. 16, whereby all the mechanism is attached directly to the bonnet of an ordinary valve. The closing mechanism is a

Digitized by Google

weight which acts against the pressure of water. The valve-closing device is a diaphragm working down upon a follower, closing the valve directly and positively. The only frictional contact is between the small valve stem and a stuffing-box. The valve disc is entirely separate from the valve stem, which has merely a

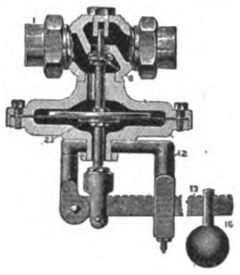

FIG. 17.—MASON VACUUM VALVE.

point bearing against it, permitting the device to act as a check valve as well as a pressure reducer.

Figs. 17 and 18 present two distinct types of "Vacuum Pressure" regulating valves. They are used chiefly for controlling steam where vacuum systems of heating are employed.

Fig. 17 is known as the Mason Vacuum Valve, and is used to maintain a vacuum of a certain number of inches of mercury. It may be kept on a certain pipe or system, while the pump is maintaining as great a vacuum as possible at all times. Little description is needed when once it is realized that this valve is to vacuum exactly what a reducing valve is to steam pressure.

The valve shown by Fig. 18 is especially used for a straight reduction of high-pressure steam to a point below the atmospheric line, a difference in area between the two valves, acting against pressure on a diaphragm. The ratio between

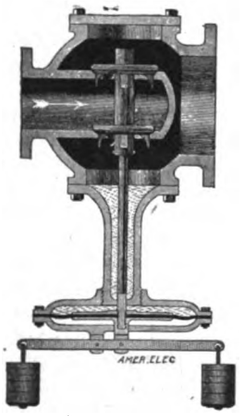

FIG. 18.—KIELEY'S VACUUM PRESSURE REGULATOR VALVE.

the two being controlled and adjusted by the double lever and weights, as shown.

These valves are also made with a graduated lever when desirable that very close regulation be secured.

A reducing valve which avoids entirely the use of all springs, levers or weights is shown by Fig. 19 herewith. The usual diaphragm is employed and the chamber in the lower part of the appliance, below the diaphragm is filled with air under pressure according to the reduced pressure of steam required. A seat is provided into which the diaphragm disc is forced when the valve is wide open, and when there is no pressure in the main pipe. This relieves the diaphragm of the strain otherwise put upon it. The air chamber is charged by means of an ordinary bicycle pump, or with a gage tube. The air pressure may be varied to obtain any required pressure in the steam main on the low pressure side of the valve.

As shown by the appliance above and below the double poppet valve, the muffler principle has been applied, making the action of the valve practically noiseless, even when passing a large volume of

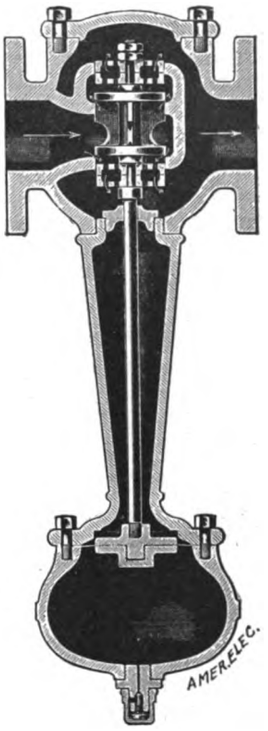

FIG. 19.—AIR-SPRING VALVE.

steam. It is the intention of the manufacturers, D'Este & Company, Boston Mass., to secure in this valve, among other things, a device whereby dry steam may be secured at all times, despite boiler fluctuations, by slightly reducing the pressure so that re-evaporation will take care of all moisture in the steam.

## THE OPERATION OF ALTERNATING CURRENT FAN MOTORS AT DIFFERENT FREQUENCIES.

BY P. M. HELDT.

It is often desirable to operate a fan motor designed for a frequency of 16,000 alternations per minute from a circuit of 7200 alternations per minute, or vice versa. In such cases the questions arise: Will the motor operate satisfactorily at the changed frequency without any changes in the winding or connections? If not, what changes have to be made to adapt the motor to the new frequency? What will be the relative current consumption at the two frequencies?

The alternating fan motors now on the market are based in their design on different principles, and these questions can only be answered by referring to a particular type. All alternating fan motors belong to either of the following types: Laminated field series motors, induction motors and synchronous motors.

The speed of the laminated field series motor is not, to any great extent, dependent upon the frequnecy at which it is operated, and motors of this type can, therefore, be run from both low and high frequency circuits. Of course, the hysteresis loss in the laminated field core is greater or less in proportion to the frequency, and for this reason a motor intended for 7200 alternations would be somewhat less efficient when run at 16,000 alternations. On the other hand, the counter e. m. f. of self induction would be greater, the higher frequency choking both the current more and reducing the power.

With the induction type of fan motors, which is that most used, the case is different. The speed of rotation is here directly proportional to the frequency, and inversely proportional to the number of poles. These motors are therefore not directly interchangeable on circuits of different frequencies; but if we can change the number of poles in the inverse ratio of the frequencies, the motor ought to still run at about its regular speed. An induction desk or bracket fan motor for 16,000 alternations usually has eight poles, and one for 7200 alternations four. Now it is plainly impossible to make an eight-pole machine out of a four-pole machine, but a four-pole motor can be made out of an eight-pole motor by connecting the field coils in such a manner that two neighboring poles are of the same polarity. A corresponding change would have to be made in the device which renders the motor self-starting. If, for instance, the motor has shading coils surrounding one-half of each pole, these have to be replaced by coils on every alternate pole surrounding the entire pole. There are now only four magnetic circuits in the field instead of eight, as before, and the magnetic density in the yoke will have to be doubled. The magnetic density in high frequency motors is usually quite low, and it would not be very difficult to double this density.

A motor thus reconstructed should give fairly good results, although it will be lower in efficiency than a motor specially constructed for this frequency, owing to the uneconomical distribution of the iron in the field core and the fact that a certain amount of electric energy when expended in one coil will produce considerably more magnetic effect than when expended in two smaller coils placed in parallel magnetically. When it is considered that the motor will be rather less efficient and that considerable work is required to make the necessary alterations it appears hardly worth the while to change a fan motor in this manner.

A synchronous fan motor will operate only on one frequency.

## A Puzzle.

*To the Editor of American Electrician:*

Sir—A few years ago I placed telephones connecting the house and a stable of a summer residence. For reasons then in force the Watson switch was not used. The ringer magnets were wired permanently in the main circuit, and shunted by differentially wound resistance coils, intended to have enough resistance to send a great part of the ringing current through the magnets, and to serve as a non-inductive path for speech currents, past the magnets. It worked well.

The place is occupied only during the summer. A few days ago, on reoccupying it for this season, the stable telephone was found to work unsatisfactorily. On inspection I found the resistance coil shunts burned at both stations. The house and stable are about one thousand feet apart. The "line" is lead encased wire under ground, with a No. 16 copper conductor, Okonite rubber, braided, and heavy lead covering. With the exception of a short distance near the center, the cable is four or more feet below the surface, and is nowhere exposed above the surface; at the ends it enters the cellars, low down through the foundation walls. The wires from the telephones are connected with the copper core and lead case respectively, the latter, of course, serving as a return. The system has no connection with any other wires. Where and how did lightning get on that line sufficient to burn the resistance coils, and, if differentially wound coils have no inductance, why did they burn in places instead of the whole coil being heated? The magnet wires were not burned. I enclose herewith one of the burned resistance coils for your inspection.

F.

*To the Editor of American Electrician.*

Sir—Supplementing my recent description of damage to telephonic apparatus, connected with an underground line.

A lightning storm passed over that place yesterday afternoon. A discharge struck a large stone-capped chimney on the house, breaking the cap and scattering the chimney for several feet from the top, when it apparently found sufficient conductivity to carry it down without further damage. No effect of the discharge could be found on any wire or elsewhere in the house, but the wires of the bell magnets in the stable were burned in many places, both on the surface and at the core. The stable building was not struck. The wires leading from the end of the cable in the cellar to the telephone are the only electrical wires in the building.

## The Effect of Capacity Upon Alternators.

*To the Editor of American Electrician.*

Sir—The three-phase transmission line of the San Joaquin Electric Company is operated at 19,500 volts and extends a distance of 70 miles from the power house to Hanford. Current is supplied to Hanford at the extremity and also at Fresno, midway betwen the two extremities. When the line switches are open at the power house the voltage on the generator bus bars drops several volts, and when they are in at the power house and nothing connected to the line at Fresno or Hanford, the voltage on the generator bus bars rises several volts. In other words, the voltage of the generator is higher with the open line connected than when running empty with nothing connected. Please explain the cause.

J. A. THUNEN.

North Fork, California.

The action described is due to what are called condenser currents coming out from the machine to charge the long overhead transmission line. The line is so long and the voltage so high that these currents amount to considerable and affect the machine, as described in the "American Electrician" of April, 1899, on page 179. The action of capacity on alternating current lines is peculiar. As the electromotive force of the machine rises a current flows through it to give an electro-static charge to the line whether there is any load connected or not. Thus, considering a single alternating wave of e, m. f. there is a current flowing to line as the e. m. f. rises and nothing when the e. m. f. is at its maximum point and not changing in value. Thus the current is ahead of or leading the e. m. f. and tends to have exactly the reverse effect of a lagging current, that is, at the instant when it flows in the armature conductors they are in such a position that this leading current tends to strengthen the field.

## The Machine Winding of Continuous Rings.

*To the Editor of American Electrician:*

Sir—Could you or any of your readers tell me of a machine, or how to construct one, that would wind wire on a continuous or closed iron ring core, such as a Gramme ring armature, or the regulating coils on the G. E. alternating fan motor? I should like to take the wire from a spool without winding it upon a shuttle.

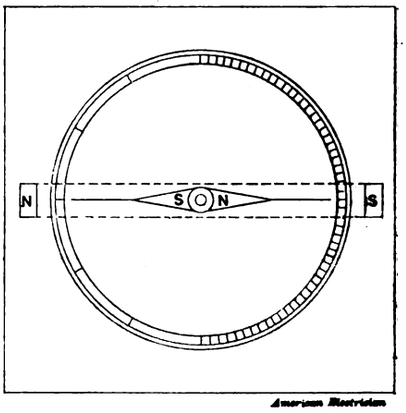
W. W. N.

## A Peculiar Arc Line Trouble.

*To the Editor of American Electrician:*

Sir—We are having a great deal of trouble with our arc line. It opens and closes several times a day. If the current is put on while the circuit is closed it will stay closed, but if the dynamo is started while it is open it will not close. The plant was installed by the Fort Wayne Electric Company and the dynamo and lights are made on the Wood system. The lamps have all been taken down and tested separately, but as soon as we begin to test the line it seems to close up.

If any of your readers have had similar experience and been able to account for it I should like to hear of it.



HERVEY SCOFIELD.

Mohawk, N. Y.

## The Testing of Armatures.

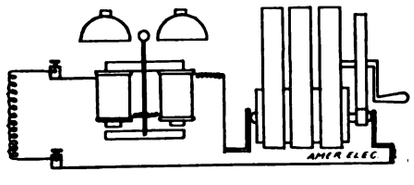
*To the Editor of American Electrician:*

Sir—Every electrician who has had to repair armatures knows how difficult is is to locate a broken connection or a short circuited coil by means of the ordinary magneto bell or other apparatus convenient in repair shops. The use of the Wheatstone bridge is quite impracticable as a rough and ready means of testing, since it requires such delicate adjustments. An open circuited coil frequently requires the unsoldering of the connections to the commutator bars before it can be located and a short circuited coil is difficult to find even when the coils are separated in this manner. A method which I have adopted and which is, so far as I know, original with me, is given as follows for the benefit of your readers.

Procure a good compass with a delicately poised needle, fit it in a square block of wood and fix in the block a small permanent magnet to give the needle a restoring force against deflecting tendencies. The general arrangement of the needle, scale and magnet is shown in the accompanying sketch, which requires no further explanation.

This instrument should be laid on top of the armature to be tested, or suspended above the same to save handling, with the needle parallel with the armature conductors. A source of direct current (either a battery or dynamo voltage through lamps) should then be connected to adjacent bars of the commutator. If the coil between these bars is O. K. the needle will be swung around violently; if it is short circuited there will be little or no movement, and if open circuited the needle will give a few slight swings, which show the current flows through all the coils on the armature. By using the proper strengths of current for armatures of different resistances and different numbers of turns per coil, the method is capable of considerable delicacy.

THOMAS BARNARD.



Toronto, Ontario.

# Electrical Catechism

*314. How can a circuit be tested by a magneto?*

The magneto consists of two parts, the generator and the bell, which are electrically connected in series with one another and with the circuit to be tested as suggested in the figure. When the armature of the generator is revolved by the crank, an alternating electromotive force

BELL MAGNETO

is generated which sends current through the circuit and rings the bell if the resistance of the circuit is not too great.

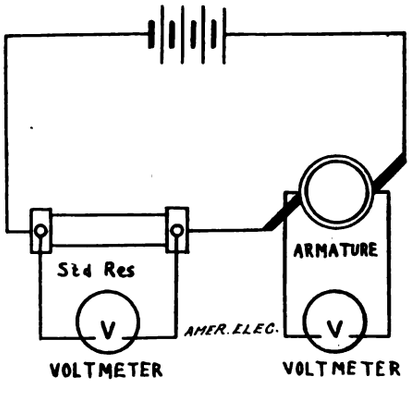
*315. How can resistance be measured by a magneto?*

The loudness of the ringing of the bells indicates roughly the current flowing. If one knows the greatest resistance through which his magneto will ring, the loudness of the ringing is a rough indication of the resistance of the circuit being tested When the bell rings almost as strongly as when the magneto is short-circuited on itself, it shows that the circuit is of low resistance. When the bell rings only feebly, it shows that the resistance is high. If the bell does not ring at all, it indicates that the resistance of the circuit is higher than the range of the magneto; in such a case, however, one should test the magneto itself to see if it will ring when its own terminals are connected directly together. As the magneto is liable to give wrong indications, it must not be depended upon too much.

*316. How can the sensitiveness of the magneto be increased?*

If the resistance is so high that not enough current will pass to ring the bell, one can detect the continuity of the circuit by putting his hands in the circuit, by putting one terminal of the magneto between two fingers and touching the back of the hand to the end of the circuit, wetting the fingers and back of hand if necessary. Turning the magneto faster raises its voltage, and so makes it more sensitive.

*317. How can a magneto give wrong indications?*



The magnets gradually get weak, so that the voltage is less, and it will therefore not ring through so high a resistance as when it was new. Again, the wires leading from it are liable to get broken, so that the bell does not ring, even if the circuit under test is continuous; for this reason, one should always test the magneto by touching its terminals together to see if it will ring on short circuit. Again, the magneto will sometimes ring when the circuit is open.

*318. How can a magneto ring when its circuit is open?*

This will occur when the circuit has large capacity, and is due to the fact that the magneto gives an alternating current. When the circuit has considerable capacity, it acts as a condenser; at each turn of the armature of the magneto, a rush of current goes out to charge the surfaces of the condenser, ringing the bell on the way; when the armature has made another half turn, the current rushes back and the condenser is charged in the opposite direction. The capacity between the frame and the windings of a large machine is enough to make some bells ring; one can feel the current through his hand even with a small dynamo, although the ohmic resistance of the insulation is up in the megohms. A few hundred feet of lamp cord has enough capacity to make some magneto bells ring.

*319. How can resistance be measured by means of a standard resistance and voltmeter?*

The circuit whose resistance is to be measured is connected in series with a standard resistance—that is, a conductor whose resistance is already known, and a steady current is sent through both. The voltmeter is connected first around one resistance and then around the other, as suggested in the figure. Since the same current flows through both con-

ductors, the voltage or fall of potential through each is proportional to its resistance, and we may write the equation: current equals voltage around standard divided by its resistance; also equals voltage around conductor being measured divided by its resistance, or

$$C = \frac{E_s}{R_s} = \frac{E_x}{R_x}.$$

From this we get: Resistance of conductor being measured equals the voltage around it multiplied by the resistance of the standard and divided by the voltage around the standard, or

$$R_x = \frac{E_x R_s}{E_s}.$$

*320. Give an example of measuring resistance by use of voltmeter and standard resistance.*

Suppose it is desired to measure the resistance of the armature of a 4 kw. dynamo. A standard resistance of 0.01 ohm is connected in series with the armature and a current of say 24 amperes is sent through both. The voltmeter shows 0.24 volt when connected around the standard. The terminals of the voltmeter are then pressed against the same commutator bars against which the brushes rest (the armature being held stationary) and the drop through the armature is measured; the armature is then turned to a new position and the voltage is again measured between the commutator bars under the brushes; this is repeated for several positions. Suppose the average is 5.0 volts. The resistance of the armature is then:

$$R_x = \frac{E_x R_s}{E_s} = \frac{5\,0 \times 0.01}{0\,24} = 0.208 \text{ ohms.}$$

*321. What precautions are necessary for accuracy in measuring resistance by standard resistance and voltmeter?*

The standard resistance must be suitable for carrying current of considerable magnitude without appreciable heating; ordinary standard resistances consist of fine wire wound closely on spools with little chance for cooling, and such can safely carry only small currents without undue rise of temperature. The "shunts" used with Weston switchboard ammeters are suitable for such use. One should be careful that the current does not change while the voltages are being measured. The voltmeter should have fairly high resistance so as not to divert an appreciable amount of current from the conductor around which it is shunted. Of course the voltmeter should give correct readings and the standard resistance should be reliable. The voltmeter should be shunted around the resistance to be measured, care being taken not to include the connections or any other resistance.

# Queries and Answers

How can I tell when a storage battery is charged to its fullest extent? J. A. E.

The measurement of the voltage is one means of telling, as the electromotive force rises and attains the value of about 2.3 volts per cell when the battery is full charged. Thus a 44 cell battery will show a pressure of about 101 volts when full charged. Another way of telling is by the "gassing." When the battery is fully charged any more current causes the evolution of bubbles, which give a continuous hissing sound, which serves as a ready indication of the condition.

We are running one dynamo, a 45-kw., to supply a maximum load of 280 amperes, station volts 130. We have two circuits (about evenly divided in load) of No. 00 wire running about 1000 feet from the station, and about ¾ of our load is within this distance, but about ¼ of the load is beyond this, scattered among the residences, the farthest being about ½ mile from the station. Within

Digitized by Google

the 1000 feet limit we deliver current to the lamps at from 125 to 115 volts, and furnish the right voltage lamps for the different customers, but beyond that distance we furnish 110 volt lamps, and at the time of full load, during the evening, of course the distant consumers do not get their full voltage, because of the excessive drop.

Under these circumstances I wish to know if it would be practicable, and would there be any saving in power to run a 3-wire circuit to supply this load, leaving two of the 00. wires for the positive and negative, and running a No. 1 for the neutral. And in this case would it be better to run the three-wire system for the supply of all the load, or only to the 1000 feet limit and beyond that use only the two outside wires, making a 220 volt circuit for the distant load?

As it is now, we have an average drop of 10 per cent. and some of the distant lamps burning below their rated voltage part of the time, while the other way we could keep the drop within 4 or 5 per cent. At present we keep tne voltage at 130 (of machine I mean) only during the heavy load of the evening, allowing the voltage to drop as the load goes down, running at 120 volts from 11 P. M. until morning.

The only additional expense for making the change would be changing the lamps and wiring, as we have another dynamo of 25 kw., 125 volts, so practically the only thing to figure would be the expense of running another machine. F. L. W.

The 3-wire system would undoubtedly be an improvement, not that there would be any material saving in power, because the added losses of running the other machine would undoubtedly amount to more than the reduction in the losses in the line, but the regulation at the lamps would be greatly improved and an allowable increase of load on the same copper would do away with the need of re-inforcing the feeders for some time to come. The idea of feeding the distant load by a 2-wire 220-volt system and the adjacent load by a 3-wire system is a very good one, as it would do away with the need of balancing the scattered residential load, a difficult thing to do, but it might be better to run the whole load on the 3-wire system in order to make it possible to shut down one machine during the hours when it is lightly loaded. This is often done by making the neutral one side of the circuit and throwing the positive and negative or outer wires together, so that one 125-volt machine delivers current to both sides of the system, on the 2-wire 125-volt plan during hours of light load. The saves the expense of running two machines at all times. The determination of whether this advantage would be sufficient to compensate for the disadvantage of making the whole system 3-wire would depend on the cost of running during the lightly loaded hours and the magnitude and distribution of the scattered loads.

What is the best way to remove all trace of magnetism in a watch? E. C. S.

The best method is to rig up a solenoid on a wooden spool with a hole bored through of sufficient size to admit the watch into the middle of the solenoid. This should be wound to a depth of about ½ or ¾ of an inch with No. 18 or No. 20 wire, the whole coil being about 6 in. long. It should be then connected to an alternating current circuit. By slipping the watch into it at one end and out through the other while the coil is in the circuit the magnetism can be easily removed. The action is due to the rapid alternations of magnetism gradually dying down as the watch recedes from the coil. The same effect can be obtained by another method with an ordinary dynamo if great care is taken. The watch should be suspended from a long string twisted many times, so that when released it will rotate rapidly. It should then be brought close to the pole of a dynamo, twisted up tight and allowed to spin while gradually removed from the dynamo to a distance of several feet. Several trials will probably be necessary to make this method effective.

How many watts are usually allowed per average candle power on arc and incandescent lights? D. U. S.

Incandescent lights generally run about 3 or 4 watts per candle-power when new and 4 to 6 watts when they have been burned several hundred hours, owing to the fact that the candle power goes down while the power used remains practically constant, thus a 16 candle-power lamp uses from 50 to 65 watts. Special lamps of a lower efficiency are made for street railway circuits and other places where the regulation is poor. Such lamps of 16 candle-power take 75 to 80 watts each. Open arc lights are generally termed 2000 candle-power when using 10 amperes at 50 volts, although their real mean spherical candle-power is only 500. Their power consumption is thus about ¼ watt per nominal candle-power and 1 watt per actual candle-power. Enclosed arcs generally run about 1½ watts per candle-power with clear glass globes, 2 or 3 watts with opalescent globes and more if both inner and outer globes are not of clear glass.

How far will telephones work through submarine cables? Will a metallic circuit increase the range, or give better satisfaction than a return through earth? If relays or repeaters could be used, how many would be required to work a cable across the Atlantic Ocean? J. A. H.

About 50 or 60 miles is the present range of clear transmission through submarine cables of ordinary construction. A metallic circuit greatly increases the range, in fact, the limit with a ground return is much less than the figure given above. If a perfect repeater were available it would require about 40 of them, spaced 50 miles apart, to reach from Newfoundland to Ireland.

Is there any prospect of improving the efficiency of a cable and any room for improving submarine telephony and telegraphy? Do any of the cable companies experiment with a view of improving the speed of transmission? J. J. P.

The greatest chance for improving both submarine telegraphy and telephony is the development of some system of distributed self-induction and possibly also slight distributed leakage by means of which the waves of current will be maintained at more nearly full strength as they pass through the cable, instead of being absorbed by the capacity. The cable companies experiment with apparatus after it has been proven on artificial cables that it may improve the working.

Are there any patents covering the induction motor? Please refer me to some book on monocyclic distribution and the induction motor. J. H. W.

The patents issued to Nikola Tesla and now owned by the Westinghouse Company cover broadly the use of polyphase currents in induction motors. Single-phase induction motors are not broadly patented, although various devices for starting them and details of construction are covered by patents. Houston & Kennelly's "Alternating Electric Currents," price $1, explains the principles you desire.

Do you know of any electric plant at present in existence whose line voltage is as high as 30,000 volts? If there is, must not unusual precautions be taken with the insulation? S. D. W.

The Southern California Power Company uses 33,000 volts on its line, 81 miles in length, supplying power to Los Angeles. No special precautions are taken with the insulators on the line, which is exposed to bad fogs and heavy rains. This is the highest voltage used commercially. The Westinghouse Company has experimented with 40,000 volts at Telluride, Colorado. At this pressure brush discharges, like those of a static machine, stream between the lines and waste quite a little energy.

How is the selenium cell made which Prof. Bell used in his instruments for transmitting speech by means of a beam of light? G. H. G.

The statement in one of our contemporaries that a selenium cell was used was in error. The receiver consisted of a delicate carbonized fibre like that of an incandescent lamp, only finer. The light was focussed upon this and the variation of its temperature changed its length, which motion was transmitted to a diaphragm. The transmitter consisted of an ordinary solid back carbon grain microphone in a special fire-proof case, connected in series with a resistance and in shunt with the arc. As the resistance of the microphone varied it took more or less current from the arc, varying the rays of heat sent out from the latter, which in turn affected the fibre at the receiving station.

How can I tap the windings to the collector rings in a Crocker-Wheeler machine for direct and alternaitng currents? W. H. S.

The collector rings can be put on the other end of the armature from the commutator. If single-phase alternating currents are wanted use two collector rings. Tap one into any coil and notice which commutator segments that coil is connected to. Tap the other collector ring into the coil connected to the commutator segments diametrically opposite those connected to the first ring. If two-phase currents are wanted add two more collector rings and connect them with coils connected to segments at right angles to those already used. If three-phase currents are wanted, use three collector rings and connect them respectively to coils connected to commutator segments 120 deg. apart upon the machine.

## A WATT-HOUR METER HAVING "MAGNETIC FLOTATION" INSTEAD OF MECHANICAL BEARINGS.

After several years of patient, painstaking investigation, study and experiment, to produce a recording watt-hour meter which should meet all the trying conditions and requirements of central station distribution, Mr. William Stanley succeeded in solving a perplexing problem.

It was intended to produce a measuring and recording device so simple as to be easily installed and cared for by any wireman without special training, durable and sufficiently strong to withstand the inevitable rough usage in transportation and handling and injury liable from short-circuits or overloads, and, withal, one which should possess a degree of accuracy and range comparing favorably with the finest scientific instruments designed for laboratory use.

It is the purpose of this article to review some of the difficulties which have been met and overcome in making a watt-hour meter combining the sensitive accuracy of such instruments with the permanency and adaptability essential in a good commercial meter, one which must be correct for all ordinary and variable conditions of any installation supplied by a central station. These conditions are difference in size of installations, in current loads, in voltages, in power factors, and sometimes in current frequency. Personal education of the wireman and inspector must be eliminated, the meter manufacturer supplying in each of his instruments an enduring standard to properly place the line of equity between the producer and consumer.

Regarded in a purely scientific light, such an instrument must undergo many and varied trials. If it is to be for general use, its capacity should be of at least five to ten kilowatts, but its service must be rendered frequently upon a demand of only fifty or twenty-five watts. It must be capable of rough treatment and remain uninjured and unaffected by it, either before or after its wooden shipping box has been removed. It must be received ready for commission without adjustment or calibration, be inaccessible to the curiously inclined, and being hermetically sealed, proof against dust, rust, moisture or any foreign substance, and finally, always ready to freely and correctly record the energy consumed by one or one hundred incandescent lamps as circumstances may require. And its duty must be performed regardless of careless setting up, unsteady supports, vibration, shock, short circuits or other hardships.

In the first meter produced by Mr. Stanley a strong driving mechanism was used and much mechanical skill was expended in perfecting the workmanship and the mechanical qualities of his product. The result appeared promising. An instrument was produced that would record current through wide fluctuations of load, that would run freely and accurately on a single lamp, and it possessed other good qualities with which engineers are familiar. This was literally too true to satisfy the desire, because together with its virtues it was likely to change through wear from continued use. It was liable to injury by careless handling. It required care and attention in setting it up, to place it level on a solid support, to release the weight of the armature, and to adjust the jewels and other mechanism. It was dependent for its good performance upon intelligent handling by a "meter man," and, worst of all, required to approximate accurate performance, annual or semi-annual cleaning and inspection.

Upon examining the situation critically it appeared that the fundamental frailty of this meter was in the main bearing or support of the driving mechanism, and the advance was to be made in perfecting this part. A careful study of the conditions of induction (alternating current) watt-hour meters revealed the fact that they were highly accurate, provided a perfect, frictionless bearing could be devised; but in the nature of their construction, vibration was particularly severe on the best constructed bearings available. An alternating current flux, such as all induction watt-hour meters employ, causes a slight vibration or trembling of the driven part or armature of the meter, and experience soon proved that this slight trembling, caused chiefly by the shunt, which, in watt-meters, is constantly in circuit, caused a rubbing or wearing between the armature staff and its supporting bearing, and that this rubbing, constantly applied at the rate of 7200 or 16,000 thrusts per minute (according to the frequency of the current employed), rapidly destroyed any bearing that has been devised.

Mr. Stanley's next experiment was to make the armature or driving mechanism so light that the weight to be supported by the bearing could not injure a polished, blunt, hardened steel staff on a good sapphire stone. The argument that a meter disc as light as a feather could not injure the bearing was very fascinating, and following this line some beautiful models were produced with hollow, seamless aluminum staffs, the walls of which were only three or four one-thousandths of an inch thick, and pivots in the ends of this staff were made of short pieces of steel as small as an ordinary needle and less than a quarter of an inch long. The practical results were disappointing, for destruction of the jeweled bearings and staffs was caused by the continued trembling thrusts recurring at the same rate as the alternating current frequency and similarly to the wearing away of stones by dropping water, or the constant treading of feet. And in the end an accidental short-circuit demolished a handsome and expensive model by sending the meter disk out of the case upon the floor.

The next line of experiment devised was to support the moving element of the meter upon a hollow ball, floated in a light liquid or oil contained in a vessel made after the plan of the "non-spillable" ink bottles. This oil supported the armature, while it was held vertical and central by small sapphire guide rings surrounding the staff. This apparatus soon took its place with its predecessors on the model shelf, but it served the useful purpose of illustrating the extreme delicacy that is essential in a good and enduring meter bearing.

The next model, of which there were several forms, for a time promised better results. It finally took the shape of a very light, accurately made aluminum cylinder, open at the bottom and closed at the top by a flat wooden head made of three layers of wood glued together and having a total thickness of less than three one-hundredths of an inch. The cylinder was then mounted vertically upon a staff passing through the wood, which was to serve two purposes: First, to make a support by which the cylinder could be mounted and balanced in a vertical position, the passage through which support of no upward strain of magnetic lines could cause vibration; second, the wood in a small circular disc when spun around by the aluminum was designed to serve as a deadener of vibration in the latter and to prevent the transmission to the pivot and supporting sapphire jewels of any destructive rubbing produced by alternating magnetic impulses. Furthermore, the entire alternating magnetic cores for the shunt and series circuits of the meter were placed by an ingenious construction entirely within the aluminum cylinder, and so arranged that every thrust due to induction was balanced by equal thrusts on the opposite side of the cylinder, so that a completed driving armature consisted of an aluminum cylinder supported by a wooden head and driven entirely by induction from the inside, and equally applied in opposite directions. A perfect armature constructed after this plan, with ample mechanical strength, weighed, including the supporting staff and driving pinion, less than ¾ of an ounce. It seemed that this model achieved the limit of perfection in mechanical construction, strength and electrical balance, but, like its predecessors, it failed under critical tests of continued service. These were the best results accomplised at the end of very nearly two years of very close and careful work, the thoroughness and extent of which are scarcely hinted at in the foregoing.

The conclusion expressed by the experimenter was certainly discouraging, namely, that in his judgment no mechanical bearing could be found which would withstand the wear and rubbing caused by the slight, and, under some conditions, almost imperceptible vibration by the alternating fluxes in the armature of an induction watt-meter. That, while various devices could be employed to prolong the life of induction meter bearing, a real endurable bearing cannot, or at least has not, been produced. And it was when forced to this conclusion that Mr. Stanley produced a meter without a meter-

Digitized by Google

bearing, and having no friction (except a very slight dial-train friction), and, therefore, no wear. This result he has accomplished by "magnetic flotation," and its practical application is embodied in a watt-hour meter here illustrated. Fig. 1 is an outside view of the instrument, showing the meter in its substantial air-tight case, the cover of which is secured by four heavy case-screws, which are covered with seals, at the corners.

Fig. 2 illustrates the interior of the assembled meter, the plan of "magnetic flotation" and permanent magnet brakes.

The flat aluminum disc or armature is mounted in a careful mechanical balance on a soft steel core. This core is held central in recesses in the iron pole pieces by polished, hardened steel staffs passing through phosphor-bronze guide rings. The pole-pieces themselves are magnetized by the permanent tungsten steel magnets of such polarity that the upper pole-piece and the inverted flat-head screws set therein are of opposite polarity to the bottom pole-piece and similar screws which are below the disc.

The magnetism established by the permanent magnets is made to serve a double function. It lifts and supports the soft iron core and the aluminum disc thereon mounted, to a definite position between the pole-pieces free from mechanical support, and also supplies the necessary flux threading the disc between the brake-screws to serve as a magnetic brake controlling the speed of the disc.

The series and shunt-coil windings are entirely enclosed within the meter case and separated from the permanent magnets and the magnetic flotation parts by a magnetic shield with a narrow slot through which the disc revolves. This device prevents any weakening of the permanent magnets by excessive currents in the meter. The series coils are of especially durable construction and consist simply of a few turns of heavy flat copper strip wound up with a thin strip of asbestos paper between the turns, so that there is no cotton or other combustible insulation upon them to be injured by excessive current.

As every detail of design and construction has been carefully worked out, and only the best attainable results are embodied in the Stanley watt-hour meter, attention is directed to the peculiar shape of the two permanent magnets. Iron bent after rolling has a tendency to unbend, and its shape is gradually changed. As the distance between the poles of the magnets must remain constant to secure proper "damping" or brake effect upon the disc, to obtain the best results it is essential that their ends be rigidly secured, and change of the air-gap, due to expansion or contraction, prevented. In the magnets and supports here illustrated this has been accomplished in an admirable way. Annealed, cast-iron pole-pieces are carefully made with planed faces into which the magnets are fitted and rigidly fastened by heavy screws. The pole-pieces are in turn securely screwed to a brass bracket, and the whole supported firmly upon the iron bracket. This effectually prevents any movement of the magnet poles which, remaining in a fixed position relative to the disc, exert a constant and uniform effect upon it, and thus eliminate the error so often caused by permanent magnet brakes changing by reason of a change in the air-gaps of the magnets.

The performance of the meter is quite as interesting as its construction, and with 25 watts current on a 5 kilowatt meter, the error of registration is less than 2 seconds in 120. Furthermore, the speed of the meter on 25 watts or 5000 watts would be the same whether the meter were properly connected to run forward, or improperly, to run backward; and the rate of every meter before leaving the factory is tested at backward rotation under a load of one per cent. of its capacity to determine the backward and forward rate under these conditions. Consequently the meters must be free from friction and in mechanical and electrical equilibrium, making it impossible for the meter to run or "creep" on the shunt current when there is no load on the meter.

The meter demonstrates the feasibility of constructing a large-size instrument that will run freely on one-half of one per cent. of the current which it is designed to measure, and which will record accurately one per cent. of its rated load, and will do so without compounding the meter or providing an initial starting tendency, as is sometimes done, with the unsatisfactory result of frequent "creeping" on the shunt current, especially in locations where there is any vibration.

It has been shown by what means the Stanley watt-hour meter is constructed to accomplish the purpose of a meter that cannot change by wear, that can be installed by an ordinary wireman, that cannot be tampered with without breaking conspicuous seals, that will stand much rough usage, both mechanical and electrical, without injury, and, withal, records the current passing through it with a degree of accuracy and extent of range hardly equalled by the most delicate scientific laboratory apparatus. The success of the engineering design is best appreciated when the fact is considered that these meters are not made in smaller sizes than 50 amperes (or 100-light) capacity, and yet they are sold under a guarantee of a long period to record correctly on 25 watts current or a single 8 c. p. lamp.

## THE CONSTRUCTION AND PERFORMANCE OF MILL MOTORS.

The distinguishing features of the machines described below are their exceptional operating characteristics, protective forms and controlling mechanism, which fit them particularly for all work requiring either great momentary turning power, safety from external injury or convenient automatic starting and stopping. Dynamos and motors were made, at first, in the ordinary or open forms and of very high speeds. Afterward, others of medium speeds, and of very slow speeds for direct connection were produced, and now motors of still other types, having the characteristics described above, are demanded. To meet this demand the line of machines here described has been put on the market by the Crocker-Wheeler Company, Ampere, N. J.

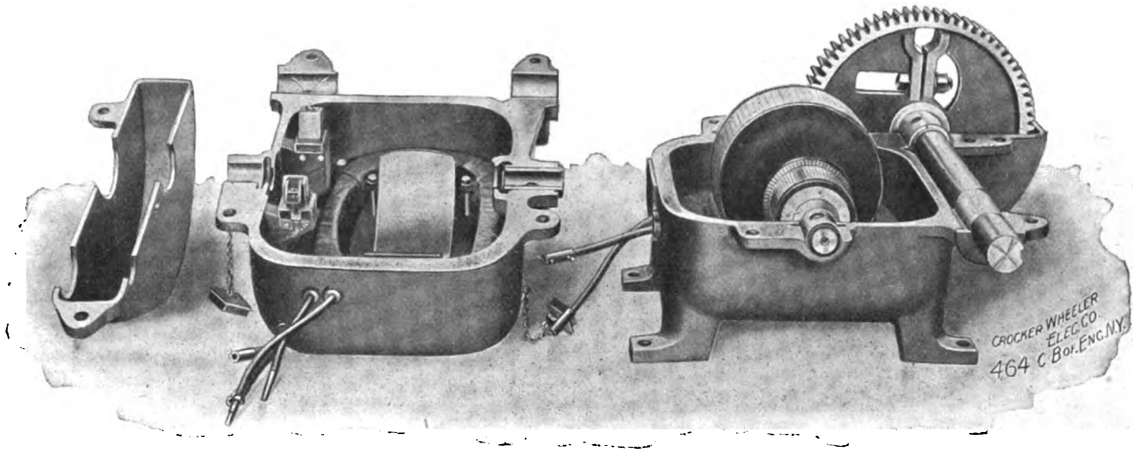

FIG. 1.—MILL MOTOR DISASSEMBLED.

Mill motors consist of iron-clad armatures, encased in cast steel boxes nearly the shape of round-edged cubes, which form the field frames.

This construction, however, prevents ventilation, and precludes their use for continuous running at full load on account of their heating up. Mill motors with back gearing are practically the same as railway or car motors, which they closely resemble. By omitting the feet, and by extending both ends of the countershaft so that wheels can be mounted on them, small car motors are made suitable for industrial railways.

The armature cores are slotted. The slots have parallel sides with rounded bottoms; the openings at the top between the teeth are the full width of the slots in order that the coils may be slipped into them from above. They are narrow and the length of the air gap is so proportioned that eddy curents in the pole pieces are avoided. The cores are built up of soft sheet iron, the laminae being insulated from each other by a layer of oxide, formed during the annealing process, and by a sheet of paper after every fourth disc. The armature being of small diameter, the discs are each made in one piece with a hole in the center to fit closely the shaft and its key. The core and commutator are mounted directly on the shaft without the intervention of a spider.

The envelopment (winding) is of the "drum" form and is connected for "two circuits." The coils, consisting of insulated wire, are wound separately on forms and dipped in insulating varnish. They are then encased in two layers of cambric. The portion of the coil which is to lie in the slots is wrapped in four layers of oiled muslin and two of rubber tape. The slots are prepared by lining with two thicknesses of oiled muslin and two of press-board, and the coils are slipped into them. After connections are made to the commutator, canvas heads are put on the front and back of the armature, affording additional protection. The field coils also are wound separately on forms, and "mummified" wth numerous layers of cambric, oiled muslin, rubber tape and paint. They are then placed in position on the salient pole pieces and held there by metal clamps, no field spools being used. This construction makes the windings practically impervious to moisture and dust and, therefore, adapted for use under the most trying conditions wthout risk of injury.

The frames have inwardly projecting poles and are divided horizontally through the axis of the armature into two parts, as illustrated by Fig. 1. The sizes 22 and 6, which have four poles, have those at the sides split by this division, and, therefore, these poles are not provided with coils, but are made consequent, the fields being energized by the coils which suround the other poles, that are above and below the armature. The bearings are rigid instead of self-aligning, this form being stronger for heavy work. The journal boxes are divided horizontally, the lower halves being seated in projections of the frame. A heavy grease which will run through a small hole when warmed by friction, is contained in a grease cup over each bearing.

Relation of Speed and Torque.—In their operation, mill motors differ essentially from belt type machines, in these particulars: When slowed down or started from a state of rest, they are capable of exerting a turning power many times greater than that given at full speed.

Like a horse, they slow down and redouble their effort when required to move a heavy load, while belt type (shunt wound) motors do their work at full speed and in a manner similar to that of a well governed steam engine, whose best work is at full speed and which is incapable of increased effort at reduced speed.

The efficiency of mill motors is a little lower than that of belt type machines, because they are designed to have certain other characteristics in a marked degree by its sacrifice. That obtained at starting and at low speeds is small, because the losses are nearly as great as at any time, while comparatively little power is developed, although the machine makes a great starting effort. At middle speeds, the efficiency is the highest, because the product of torque and speed, which is the output, is at a maximum. It is lower again at high speeds, as the torque is reduced so much by the light loading and the effect of the series winding, that although the speed is very high, their product, or the output, is less than before.

These characteristics of speed, torque and efficiency may be examined in detail in the curve, Fig. 2, from which the actual values may be read, as the curves were plotted from tests of machines.

The heating standard is 55° C. rise above the temperature of the surrounding air after one hour's continuous run, or 10° higher than that adopted for open motors, whose ventilation is good. In enclosed motors there is no ventilation, but this rise in temperature is not dangerous to the insulation. It has the recommendation of the Standardizing Committee of the American Institute of Electrical Engineers.

Heating Time Average.—As has been pointed out mill motors, being enclosed, are liable to excessive heating if run continuously at full load. Being designed, however, for intermittent work only, this is unimportant, and the limit is seldom reached on account of the character of the work for which they are employed, which allows intervals for cooling. In consequence of this the temperature rises only

Digitized by Google

to correspond with the amount of time the motors are used under load. Therefore, the determination of the "time average in heating" is important. If the machine retained all its heat when the current was applied—losing none—it would heat up rapidly at a uniform rate, as indicated by the dotted straight line, Fig. 3, reaching the maximum alowed for safety in a very short time. A hot machine when allowed

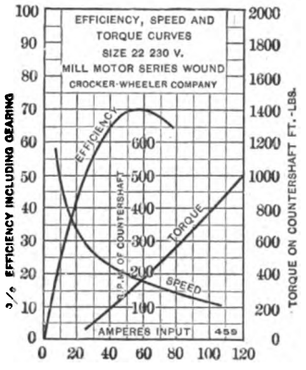

FIG. 2.

to cool, cools rapidly at first and more slowly afterward as its temperature reduces; because, then, there is less difference between its temperature and that of the surrounding air to induce the transfer of heat from it to the air. Its rate of cooling is, then, rapid at first, and slower afterward, finally extending over a number of hours as the temperature reaches almost that of the air, as indicated by the dotted line which slants downward to the right in the diagram, and by the other shading lines which are duplicates of it and represent the same rate of cooling started at different periods of time.

These curves cover the principles involved in the determination of the temperature which a machine will reach under any conditions of use. Applying them to a machine intermittently under a full load, we see that when it is started it will heat up in accordance with the solid curve for as long a time as it is used, and will, when stopped, commence to cool off from that temperature, following the shading line of the diagram representing the rate of cooling off. When started again it will resume heating up from this new point, and heat up again as long as in use, following a section of the corresponding curve of heating, and when stopped will again cool off in manner corresponding to the curve of cooling, and so on. In the diagram the machine is represented alternately in use ten minutes and idle twenty minutes. It will be seen that when the machine's temperature is low, the heating with use is rapid and the cooling off slight. As the machine becomes hotter, say after the second hour's use, the heating amounts to less and the cooling off to more. The machine will finally reach a temperature as high as will be necessary to cause it to cool off in twenty minutes as much as it heats in ten, but lower than its maximum temperature for continuous use.

If the conditions of a machine's load are known in advance, the proper size to install can readily be determined by means of these curves. For instance, if it is to be used only five minutes every half hour, a smaller machine may be used than if its work keeps it running ten minutes out of every fifteen.

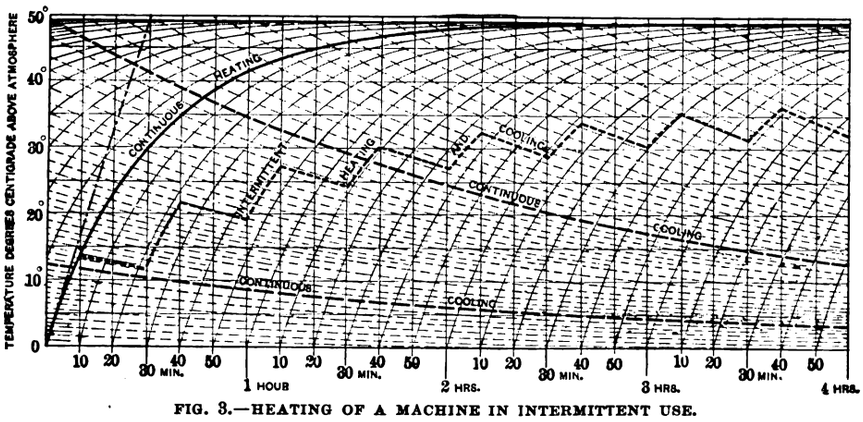

FIG. 3.—HEATING OF A MACHINE IN INTERMITTENT USE.

## THE INSURANCE OF ELECTRICAL MACHINERY.

The general principle of insurance is designed to protect property owners against sudden and unexpected losses, generally of a magnitude too great for them to meet, the risk of such losses being taken by comparatively wealthy organizations, known as the insurance companies, who depend upon a system of averages for their compensation. Another condition of proprietorship on which insurance is desirable is the ownership of machinery or apparatus which the owner does not understand and in the care and maintenance of which he is therefore more or less helpless. He can, to be sure, engage employees who are presumably competent to attend to the apparatus, but owing to his own lack of knowledge upon the subject this presumption may be and often is a mistaken one. The employee is, at the best, not entirely responsible for the apparatus under his care and may shift the responsibility, in case trouble comes through his incompetency. In case repairs or renewals are needed the owner is more or less at the mercy of those who must undertake the work, owing to his lack of exact knowledge as to what is needed. On this acount the existence of a company which would step in and assure the maintenance of his machinery in proper running condition for a given sum, would prove to many an owner of such machinery a great boon. Such a company is The Maintenance Company, of 220 Broadway, New York City.

This company enters into a contract with its patrons, guaranteeing them for one year against any losses on account of failure of or accident to their electrical machinery, exclusive of wiring. The scope of the insurance is about to be extended to cover gas, steam and other machinery. Differing from other companies which have engaged in similar lines of business in the past, The Maintenance Company does not operate a repair shop, but renews, at its own expense, all parts when required with duplicates from the original manufacturer; patch work is thus avoided, the machine is maintained in practically as good shape as new, patent rights on details of construction are not infringed, and the good-will of the manufacturers is retained as they lose no business, in addition to which they feel no risk of their machines being repaired by unskilled men.

Naturally The Maintenance Company, after issuing such a guarantee, takes care that the apparatus is kept and attended in such a way as to avoid failures and break downs, the expense of which the company must assume. The company therefore has a corps of expert inspectors who have at their disposal the best of instruments for the making of tests and who are directed to regularly inspect the machinery and see that it is in the care of competent men. The inspectors also act as instructors to the engineers and help them in case of trouble which they do not understand.

The company was organized with a capital stock of $100,000, which is fully paid in, part of which is deposited with the Colonial Trust Company as a trust fund against which each contract is a claim. This trust fund is maintained at about 75 per cent. of the total premiums written. A large part of the company's business is obtained from manufacturers themselves, who, instead of guaranteeing their machines for one year, turn over this feature to The Maintenance Company, the guarantee to the latter being, of course, of greater benefit to the user of the machinery than is the manufacturer's guarantee, as the latter is, as a rule, solely applicable in case any trouble which occurs can be proven to be due to an original defect, while the guarantee of The Maintenance Company is against all trouble. As the guarantee for the first year is, as a rule, extended by the user of the machinery, the company can well afford to make attractive rates to the manufacturers to induce them to turn over this troublesome feature of their business. The company now has something over 1000 machines under contract, largely in isolated plants.

The officers of the company are as follows: Jas. J. McKenna, President; Joseph M. Cooper, Secretary, and Ernest R. Bartlett, Treasurer.

## AN ELECTRIC SUPPLY HOUSE AND THE WAY IN WHICH IT IS CONDUCTED.

ONE of the largest of the supply or jobbing houses that have come into existence to meet the demand for the many appliances used in electrical engineering is the Electrical Appliance Company of Chicago. In this connection should be noted the difference between the meaning of the words "appliance" and "machine." The former applies to a part of a machine or an accessory that assists the machine to render its service, while the latter word is the name of a device that orginates its own action or produces something. Using this distinction it may be noted that this house deals chiefly in appliances, unless an electric fan can be called a machine.

The building shown in the initial letter, to which the business of this company has recently been moved, is a five-story brick structure with basement, located on the corner of West Van Buren and Jefferson Sts., and has a ground dimension of 50x100 feet, giving about 30,000 square feet of floor surface. The stock includes everything listed in a general catalogue of electrical appliances, embracing those for street railways, electric lighting plants, telephone outfits and telegraph sundries. In the telephone department the company manufactures its own telephones, the type being a distinct or standard make. One of the distinguishing features of this telephone is the design of the transmitter, which is moisture-proof, and is constructed with a diaphragm of either carbon or metal, while the granules are chemically treated, producing a sensitiveness not generally found in telephones.

The first floor of the building is occupied by the offices of the managers, offices for the clerical force and at one corner is the retail department, which carries a large assortment of shelf goods. The rooms are provided with labor-saving appliances to facilitate the dispatch of business, among which may be noted a half dozen or more graphophones, to which the chiefs and others dictate all the correspondence, which is afterward written out by a corps of typewriters.

The rear portion of the first floor is utilized as a shipping department, from which an electric freight elevator connects with the basement and upper floors; while there is a small dummy elevator for transmitting orders, and, when necessary, the smaller items of stock. Included in this department is also a telephone exchange, with an attendant having wires connecting with each room of the building and two trunk lines to central. Besides this there is an interior telephone system connecting the different departments.

The basement is occupied by heavy material, including galvanized wire, a stock of interior conduits, including both the wood lined and loricated, together with crossarms and linemen's heavy tools. On the ground floor brackets, light constructing tools, including reels and stretchers, are stored in suitable bins and racks. On one side is a large platform for carrying the rolls of covered wire and here is also carried a stock of lamps in original packages and also the fan motors.

The third floor is similarly equipped and filled with magnet wire, porcelain and clay insulating goods and other wiring sundries, while at one end of the same floor is a telephone assembling shop, which is equipped with a number of metal working tools, operated by an electric motor.

A portion of the second floor is occupied by a stock of lamp sockets, switches and cut-outs, and at the rear of this floor is the packing department. This is provided with packing counters and bins, which are numbered and lettered. One of these divisions or bins is devoted to each order and all the items of that order are assembled in it for packing.

This company was organized and began business in 1891 on the first floor of a building at 242 Madison Street. In the following year it occupied the basement in addition to the ground floor, and the third year after beginning business the entire building of three stories was required, aggregating 3,000 square feet. This being outgrown last spring, the business was moved to the present quarters, having a floor capacity three times as great as the former building.

The affairs of the company are under the direction of Mr. W. W. Low, Pres.; Thos. I. Stacey, Sec. and Treas., both of whom give their entire time to the supervision of the extensive business. They employ a number of local and traveling agents and have resident agents in St. Paul and New Orleans, so that their custom comes from all parts of the country, as well as Mexico and South American countries.

FIG. 5.—MACHINE SHOP—TELEPHONE DEPARTMENT.

## THE ANNUAL REPORT OF THE ELECTRIC STORAGE BATTERY COMPANY.

The enormous increase of the business of the Electric Storage Battery Company is shown in the annual report of President Rice, recently issued. The sales during the year 1898 amounted to $1,340,968, as against $1,026,926 for the preceding year. For the first five months of 1899 the sales amounted to $1,360,561, as against $314,499 for the same period in 1898.

The treasury resources of the company, after providing for all bonded and floating indebtedness, are given as $10,218,374. The report states that the company owns 5/12 of the automobile business formerly controlled by the Electric Vehicle Company and the Columbia Automobile Company, which have consolidated under the name of the Columbia and Electric Vehicle Company. The Electric Storage Battery Company is also closely associated with the Illinois Electric Vehicle Transportation Company, which has bought the Siemens & Halske electric plant in Chicago. This plant will be devoted to the manufacture of electric vehicles.

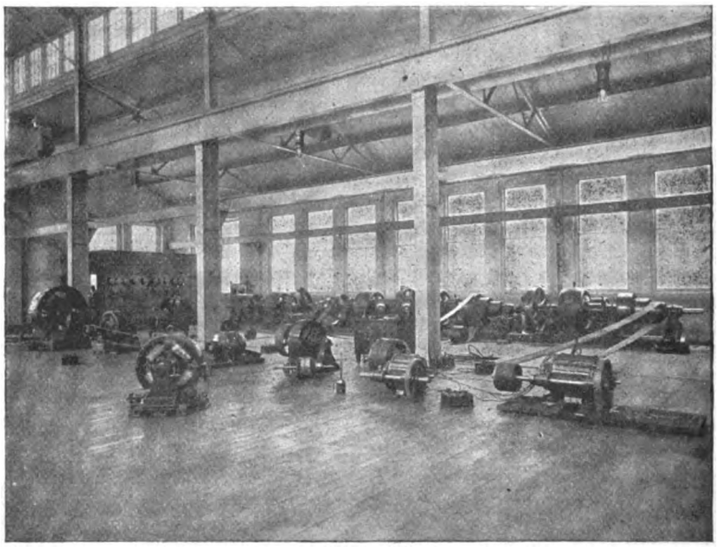
## A MODERN PLANT FOR THE MANUFACTURE OF DYNAMOS AND MOTORS.

An example of the advance which is being made in the large manufacturing establishments of to-day is the new manufacturing plant of the Bullock Electric Manufacturing Company of Cincinnati, Ohio. This model plant was completed last summer and the Bullock Company moved in the first of the year. The buildings are located at East Norwood, Ohio, one of the suburbs of Cincinnati and less than five miles from the heart of the city. The B. & O. S. W. Railroad crosses the Pennsylvania Lines at this point and both roads have tracks entering the works giving the company exceptional freight facilities.

The several buildings are constructed of light yellow pressed brick with appropriate trimmings of stone, and are massively well built; they are separated from each other by grass plots, flowers and shrubs. Great windows are a feature of every building, and such a thing as dim light is entirely lacking in office, machine shops and power house.

The plant comprises the administration building, machine shops, foundry and power house. In the first mentioned are the general offices, drafting and pattern rooms, lunch room for officers and heads of departments, with a completely equipped kitchen and pantry, general lavatory and locker rooms for workmen and a well appointed stable. In the main hall of the administration building is an office of the Postal Telegraph and Cable Company, with an operator in charge, and a miniature telephone exchange with lines extending to the various departments. The drafting and pattern rooms are on the second floor of the building and are very light and commodious for the large forces employed. Kitchen and lunch room are home-like in equipment and decoration, and the stable in the rear is above criticism.



THE MACHINE SHOP.

The Bullock shops illustrate the great economic progress made in manufacturing methods during the century, or, more properly speaking, during the past quarter century. Long lines of shafting and counter-shafting; cumbersome, unsightly and light-forbidding belting, noisy, dirty and costly, all characteristic of a method of applying power soon to be, if not already, obsolete, are missing; and one is deeply impressed with the improving difference as a result of the application of independent electric motors for power purposes. Each machine in the Bullock shop has its own motor, which furnishes power when, and only when it is required.

The motors used for driving the various tools are especially designed and adapted for the tools driven, being built—in the case of the lathes—directly in the head stock, and in other tools taking the place of the driving pulley and requiring no more room. The motors are of the slow-speed type with the variable speed control governed by the multiple voltage system, which enables them to operate their tools in six varying speeds in either direction without the use of back gearing or any resistance whatsoever in the electrical circuits.

The main machine shop, all on one floor like every other building of the plant, is divided into the following departments:

THE TESTING DEPARTMENT.

The winding room, where the armatures and fields of the machines are wound and insulated; the coils of the armatures being machine formed before being placed in the slots of the armatures; the testing room, where the finished machine is tested to its fullest capacity during an entire day's run, to ascertain whether it fulfills the standard called for in the company's apparatus; the erecting shop, the machine tool shop, the commutator and brass finishing shop, where the commutators are put together, and where the brush holders, bushings and terminals are completed; the tool room, the punch department, where the armature discs are punched out of sheet metal and properly notched and the pole pieces punched and put together, and the stock room.

Last of the buildings to be described is the power house. The boiler room contains vertical water-tube boilers fitted with furnaces having moving chain grates; consequently the tall chimney of the plant is smokeless. The engine room contains a cross-compound engine direct connected to two of the Bullock Company's engine type generators, which supply current not only for the lighting system but for the multiple voltage power transmission used throughout the entire plant. A section occupying the whole southerly end of the building is set apart and fitted out for the employees' lunch room.

The officers of the Bullock Electric Manufacturing Company are: George Bullock, President and Treasurer; J. S. Neave, Vice President, and James Bullock, Secretary.

# New Apparatus and Appliances

### A SHUNTED FUSE SWITCH.

Those who have experienced or are experiencing difficulty in opening high tension circuits will be interested in a description of the new shunted switch, which is being placed upon the market by the D. & W. Fuse Company, Providence,

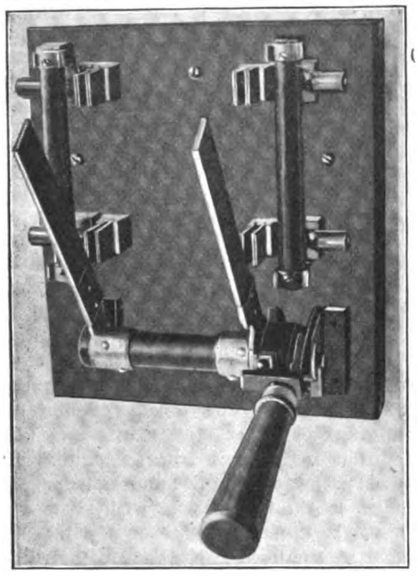

FIG. 1.—A NON-ARCING SWITCH FOR HIGH TENSIONS.

R. I., as by this device circuits of almost any potential may be successfully opened without the burning of the switch blades or any objectionable discharge.

The principle of this device, as the name implies, is the simple shunting of the blades of a novel quick make and quick break switch by one or more of the well-known non-arcing D. & W. fuses of small capacity.

By this means the actual opening of the circuit does not occur at the instant the switch blades leave the jaws, the current being shunted through the fuse, which operates an instant later than the blades, the actual opening the circuit taking place within the fuse.

The blown fuse is then removed by simply drawing it out from the spring clips, the new one not being inserted until after the switch has been thrown in circuit again, or it may be inserted just prior to the time when it is necessary to open the circuit.

Although, of course, every time the switch is opened a fuse is blown, these fuses are designed so as to be readily reloaded at a very small cost, there being no necessity for the use of solder, the company supplying the material for the refilling, which may be done by the regular station attendant.

Fig. 1 shows a 50-ampere double pole 2500-volt switch of this type. These switches have been repeatedly tested on high potential inductive circuits, having heavy lagging currents, where they have operated, it is claimed, with the most perfect satisfaction in every instance, it being impossible to detect any flash or flame at the instant of opening, the fuse operating quietly and without disturbance.

### AN AUTOMATIC REGISTER OF TELEPHONE CALLS.

The message rate system now generally adopted by large telephone companies involves considerable extra work on the part of the exchange operators in the writing of a ticket each time a call is made, giving the calling number, the time and the number called for. An automatic means of accomplishing the same result would considerably increase the capacity of the operators for handling business. Mr. H. T. Richards, 225 W. 28th Street, New York City, has patented a register which automatically indicates at

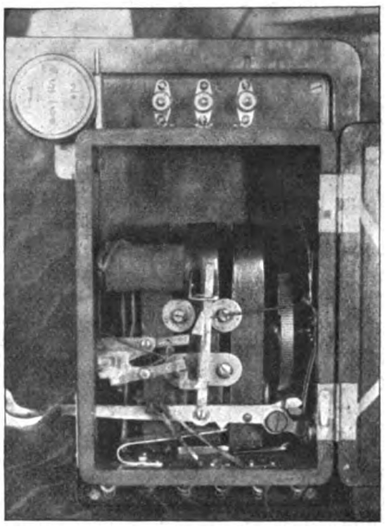

FIG. 2.—THE REGISTER AT THE SUBSCRIBER'S INSTRUMENT.

the subscriber's instrument as well as at the exchange, whenever a call is made. This is accomplished by means of a grounded circuit passing through an electrically operated register for that particular subscriber's line located at the exchange, thence through one wire of the metallic circuit to the apparatus of subscribers' instrument, shown in Fig. 2. At this point the ground circuit passes through an extra contact on the hook switch so designed that the ground connection is only made when the receiver is off the hook. The apparatus is actuated by the exchange operator, who closes the circuit while the instrument is in use and the telephone therefore off the hook. This operates the register at the exchange by means of an electromagnet and fastens the hook switch at the subscriber's instrument to the register, so that when the telephone is replaced on the hook the register is moved ahead. Thus the register can only be advanced while the telephone is in use and yet it is not automatic, and consequently recording all calls whether they should be paid for or not.

### A RINGING GENERATOR ACTUATED BY BATTERIES.

The Eureka Electric Company, Chicago, Ill., is placing upon the market what is known as the Eureka central energy generator. This piece of apparatus, which is shown in Fig. 3, is especially designed to take the place of hand generators in telephone exchanges where power for driving generators is unavailable or where the cost of such driving is so high that a cheaper means of ringing is desirable. Four cells of any ordinary type of salammoniac battery gives the power which the apparatus shown in the cut converts inductively into a high voltage and sufficient quantity to ring bells over lines having resistances as high—it is claimed—as 100,000 ohms.

Unlike some battery driven generators designed in the past, the vibrator only runs when it is desired to signal a subscriber, in consequence of which the batteries are not exhausted when the apparatus is not in use. The circuit is closed either by a cam lever upon the Eureka metallic express switchboard or by a foot push, which is furnished with the machine for use upon other boards. The instrument is adapated for either series or

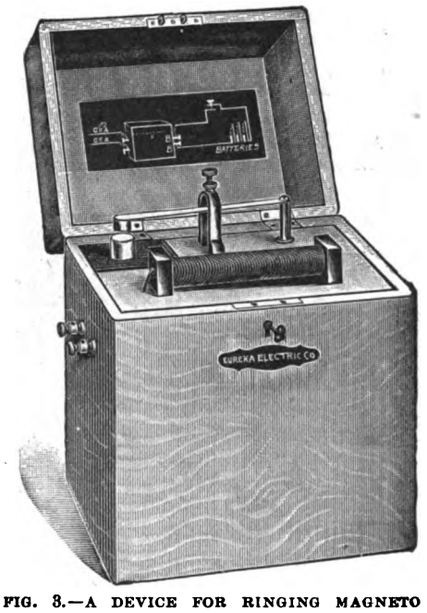

FIG. 3.—A DEVICE FOR RINGING MAGNETO BELLS WITH BATTERY CURRENTS.

bridging lines. Its size is 10x12 ins. and it can be placed wherever convenient, either at the switchboard or away from it.

### A SIMPLE MOTOR STARTING BOX.

As many of the authorities no longer require motor starting boxes with an overload release the C. & C. Electric Company, New York City, has put on the market the type "A" starting box, fitted only with a low-voltage releasing device, the simplicity of which can be readily seen from the illustration, Fig. 4. The box

Digitized by Google

consists simply of a case of cast-iron containing the resistance coils wound on asbestos tubes, and a face plate of polished slate to which are bolted the removable brass contacts, the contact lever, with its spiral spring, and the iron-clad release magnet. The winding of the latter is

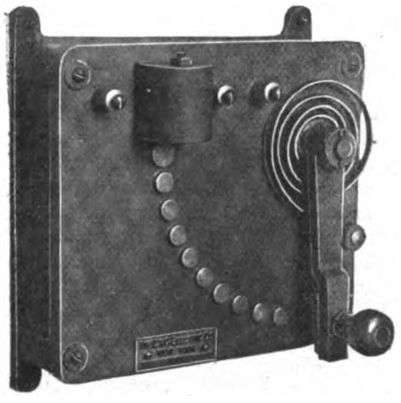

FIG. 4.—A MOTOR STARTER WITH UNDER-VOLTAGE RELEASE.

connected in series, as usual, with the motor field, and its poles engage and hold an armature attached to the contact lever when the latter is in the running position.

---

AN AUTOMOBILE WITH BOTH GASOLINE AND ELECTRIC MOTOR DRIVING EQUIPMENTS.

By combining the gasoline engine with an electric motor for vehicle driving the engine can be made lighter than that required to alone drive the vehicle up the heaviest grades. The disadvantage of poor starting apparently inherent in the gasoline engine can be entirely overcome, and the motor and battery can be made much lighter than though they alone were required to supply the full power, as the battery is alternately charged and discharged at short intervals from the engine and is not dependent upon power houses for charging current.

A line of vehicles driven in this manner has been put on the market by the Munson Company, La Porte, Indiana. The driving gear upon these vehicles is shown in Fig. 5. The engines are horizontal and of the twin cylinder type, with balanced cranks and electric ignition. The igniters are supplied by the storage battery of the dynamo and fitted with spark coils specially wound for the high pressure, 40 volts. To prevent the grounding of the circuit both contacts of the igniters are insulated from the engine castings.

Coupled to the engine shaft is the generator or motor, which is of the external armature type, narrow and of large diameter in order to obtain maximum flywheel capacity with a given weight. The dynamo has a ring armature with a series or two circuit winding and a radial or disc commutator. The internal field has six poles energized by a single field coil, shunt wound and divided electrically into two halves, connected respectively to each of the two trays of storage cells, so that the series multipling of the trays does not affect the field excitation. The dynamo is enclosed in a dust and moisture-proof casing.

Two sizes of dynamos have so far been made, one rated at 3 h. p. and the other at 5 h. p. The smaller machine has a speed of 360 r. p. m. when running free on 80 volts; its weight is 300 lbs. and its dimensions are 18 ins. external diameter by 8½ ins. width over all. The larger machine has the same speed, slightly larger dimensions, and its weight is 425 lbs.

By means of the controller the two trays of the battery can be connected either in series or parallel, giving to the motor two speeds, one double the other as the machine is shunt wound, and a further speed variation is obtained by means of a changeable gear. This gear is changeable in a ratio of 4 to 1, so that there are two speeds on each gear, giving 4 speeds to the vehicle altogether. A reversing switch is used for backward movements by means of the motor alone, there being two backward speeds. There is one resistance position of the controller, with the batteries in parallel, and also one when they are in series, but the controller mechanism is not fitted with notches in these positions.

With the larger sized motor two makes of battery have been employed, one outfit weighing 800 lbs. and rated at 100 ampere hours at 80 volts; the other weighing 650 lbs. and rated at 75 ampere hours at the same pressure. Owing, however, to the quick recharging of the battery as soon as the driving of the vehicle requires less power than the engine generates, it has been found that a much lighter battery can be used and give proper results. Both pleasure vehicles and delivery wagons have been built with driving gears of this kind.

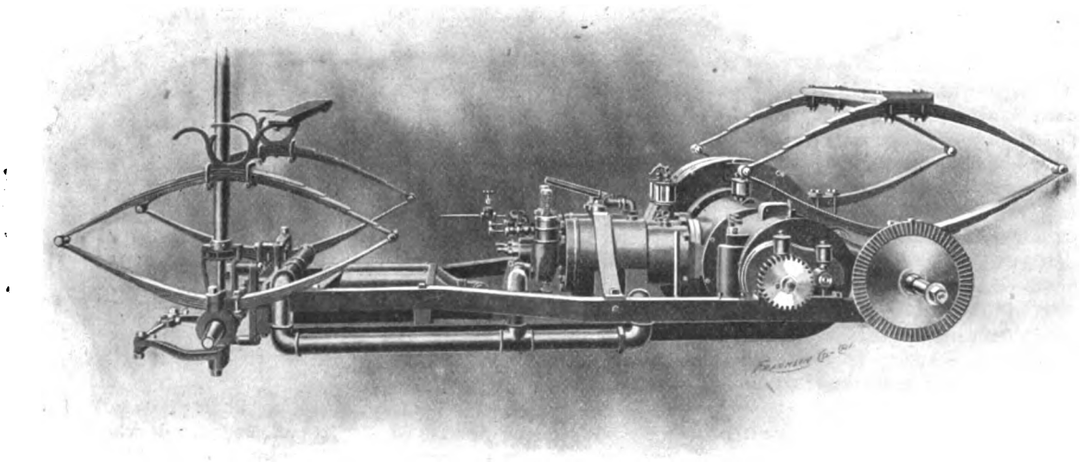

FIG. 5.—A COMBINED GASOLINE AND ELECTRIC MOTOR VEHICLE EQUIPMENT.

---

THE SUSPENSION OF THE PITTSBURGH TRANSFORMER.

The type "K" transformer made by the Pittsburgh Transformer Company, Pittsburgh, Pa., recently described in these columns, has been provided with a convenient form of suspension shown in Fig. 6. The case itself is cast with four slotted lugs which can be slipped over the heads of lag screws for suspension on buildings or other similar surfaces. In addition to this each transformer is supplied with a pair of hanger irons, as shown in the illustration, with studs designed to enter the slots on the lugs of the case, the irons being bent at their upper ends, as shown, in order to conveniently hang over a cross arm. The outward bending is designed to allow the two hangers to be placed respectively on opposite sides of the pole so that the transformer may hang immediately below the center of the cross arm and against the pole. The Pittsburgh Transformer Company announces that it is meeting with largely increased sales and has enlarged its manufacturing facilities in order to

Digitized by Google

supply this increased demand. Besides its line of standard transformers it is now building a number of remarkably high voltage transformers with a ratio of 40,000 to 5000 volts. These are for use in a western installation.

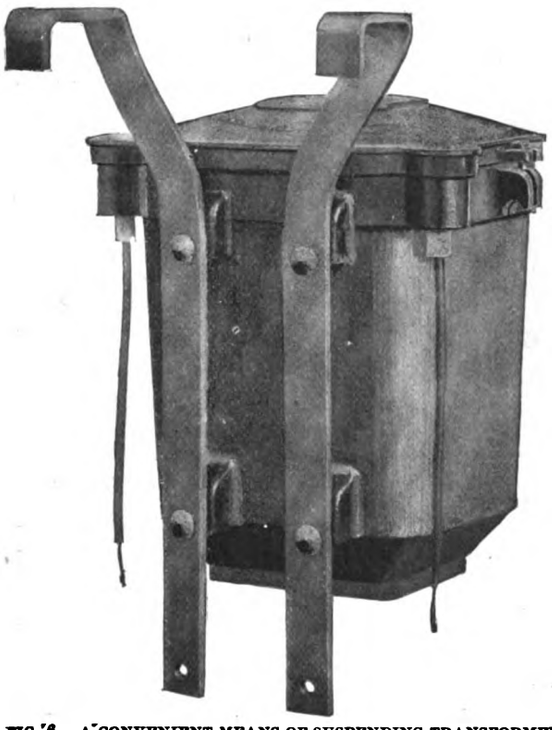

FIG. 6.—A CONVENIENT MEANS OF SUSPENDING TRANSFORMERS.

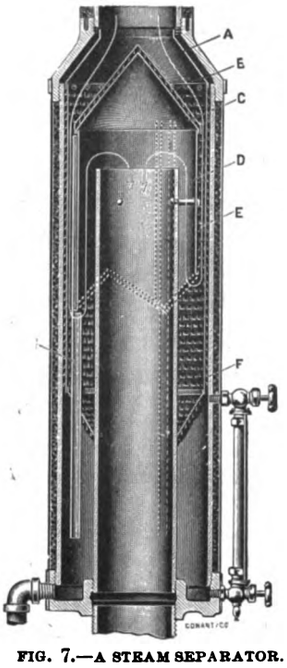

FIG. 7.—A STEAM SEPARATOR.

### THE DIRECT STEAM SEPARATOR.

The operation of the separator, shown in Fig. 7, is as follows:

The accumulated moisture around the walls of the steam pipe is caught by the upper edge of cone A and carried down back of the lining to the water chamber. The current of steam entering the separator impinges upon the conical surface composed of solid plate C, covered with sieve B, through which water may freely pass, but from which it cannot readily escape. Passing through the sieve and depositing on the solid surface of the cone, C, this water is carried by conductors to the water chamber. By means of the cone the column of steam is changed to an annular ring, which is comparatively thin, even while the full area of the pipe is maintained. The steam upon the outside of this ring comes in contact with the lining of the shell, which has a sieve of the same character, as at B, and which catches and entrains any water which may be contained in that portion of the current. There is also provided a lip at lower edge of the inverted cup, which leads all the water that may adhere to its surface down to the conductors to the water chamber. The current of steam passes through the passages indicated by white lines, and is subjected to a whip-snapping action which will throw off any moisture which has not been caught by the surface over which it has passed.

The diaphragm, F, prevents the steam from picking any water out of the water chamber. The plate, C, is a substantial gray iron casting resting securely upon three castings hooked over the top of and securely riveted to the inner pipe. The trapping sheets are of heavy gauge cold rolled copper and the construction is in every way as secure as the best judgment of the inventor, backed by five years' experience in this business, can make it. Every machine is tested at 250 lbs. pressure before shipment and covered with the best non-conductor and a polished jacket, making it in appearance suitable for attachment to any of the highly finished engine cylinders.

These separators are made by the Direct Separator Company, Syracuse, N. Y. Professor Sweet is the inventor of the separator.

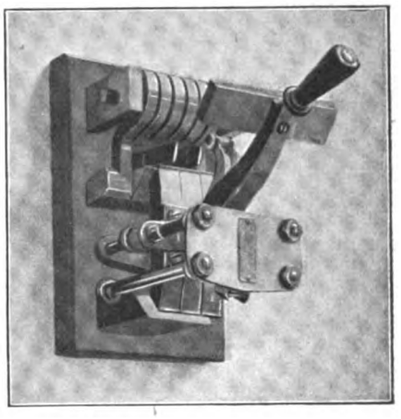

FIG. 8.—AN UNDERLOAD CIRCUIT BREAKER.

### A NEW CIRCUIT BREAKER.

The contact between the heavy blades and clips of very large switches or circuit breakers is intimate over the whole surface and of low resistance only when the parts are ground and accurate in

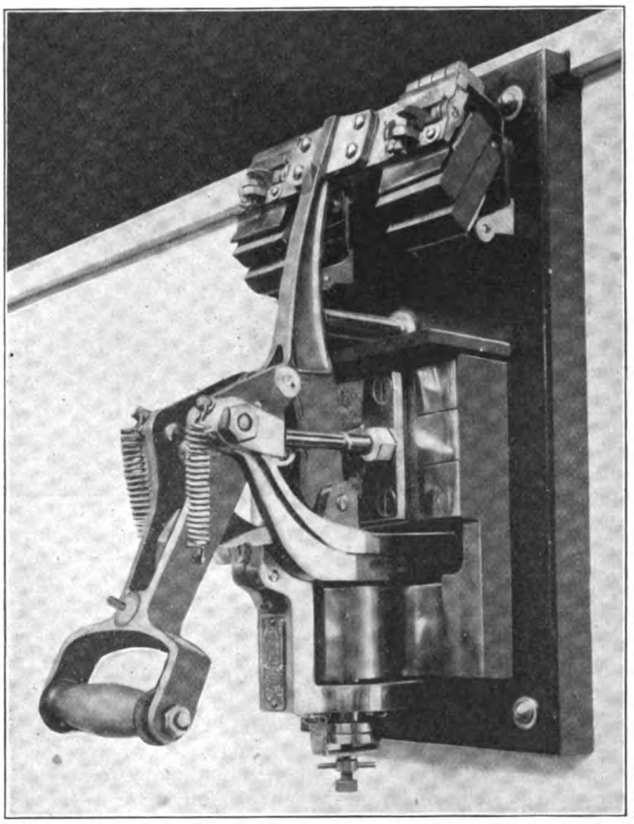

FIG. 9.—THE I. T. E. CIRCUIT BREAKER, WITH LAMINATED LEAF CONTACTS.

Digitized by Google

alignment and forced together under considerable pressure. For the transmission across the contact of the very large currents of large installations this necessitates parts of considerable weight, and consequent cost at the present price of copper, in addition to which the rubbing pressure upon the moving parts makes them difficult to manipulate. The Cutter Company, Philadelphia, Pa., has brought out a new form of the I. T. E. circuit breaker, utilizing as its main or primary contacts the ends of thin laminated leaves instead of the blades and clips used up to the present. The instrument embodies several other improvements in circuit breaker construction which are shown in Fig. 9, reproduced from a photograph of a 1500-ampere breaker designed for railway voltages, and exhibited at the New York Electrical Show.

The main contact consists of a lot of fine springy leaves extending across the body of the instrument and forced back by a toggle joint, connected to the handle, giving a pressure of a good many hundred pounds with considerably less force than that required to manipulate the older types of breakers. The leaves are slightly curved at their ends so that as they are forced between the wedge-shaped contact blocks they will take a true bearing. The secondary break is at the top of the instrument, removing from the other parts any arcs that may tend to form. The carbons are on the end of a long arm which is forced into position by means of the wedging action of the handle and thrown out very quickly when the trigger releases it. As the delicate leaves of the primary break are more likely to injury in case the secondary does not make a good contact and the arc is thereby transferred to the primary, there is a double path through the secondary contacts at the top of the instrument. Just above the carbons will be noticed a copper contact which acts as a low-resistance shunt to the primary leaves below, opening after they do, but before the carbons separate. There are thus in this breaker three paths for the current opening in the following order: First carbon, second copper, and third, main copper leaves.

Fig. 8 shows a smaller breaker designed for underload release for storage battery or similar work. Here the releasing device is simply an armature across the poles of the magnet at the top of the instrument. A little secondary break is provided in the form of a short rod entering between two clips in the middle of the instrument. The primary leaves in this case run vertically and the arrangement of the wedge-shaped contacts is clearly shown as the instrument is illustrated in the open position.

### A CONVENIENT BORING TOOL.

For boring holes in joists or under partitions from floor pockets or similar positions difficult of access, the Anthony joist machine or universal boring tool shown in Fig. 10 is particularly convenient. The machine works without a ratchet, giving the bit a continuous rotation. There is a long range for adjustment from the guide to the bit. The main handle is also adjustable and the machine can easily be taken to pieces for packing in a grip or

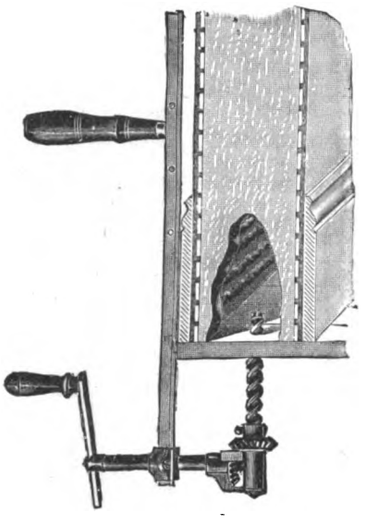

FIG. 10.—A CONVENIENT BORING TOOL.

tool box. It is made by the American Electric Company, Detroit, Mich.

### A HIGH TENSION GENERATOR.

The arrangement of the parts of rotating field machines so that both the field and armature coils shall be accessible for replacement or rewinding is necessarily

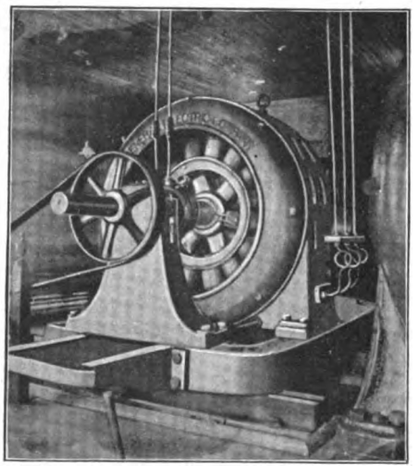

FIG. 11.—A HIGH TENSION REVOLVING FIELD DYNAMO.

somewhat different from that of machines with rotating armatures. The external stator, if it carries a multiphase winding cannot be split so that the top can be removed or either half moved out laterally from the shaft. The machine must then be made so that either the rotor can be moved out axially from within the stator or the stator slid endwise to clear the rotor. Fig. 11 shows the arrangement adopted by the General Electric Company in machines of this type. It will be seen that the base carries a bracketed extension and the shaft is extended considerably beyond the exciter pulley. Close examination will also show, although it does not appear very clearly in the illustration, a strut from the external stationary armature to the pedestal in the foreground. A number of holes will also be seen in the casting which forms the base plate of the machine. The general purpose of these devices is to allow the external armature and the one pedestal in the foreground to be moved along the shaft such a distance that the coils will completely clear the field poles and allow the ready repair of either. This is accomplished as follows:

The exciter pulley is removed, as are the bolts holding the pedestal and the armature shell to the base plate; a small jack-screw is then inserted in one of the holes in the base plate behind the armature shell casting, on each side of the machine, and screwed up to push the parts forward along in the direction of the shaft, the pedestal moving out on to the bracket shown. By this means a coil may be replaced or a new field pole put in in a short time without the use of any crane or tackle and without any serious dismantling of the machine. The illustration shown is that of a 250 kw. 10,000-volt generator, supplying three-phase power to a transmission line running to Portland, Maine.

### AN IMPROVED LAMP SOCKET.

The new regulations of the National Electrical Code specify several detail changes of lamp sockets that make new models necessary. Among these are the

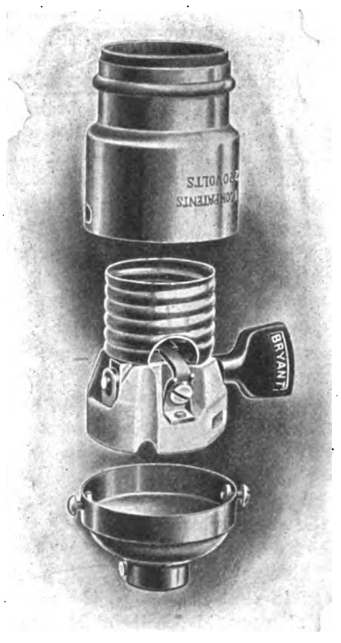

FIG. 12.—A LAMP SOCKET COMPLYING WITH THE NEW UNDERWRITER'S REGULATIONS.

requirements that the shells must be lined with an insulating material and that the socket must be able to safely stand any pressure up to 250 volts. The Bryant Electric Company, Bridgeport, Conn., has modified its standard Edison socket to

Digitized by Google

meet these regulations, the appearance of the new socket being shown in Fig. 12. The arrangement of the parts is clearly shown in the illustration. This socket will be in the hands of the principal jobbers by the date on which the requirement goes into effect, viz., July 1.

### AN AUTOMATIC CIRCUIT BREAKER.

The increasing popularity of the circuit breaker in place of the fuse has brought on the market several new types and makes, one of which is made by the Fisher Electrical Manufacturing Company, Detroit, Mich., and shown in Fig. 14. As will be seen, the moving parts of this instrument slide vertically instead of swinging from the switchboard, giving more rigid alignment than can be obtained by hinges. The handle for restoring the breaker is so arranged as to give great leverage and consequent ease of manipulation. The secondary or carbon breaks are placed outside the main contacts, keeping the arcs well away from each other to avoid any danger of jumping across. There are also no metallic parts between the two poles of the instrument to which the current can jump.

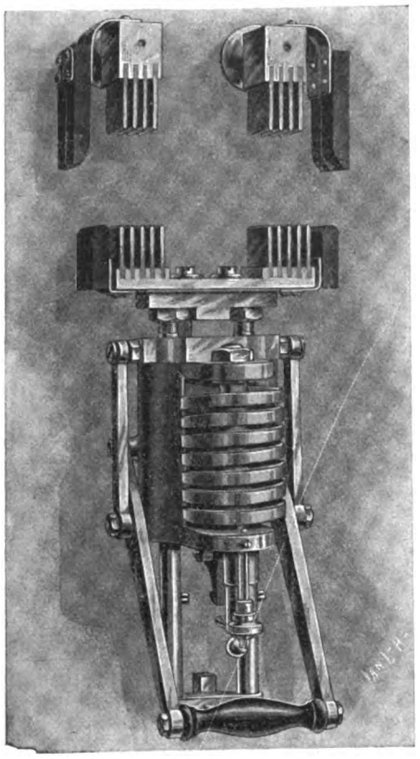

FIG. 14.—AN AUTOMATIC CIRCUIT BREAKER.

### THE AULTMAN CHAINS FOR POWER TRANSMISSION AND ELEVATING AND CONVEYING PURPOSES.

The Aultman Comapny, Canton, Ohio, has recently placed on the market a complete and novel line of chains for the transmission of power and elevating and conveying service.

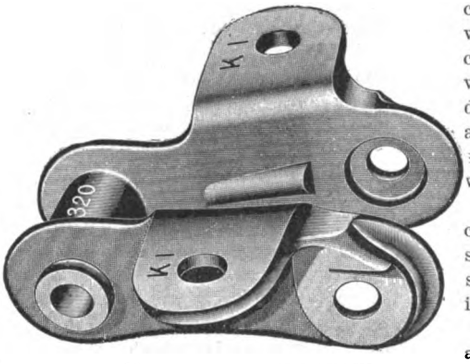

FIG. 16.—A PINTLE TYPE CHAIN.

The salient features of the chain shown in Fig. 15 are strength, durability and moderate first cost. The side bars are interlocked with each other. The renewable wearing band or sleeve is socketed into the inner face of the side bar, but is entirely free to turn in the socket and around the bolt. The working strain is borne largely by the wearing bands or sleeves instead of the bolts. The bolts are secured by a perfect nut lock and need not be riveted unless so desired.

FIG. 17.—A SPROCKET WHEEL FOR CHAIN DRIVES.

The links are thus well protected from dust and grit, but can be readily separated and uncoupled. The uncoupling can be done with the chain as tight on the wheels as it should ever run. For work requiring great strength the chain can be worked in double strand.

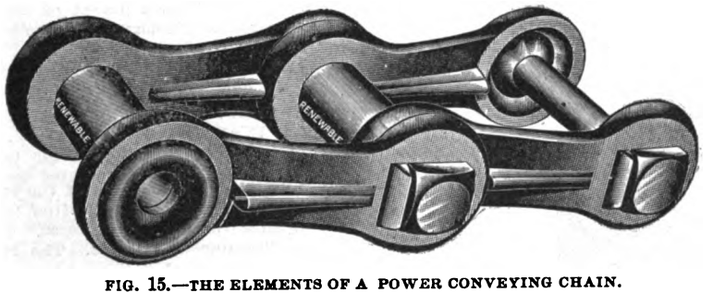

FIG. 15.—THE ELEMENTS OF A POWER CONVEYING CHAIN.

Another case of interlocking chain belt is the pintle type, as illustrated by Fig. 16. The construction of this chain gives great wearing surface and strength with minimum weight. The wear is entirely on the cross bar and interlocking socket joints, which are practically dust-proof. The chain articulates freely and easily, and is well adapted for any purpose common to detachable chain belt. The construction allows the chain to be used with either side to the sprocket, or one side can be worn down and the chain reversed.

Sprocket wheels for the foregoing chains are furnished with chilled teeth or semi-steel mixture where extra severe service is to be met, or the usual grey iron wheels can be had.

Still another departure in chain design and construction is shown in the scraper and conveyor chains illustrated in Fig. 18.

### TESTS OF A STEAM SEPARATOR.

In a paper presented before the last meeting of the American Society of Mechanical Engineers, Mr. F. L. Emory described some tests of the performance of an Austin steam separator of the baffle-plate pattern, designed to serve as a live steam separator, as an exhaust steam separator or trap, or as an oil extractor. The method of testing consisted in brief of a determination of the quality or wetness of the steam before and after it passed through the separator. The tests were made at various pressures and velocities and the quality of the entering steam was changed by means of a water jacket by which the steam could be partially condensed and the conditions thereby made peculiarly severe. The quality or wetness of the steam was measured by means of separating calorimeters, checked under those conditions where it was possible, by means of throttling calorimeters, the

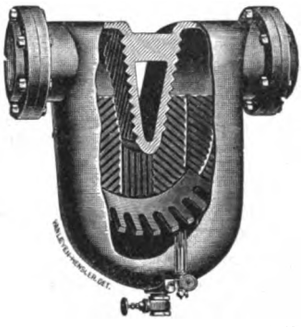

FIG. 19.—A STEAM SEPARATOR AND OIL EXTRACTOR.

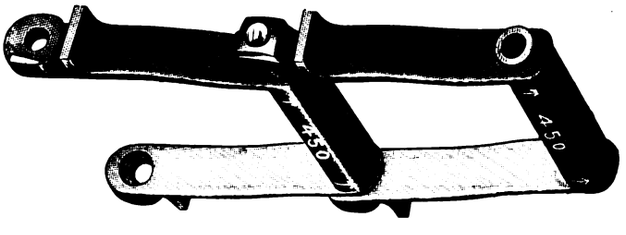

FIG. 18.—A CHAIN FOR SCRAPERS AND CONVEYORS.

Digitized by Google

steam being afterwards condensed and weighed, and the drip of the separator being collected and weighed to give a check upon the other factors. The separator used was of the horizontal type, as made by the Austin Separator Company, Detroit, Michigan, and is shown in Fig. 19.

The results of the test were given by Mr. Emory in the form of tables which are rather too long for reproduction here, the conclusions which he drew being as follows: The separator will, if kept well drained, deliver a steam dry within 3 per cent., i. e., of 97 per cent. dryness, no matter what the quality of the entering steam may be, and shows little separating qualities in steam of a dryer quality. There seems to be little difference between its action on live steam of high pressure and exhaust steam of low pressure. Even with pressures as low as 3 pounds above atmosphere, corresponding to ordinary engine exhaust, the separator gave practically the same results, i. e., it allowed to pass through in liquid form only 3 per cent. of the total weight of fluid. The same instrument was tested as an oil extractor by pumping into the entering steam "vacuum" cylinder oil at about the rate of ordinary working conditions in engine lubrication. The oil coming away with the water in the drip from the separator was skimmed and dried; corrections were made for the water added to it, its weight was compared with that introduced, and it was found that about 50 per cent. of the oil was recovered.

### THE NOARK ENCLOSED FUSE.

The lack of safety, accuracy and reliability of action inherent in the ordinary bare wire of a lead alloy, commonly used as a protecting device for electrical circuits, has led to its general condemnation and to the wide use of mechanical circuit opening devices. On the other hand, the cheapness, simplicity and peculiar advantage of a time interval obtained by the thermal action of a fuse have caused its retention in spite of the disadvantages named.

The enclosed fuse has during the last few years been gradually developed to a high state of perfection by which these disadvantages are done away with. In the type shown in Fig. 20, which was designed by Mr. Joseph Sachs and is being introduced to the market by the H. W. Johns Manufacturing Company, New York City, objections which applied to earlier types of enclosed fuses have been overcome. The requirements which this fuse has been designed to meet are as follows:

It must operate with any excess of current above its rating in case this current continues for a time interval inversely dependent upon the amount of the excess. It must open the circuit without arc, flash or bursting and yet positively leave an indication that it is opened. It must be unaffected by time or atmospheric conditions, and of low cost, simple in construction and easy of manipulation.

Structurally the fuse consists of a fibre tube capped at each end with a brass ferrule and filled around the interior fuse wire with a material which absorbs the melted metal when the fuse blows and prevents the formation of a conducting vapor. It is claimed that the action is such that the circuit is not broken instantaneously, which is liable to result disastrously in case of a great amount of self-induction, but the resistance rises to infinity quickly and uniformly as the metal of the wire combines with the surrounding material.

One of the most striking features of this instrument is the simple indicating device which overcomes a great objection to previous types of fuses which give no indication whether the circuit is open or closed. This consists of a fine wire of highly resisting alloy, run outside of the tube between the brass ferrules. When the fuse within blows, the whole current is thrown upon this fine wire which is instantly vaporized, leaving upon the casing a well defined black line. The structural details of the fuses have been well worked out for the various requirements and a complete line of fittings for them has been designed.

FIG. 20.—AN INDICATING ENCLOSED FUSE.

## NEW BOOKS.

Premiers Principes d'Électricité Industrielle. By Paul Janet. Third edition revised. Paris: Libraire Gauthier-Villars. 273 pages, illustrated. Price, 6 francs.

The third edition of this well-known work does not differ materially from previous editions, but contains numerous additions to branches of the science that have been subject to notable developments recently. Among the subjects thus amplified are induction motors and polyphase dynamos and storage batteries, to which recently published information on the subject of rapid charging and discharging and charging at constant potential has been added.

The Commercial and Business Aspects of Municipal Electricity Supply. By Alfred H. Gibbings. Bradford, England. Published by the author, 270 pages, illustrated. Price 15s.

Municipal electric lighting is taking a much firmer hold in England than it has as yet in this country, and this work by the electrical engineer of the city of Bradford gives a very good idea of the present status of this branch of electrical engineering in England. The work was compiled mainly for the use of municipal engineers and committees, the object aimed at being the elucidation of the commercial aspects of electricity supply in such a manner as to present to the ordinary business man the peculiar conditions which differentiate this line of business from the sale of most marketable commodities. Owing to the scarcity of literature on this particular branch of the subject—most works being devoted largely to the engineering aspects—the work should prove particularly valuable to English municipal engineers and of no little value to municipal authorities or engineers in this country contemplating the establishing of municipal plants and desirous of thoroughly informing themselves on all branches of the subject. Some of the subjects most thoroughly treated are: The position of the electricity department in relation to other municipal departments, how to charge for electrical energy, the renting of motors, arc lamps, etc., the prepayment or penny-in-the-slot meters, free wiring and free lamp renewals, the fitting up of a show room with fixtures, etc.

## LEGAL NOTES.

THE CARTY BRIDGING BELL DECISION.—The United States Circuit Court of Appeals handed down a final decision at Philadelphia on June 8th in the case of the Millheim Electric Telephone Company vs. the Western Electric Company. The opinion was on an appeal from a previous devision upholding the well-known patent of 1891 to J. J. Carty for multiple party line combination of telephone apparatus. The final decision upheld the decree of the Circuit Court, holding that the patent is valid and infringed.

THE LITIGATION BETWEEN THE HANCOCK INSPIRATOR COMPANY, of Boston, and the Penberthy Injector Company, of Detroit, has been terminated by the Penberthy Company purchasing of the Hancock Inspirator Company the Loftus "ring valve" injector patent, No. 300,092, upon which the litigation was based. The Hancock Company reserved a license to manufacture injectors under this patent not intended for the farm engine trade. The American Injector Company has for several years had a license under this patent, but desiring an interest in the patent and the dismissal of a suit against it by the Penberthy Injector Company on the Borland patent, it has purchased a one-third interest. It and the Penberthy Injector Company are now the sole owners of the Loftus patent above referred to.

Digitized by Google

THE COLLIERY ENGINEER COMPANY, proprietor of the International Correspondence Schools, Scranton, Pa., has brought suit against the United Correspondence Schools, New York City, and the American School of Correspondence, Boston, Mass., for infringement of its copyrights. The preliminary injuction was denied by Judge Lacombe, of the United States Circuit Court, on the ground that it would work irreparable damage to the defendants, and it was thought best to relegate the action to final hearing. The International Correspondence Schools announce that it is their purpose to proceed with all possible speed in both suits to a final determination.

## PERSONALS.

MR. SAMUEL INSULL, president of the Chicago Edison Company, was quietly married in New York City on May 23 to Miss Gladys Wallis, the well-known actress.

MR. A. A. ZIEGLER announces that he has resigned his position as President and General Superintendent of the Ziegler Electric Company, Boston, Mass. Mr. Ziegler states also that he expects soon to enter again into the same line of business.

MR. FRANK G. BOLLES has resigned his position as advertising designer and writer of special literature for the Westinghouse Electric and Manufacturing Company, and has accepted the management of the advertising department of the Bullock Electric Manufacturing Company, of Cincinnati.

PROF. WILLIAM S. ALDRICH, heretofore of the West Virginia University, who is well known to readers of the American Electrician through his contributions to its columns, has just been appointed to the chair of electrical engineering of the University of Illinois, Champaign, Ill.

MR. F. S. PEARSON, chief engineer of the Metropolitan Street Railway Company, New York City, and famous for his work in open conduit systems, sailed on June 5th for San Paulo, Brazil, to look at the development of a street railway and lighting system to be installed by the Pearson-Mackenzie Syndicate. A water power will be utilized and a small steam plant will be temporarily installed for immediate service.

MR. JOHN S. STONE, formerly of the engineering staff of the American Bell Telephone Company, has opened an office in the Phillips Building, Boston, as an electrical engineer and expert. Mr. Stone's work on the modern development of American Bell apparatus, chiefly the relay and visual signal systems, has been both extensive and valuable, as the records of the patent office for the last few years show, so that his services will undoubtedly prove to be of value to any one needing expert work in telephony.

MR. W. F. KELLY, formerly with the Columbus Street Railway Company, Columbus, Ohio, has resigned from his position there to become the railway manager of the Safety Third Rail Electric Company, New York City. It is the purpose of the banker, Mr. Emerson McMillin, who is heavily interested in the Safety Third Rail property, to actively push its interests, and his choice of Mr. Kelly, who has seen considerable service in the McMillin property at Columbus, speaks well for the latter's managerial ability.

## TRADE PUBLICATIONS.

THE H. C. ROBERTS ELECTRIC SUPPLY COMPANY, Philadelphia, Pa., has circulated a new catalogue of tools and appliances for electric light, railway, telegraph and telephone construction.

THE MASON REGULATOR COMPANY, Boston, Mass, has published a catalogue descriptive of the Mason speed governor for steam pumps. The catalogue is a most complete one, showing and describing every detail of the internal construction of the governor, so that its operation can be clearly understood.

THE UNITED ELECTRIC HEATING COMPANY, Detroit, Mich., has issued a new illustrated price list describing several new additions to its list of manufactures, among them a new portable stove, a curling iron heater and a new soldering iron made of aluminum. The company reports the demand for its goods greater than ever before.

YE DECLARATION OF INDEPENDENCE is something that every one has heard about but which it is hard to lay hands on when the occasion arises to refer to it, as it does about this time of the year. The John A. Roebling's Sons Company, New York City, has published a neat pamphlet showing a fac-simile of the original document as well as a copy in type, which can be had on application to the company.

THE DETROIT LUBRICATOR COMPANY, Detroit, Mich., has just gotten out a new line of glass body oil cups and glass body oil pumps. The oilers, while simple in design, are equipped with all the latest improvements, including the set feed and stop feed features, and are well and strongly made, with cast tops and bottoms. The company has also issued some printed matter descriptive of these devices.

A. L. IDE & SONS, Springfield, Illinois, have issued a new catalogue of the Ideal engines. Besides describing and illustrating with remarkable clearness all the details of the engine, the catalogue also shows a number of special equipments and devices such as the Ideal throttle valve, steam separator, reducing motion, power transmitter, belt tightener, etc.

THREE HANDY POCKET CATALOGUES, or rather descriptive pamphlets, are those recently published by the Westinghouse Electric & Manufacturing Company on the Wurts non-arcing lighting current and the Westinghouse alternating current and direct current fan motors for 1899. The first of these lists the various styles of Wurts arresters for stations and line use on either direct or alternating currents with the choke coils for use therewith. The others describe and illustrate the fan motors previously described in these columns.

SCHEEFFER WATTMETERS.—The Diamond Meter Company, Peoria, Ill., has published a new catalogue of the Scheeffer recording wattmeters for alternating currents. The new catalogue is of particular value to central station men, whether they use Scheeffer meters or not, owing to its complete detailed instructions for the calibraton of meters. The catalogue also lists convenient pieces of apparatus for use in testing meters, among them a rheostat to give graduations of the load between lamps, and a convenient leveling table for mounting the meters.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, New York, has a classification of its rheostats which renders it a simple matter to determine just what rheostat is wanted for any given service. The number of ohms of resistance of each instrument is given as well as the maximum number of amperes which it will carry continuously with the entire rheostat in circuit and the maximum number of amperes which it will carry continuously with only one step or section in the circuit. A catalogue recently issued gives the prices of the company's complete line of seven styles based on these classifications.

RURAL SUMMER HOMES is the title of an illustrated guide to the summer homes adjacent to New York on the Erie Railroad and its branches. The volume is as attractive in appearance as a high-class illustrated magazine and gives complete detailed information on all points which a prospective summer boarder could wish to learn about. Besides the general description of the country, which is attractively written, the guide contains lists of the hotels and boarding houses, giving rates, capacity for guests, distance from stations, means of conveyance and other details. The work also contains many illustrations of these places of temporary abode as well as a topographical map of the lines.

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has published a small pamphlet which central station men would do well to obtain in quantities and distribute to their patrons. The pamphlet is entitled "Use Electricity in Your Home and Business," and describes and illustrates the various devices by which alternating current can be made use of, especially in the home. Among these devices are desk and ceiling fan motors, a sewing machine motor, motors for small power users and for small factories, special types for church organs and blacksmiths' blowers. A line of electrical heating apparatus is also described, as well as enclosed arc lamps, a watch demagnetizer, surgical transformer for cautery, and a phonograph motor.

## BUSINESS NEWS.

THE HARDY LAMP COMPANY, Pittsfield, Mass., is actively pushing arrangements for doubling the capacity of its plant in anticipation of a very busy fall season.

GEORGE WILLIAM HOFFMAN, Indianapolis, Ind., states that he has just shipped to Canada a large order of his U. S. metal polish.

THE ELECTRIC STORAGE BATTERY COMPANY has moved its general offices in Philadelphia to the new factory building, 19th Street and Allegheny Avenue.

THE FALK COMPANY BURNED OUT.—The entire establishment of the Falk Company, at Milwaukee, Wis., including shops and offices, was destroyed by fire on June 13th.

THE W. H. ELLIOTT ELECTRIC COMPANY, Cleveland, O., has recently removed its factory to 1076 West Hamilton Street, where it will have exceptional facilities for its class of work.

THE HOLTZER-CABOT ELECTRIC COMPANY, Boston, Mass., is making an addition to its factory, necessitated by its largely increased business. The new building is 60 x 40 ft. in size and three stories high and will contain about 10,000 sq. ft. of floor space.

THE ZECO ENCLOSED DIRECT CURRENT ARC LAMPS have evidently found favor with central station managers, as is shown by that best expression of appreciation, repeat orders, a large number of which have reached the Central Electric Company, Chicago, Ill., during the last few months.

THE VAN DORN COUPLERS, made by the W. T. Van Dorn Company of Chicago, Illinois, described in the last issue of the American Electrician, have been adopted as the standard on the elevated roads of Chicago and of Brooklyn, and are in general use on some 200 surface roads in this country.

THE ALLEN-HUSSEY COMPANY, manufacturer of interior telephones, having principal offices in New York and Chicago, reports placing new agencies in several of the larger cities during the past months. The company has issued a sheet of diagrams of wiring, illustrating the many uses of its specialty, interior telephones.

A GENERAL ELECTRIC DIVIDEND.—At a meeting of the directors of the General Electric Company, held on May 22, a dividend of one and one-half per cent. was declared upon the reorganized common stock, payable July 15. The directors expect to declare quarterly dividends at this rate here-

Digitized by Google

after. Books for the dividend close June 30 and reopen July 17.

THE AMERICAN WOVEN WIRE BRUSH COMPANY, Peabody, Mass., has been under new and progressive management since March of this year, and its business has greatly improved, owing to the fact that it is making better brushes and more prompt deliveries. The company announces that it has facilities for filling orders of any probable size for these goods from jobbers and users.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., have had constructed two special combined sleeping and exhibit cars for the railway department of the schools. These will be sent around the country to give an impressive exhibit of the company's work. One of them has already gone to the Railway Master Car Builders' Convention at Old Point Comfort, Virginia.

THE ENTERPRISE ELECTRICAL COMPANY, Cleveland, O., has completed its contract for the equipment of the Hollenden Hotel of that city. The installation includes a 400 number Partrick, Carter & Wilkins patent needle annunciator, together with telephone room sets and fire alarm attachments. The Partrick, Carter & Wilkins annunciator system is very popular among hotel proprietors, some of the largest and finest hotels in the United States being equipped with that apparatus.

THE HOPPES MANUFACTURING COMPANY, Springfield, Ohio, reports cases of that best of recommendations, a repeat order, from many well-known firms, among them the following: The Deering Harvester Company, two 1250 h. p. purifiers; The Louisville Railway Company, three 625 h. p. purifiers; the Danville Gas, Electric Light and Street Railway Company, 1000 h. p. purifier; the Jeffrey Manufacturing Company, 500 h. p. purifier and 500 h. p. heater.

THE INSTITUTE FOR HOME STUDY OF ENGINEERING, of Cleveland, has recently been incorporated with the United Correspondence Schools, of New York. The consolidation will result in great benefit to the students of the Cleveland Institute. All contracts with students will be carried out and they will have the advantages resulting from the large capital, increased facilities and the improved and perfected courses of the United Correspondence Schools.

THE PELTON ENGINEERING COMPANY, Cleveland, O., has recently moved to Hamilton Avenue, near Belden, where it has a space nearly three times as large as their old quarters. Mr. W. H. Pelton, the manager of this concern, recently stated that as far as business was concerned there was no summer season with his company, as there was no diminution of orders, and that the company had already an amount of business booked that would carry it well into the fall.

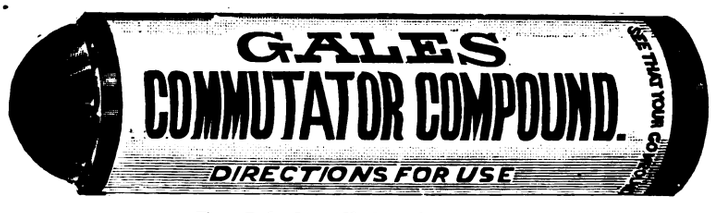
THE AMERICAN ENDOSCOPIC COMPANY, Providence, R. I., has put on the market a convenient electric hand light called the "Little Rhody." This consists of four cells of dry battery mounted in a case with a handle, switch, lamp socket and reflector. The apparatus complete weighs just 18 oz. and measures 9 in. in length, including the lamp and reflector, by 1¼ in. in width and 2½ in. in heighth. The sets are made in three different styles of finish. The batteries will run 10 consecutive hours and a new battery can be put in at a small cost.

THE SLOW DEPRECIATION OF STURTERVANT FANS.—The wonderful endurance of a well designed and thoroughly constructed fan blower is emphatically evidenced by a recent statement of The William Kennedy & Sons, Ltd., Owen Sound, Can., to this effect: "We have two Sturtevant pressure blowers in use, one of which has run over 32 years steadily, and often 24 hours per day, and is apparently as good as when installed, although no one has as yet seen the inside of it. The other has been used for foundry purposes, and has been in use for about 30 years or so."

THE DIRECT SEPARATOR COMPANY, Syracuse, N. Y., reports a large number of sales during May and June, one party having sent a duplicate order for eighteen steam separators; another the tenth order for four large ones, making thirty-nine separators in the service of this one user. Another company sent in its forty-ninth order, making one hundred separators in its use. These duplicate orders, of which the makers have received so many, are increasing all along the line. During the above two months to June 12th, twenty-two such orders, covering fifty-eight machines, were received.

THE HARRISON SAFETY BOILER WORKS, Philadelphia, announces a large list of recent sales of Cochrane feed water heaters and Cochrane separators. Among the largest orders for the former were 10,000 h. p. for the Ohio Steel Company, 6000 h. p. for the Alabama Steel and Wire Company and 1000 h. p. for the Gabriel Electric Company. Of separators—three 16 in. and one 10 in. were sold to the Carnegie Steel Company, one 14 in. to the Gisholt Machine Company, one 16 in. to the Alcania Electric Company, a large order of various sizes to Laughlin & Company, Ltd., besides many of the smaller sizes.

MANUFACTURERS OF ELECTRIC AUTOMOBILES would do well to correspond with the Mica Insulator Company, New York and Chicago, in reference to "Micanite" insulation. This concern is especially equipped for the manufacture of commutator rings and segments for motors of this class of work. The "Empire" and "M. I. C. Compound" cloths and papers are being used quite extensively by manufacturers of motors for electric vehicles. The company offers to send to any manufacturer of such motors a set of rings and segments for trial, free, together with samples of "Micanite" and "Empire" insulating cloth and paper.



THE MURPHY AUTOMATIC SMOKELESS FURNACES, installed in the National Carbon Company's works, Cleveland, O., have now been in operation several months, and the superintendent says: "We are saving at the rate of twenty dollars per day (24 hours) now as compared with cost of our steam when using a hand stoked furnace." The equipment of the entire plant of 1600 h. p. cost about seven thousand dollars. The Murphy Automatic Smokeless Furnaces, installed in the Raritan Copper Company's new works at Perth Amboy, N. J., have very complete systems of coal and ash handling, and all are giving excellent satisfaction. The coal used is bituminous "run of mine" from the "Beach Creek," Pa., district, yet the chimney is practically as clean as where anthracite is used.

THE WESTERN ELECTRIC COMPANY, in addition to its complete line of fan motors, is also building a complete line of power motors from 1/36 horse power up to 15 horse power in the encased and semi-encased open type style, and larger sizes in the open type style. The company has recently constructed an extensive arc light switchboard for the Ottawa Electric Company, Ottawa, Ontario. The board is built of marble panels, and mounted in an iron frame. It is designed for 24 circuits and 24 arc dynamos. The Western Electric Company is installing in Hillman's Department Store, Chicago, one 60 kw. and one 100 kw. 110 volt generators, and a 2-panel 5-circuit switchboard. 112 Petite arc lamps and 1500 incandescent lamps will be used for the interior illumination of the store.

A NEW BATTERY MANUFACTURING PLANT IN ST. LOUIS.—The Phoenix Carbon Manufacturing Company, St. Louis, Mo., has sold its electric light carbon and motor brush departments to the National Carbon Company, of New Jersey. Immediately after this transaction was completed the Phoenix Battery Manufacturing Company was organized, with a full paid-up capital of $250,000. This company has just purchased a tract of land, of about eight acres, located in the southwestern part of St. Louis, adjoining the line of the Missouri Pacific Railway. It will at once begin the construction and equipment of what it claims will be the largest battery manufacturing plant in the world. Among the gentlemen interested in the enterprise is Col. S. G. Booker, who has for many years been prominently identified with battery-carbon manufacturing interests.

ENGLISH PRESSES DRIVEN BY AMERICAN MOTORS.—The Bullock Electric Manufacturing Company, Cincinnati, will ship to England this month one 25-h. p. generator and two 30-h. p., one 40-h. p. and two 30-h. p. printing press equipments for the Manchester "Sporting Chronicle." One 28-h. p. type 0 printing press motor, with controller, will go to Cassell & Co., London, the

# A COMMUTATOR NECESSITY.

largest publishing house in England. A slow-speed motor for direct connection to a lithograph press, with controller, will be forwarded to the Belfast "Evening News." which will also take a 30-h. p. printing press equipment, with teasers and controller. Two 30-h. p. motors for large presses, with teasers and controllers, will be dispatched to the London "Daily News." These shipments will be the most important that have ever been made from this country to newspaper establishments on the other side.

GATES & RANDOLPH have taken offices and warerooms at 13 and 15 Monadnock Building, on the ground floor, Chicago, formerly occupied by Sargent & Lundy. They are handling the apparatus of the Triumph Electric Company, Cincinnati, Ohio, for direct current work; the Warren Electric Manufacturing Company, Sandusky, O., for alternating work; the Empire Electrical Instrument Company, New York, for portable switchboard alternating and direct current instruments; F. A. La Roche & Co., New York, for switchboards, circuit breakers and switches; Sterling Arc Lamp Company, New York, inclosed arc lamps for all circuits. It is the purpose of Gates & Randolph to operate a miniature electric lighting plant in their new warerooms, using a Triumph motor, running a Warren alternator through a La Roche switchboard, with Empire instruments and transformers, etc., with arc and incandescent lamps and motors running from the same circuit.

THE COLUMBIA ELECTRICAL SUPPLY COMPANY opened its new headquarters at 93 Liberty Street, New York City, on June 21st. The establishment at 329 Fourth Avenue, New York, will hereafter be run as a branch store, as will that in Albany, N. Y. The new headquarters are admirably located in the center o fthe engineering office district in New York City and consist of three floors, the ground floor, basement and sub-basement each about 100 ft. by 25 ft. in size. The lower floors are admirably arranged with bins and shelves for the complete stock of lighting and telephone supplies and electrical house goods which the company will carry, one ingenious detail being the inclined racks for the storage of moulding. The officers of the company are: T. M. R. Meikleham, President; H. P. Douglas, Vice-President; J. S. Douglas, Treasurer; W. B. Dinsmore, Jr., Secretary. Two other men well known in electrical supply circles and now connected with the sales department of this company are Messrs. Geo. Stanmore and J. C. Moulton.

THE MONTAUK AUTOMATIC THERMOSTATIC FIRE DETECTIVE CABLE covers a field which heretofore, electrically speaking, has but tentatively been occupied. Messrs. Stanley & Patterson, New York, among other installations, have recently placed an equipment in the home of Mr. Joseph Pulitzer, of the New York "World"; the firm of Doscher & Hartwell, electrical contractors, among other installations, has recently equipped the winter residence of Mr. George Taylor, in New York City, and also his summer residence on Long Island; the Jenney Construction Company, New York City, is doing a prosperous business in the installation of this cable, and among the many installations made by it may be mentioned the winter and summer residences of Mr. A. A. Cowles, President of the Ansonia Brass and Copper Company. Among the various installations made by the Gamewell Auxiliary Fire Alarm Company, the Dundee Chemical Works, Passaic, N. J., and the Jessup & Moore Paper Mills, Wilmington, Del., may be cited.

A UNIQUE FEATURE of the city of Detroit, the so-called City of Conventions, is the novel welcome extended by the City Council to the various conventions which gather there during the summer. Across the entire face of the city hall, which faces the large square known as Campau Place, the center of the city, is a large skeleton frame work on which is erected a large electrical sign. This sign is changed from day to day or as occasion arises by the visits of various conventions. The signs are very handsome ones and the entire work is in the hands of the Michigan Electric Company, which has contracted to furnish 50 changes at a total cost of frame and letters of about $1,400 for the season of 1899, exclusive of the labor of changing the signs. This makes the cost approximately for each sign about $35 or $40, but after this year the average cost per convention will be only about $10. The average sign includes about 7 four-foot, 54 three-foot and 65 two-foot letters, besides punctuation. The current is furnished by the city from its public lighting plant and the average number of lamps which is used is between four and five hundred of four c. p. each. By this method the city extends a direct welcome to each visiting convention. When the writer last visited Detroit, across the face of the city hall was a brightly illuminated sign reading "Welcome Der Allgemeine Arbeiter bund von Michigan."

CLEMENT & GHARKY.—Mr. Edward M. Clement and William D. Gharky have formed a co-partnership for the purpose of patent solicitation with offices in the Stephen Girard Building, Philadelphia, and the McGill Building, Washington, D.C. Mr. Clement received his education at the United States Naval Academy and afterward entered the office of one of the old Washington law firms as a student. In 1890 he entered the U. S. Patent Office as an assistant examiner and in 1891 after a year's experience in hydraulics, was sent to the electrical division, where he remained for nearly seven years. During this time he had charge at

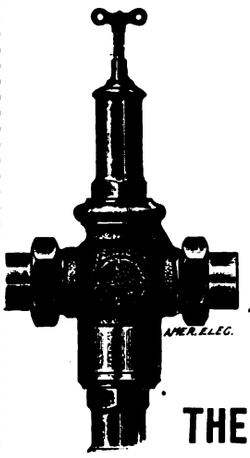
different itmes of telephonic and telegraphic work particularly, but examined cases in all classes. He resigned about a year ago and opened an office in the McGill Building, Washington.

Mr. Gharky has been identified with engineering, chiefly of an electrical nature, since his boyhood. He was connected with the Edison interests in the early days, and served successively with several concerns as an engineer. Among others he was with the Field Engineering Company, and later one of the engineering staff of the Philadelphia Traction Company. In 1897 he was Assistant Superintendent of lines and cables for the Union Traction Company, which controls over five hundred miles of line. He resigned this position to enter practice for himself.



P & B INSULATING MATERIALS.—The letters P & B are so well known to electrical engineers and workmen that it seems almost useless to publish any information about the materials associated with them. But many engineers familiar with P & B compound may be surprised to learn how many varied materials the Standard Paint Company of New York City makes and lists under these two mascot letters. P & B ruberoid motor cloth for motor curtains, piazza decks, etc., is light, durable, odorless and clean to handle, contains no tar, and is water, acid and alkali proof. The P & B insulating tape contains nothing which will vulcanize under exposure to the weather or to heat and is water-proof, so that it loses none of its valuable properties when used in submerged or underground work, and the wires will not oxidize or corrode from contact with it. P & B armature and field coil varnish gives a hard, glossy surface which does not soften at any temperature up to 300 degrees. It is absolutely moisture-proof and has insulating properties which prevent it from cracking or flaking. Armatures insulated with it and P & B insulating paper are highly invulnerable. The Standard Paint Company also makes P & B preservative paint for coating the butts of poles, underground conduits and other surfaces which should be prevented from rot and decay. The company announces that the ruberoid cloth and insulating tape are meeting with an unusual demand this year.

## THE CENTRAL STATION OF THE LOUISVILLE ELECTRIC LIGHT COMPANY.

**A Description of a Comprehensive System Generating Alternating, 500-Volt Power And Series Arc Current.**

BY GEORGE WILBUR HUBLEY.

The Louisville Electric Light Company was organized during the year of 1883, with a capital stock of $100,000. Its first installation consisted of an arc lighting plant, having one 150 h. p. engine of the Corliss type, and six 20-light "United States" low-tension arc dynamos. During the year of 1892 the old Brush Electric Company of Louisville was absorbed and to-day, as the outcome of the original equipment, the plant is of such proportions as to represent an investment of about one million dollars.

The present officers of the company are: A. H. Barret, President and General Manager; Harry Bishop, Vice-President; and J. H. Gilbert, Secretary.

The present plant of the Louisville Electric Light Company, which was built during the years 1890-1891 by Drach and Thomas as architects, is located on Magazine Street, between Fourteenth and Fifteenth Streets, Louisville, Kentucky. It consists now of the original structure with an extension which has been required by the increasing business. The construction of this building is worthy of note, being strictly fire-proof and of iron girder and column arrangement such that the entire weight of the building and its contents is supported by the iron columns from foundations, the brickwork in no manner being called upon for strength or support, other than its own weight.

The main building proper is a three-story structure, one hundred and forty feet in length, sixty-five feet in width and sixty-five feet in height. To the east, adjoining this building, are the boiler room and coal storage rooms, which form a two-story structure of similar construction. On the north end of the main build-

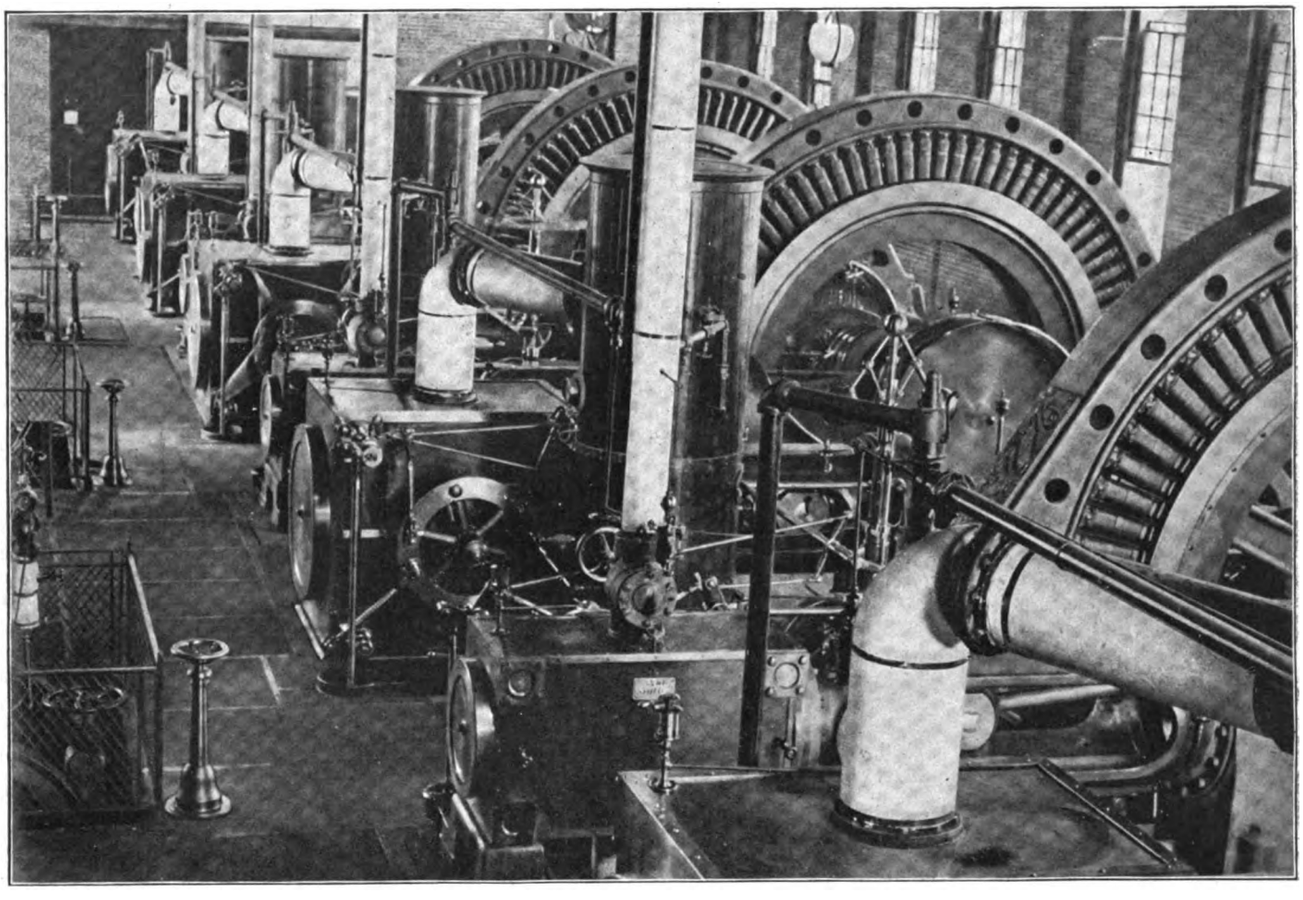

FIG. 1.—THE FOUR DIRECT COUPLED CORLISS ENGINES AND ALTERNATORS IN THE NEW ENGINE ROOM.

ing the extension of the plant adjoins, forming the addition used exclusively for direct-connected generators. This addition is constructed of similar materials as are used in the other buildings, with which its appearance harmonizes well. This new building measures one hundred and fifty-six feet in length and fifty-four feet in width, and the entire interior is

Digitized by Google

one spacious room, open to the ridge pole of a trussed slate roof, which is sixty-two feet above the floor of the plant.

Although this station was constructed about eight years ago it can undoubtedly lay claim at the present day to being one of the most substantial and complete central stations in this country. In fact the solutions of the problems in its original construction, under the direction of Mr. A. H. Barret, by whom its main features were designed, give it a place among the first of modern central stations, as judged from an engineering standpoint.

The station has no architectural pretensions, being of plain brick and iron girders on masonry foundations. The most striking exterior feature is the immense octagonal brick chimney, two hundred and fifteen feet high, with a base twenty-two feet square, and an inside diameter of thirteen feet.

### THE COAL HANDLING EQUIPMENT AND BOILER DEPARTMENT.

The most important labor saving appendages to the station are the coal elevators and conveying apparatus. This apparatus, manufactured by the Jeffrey Manufacturing Company of Columbus, Ohio, was placed by Grainger and Company, of Louisville, Kentucky, and consists of four endless sprocket chains with buckets every third link, which hoist the coal from a pit below the level of the boiler room floor to a height of fifty feet, from which it is conveyed by endless belts to points convenient over coal hoppers feeding the boilers. These elevators and belts are driven by a 15-h. p. C. & C. 500-volt, direct-current motor, which is located in the dynamo room and there controlled, with an additional switch in its circuit placed in the boiler-room, to be used in case of emergency.

A fifth elevator, similar to those used for hoisting coal, is used for hoisting and loading ashes to car from basement. The weights of coal and ashes are carefully registered by large Fairbanks scales, and a daily record is kept of the same. The general arrangement of the coal handling equipment is most complete, and has proven in the service of the past eight years to be highly satisfactory in all respects.

Eight boilers of the water-tube Babcock and Wilcox type, with triple drums, are used. The normal rating is 300 h. p. each, on the basis of an evaporation of thirty pounds of water per horse power hour. The boilers are fitted with Roney stokers and furnaces and deliver gases to the chimney through a flue, lined with fire brick, which is eight feet six inches by seven feet six inches in section.

The boiler drums are covered with two inches of magnesia covering, and all steam and hot water pipes are also covered with similar material.

Fig. 3 shows a view from the south end of the boiler room, showing the railroad switch, the coal pits, the coal elevators and a portion of the boilers with their coal hoppers, stokers, etc. The stokers are at the present time operated by small Kriebel single-cylinder, vertical engines, but these are soon to be displaced by electric motors, which, for auxiliary work in the station, have proven more economical, reliable and satisfactory.

The coal used is nut and slack from mines in Eastern Kentucky, operated by the Central Coal and Iron Company, and is a grade averaging about 11,000 B. T. U. However, the economy with this coal has proven good, due to its use with mechanical stokers and a careful study of its combustion under the best conditions.

A special feature of the boiler department is the very complete system of purification of feed water. The water system of the station will be more fully described later on in this article, but the method adopted for purification of boiler feed water appeals for special mention. The "raw" water contains about fifty-four grains per gallon of foreign matter consisting principally of carbonates of calcium and magnesium, making its use for steam purposes prohibitive. Originally, three Hoppes live-steam purifiers of 1000 h. p. each were installed; and an additional system of water purification,

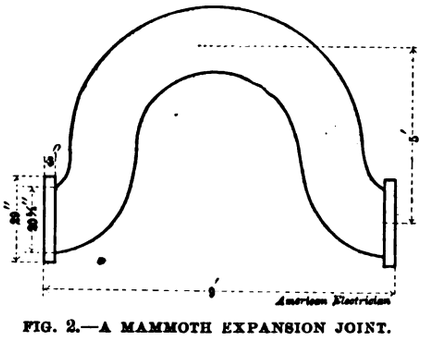

FIG. 2.—A MAMMOTH EXPANSION JOINT.

as manufactured by the We-Fu-Go Company, Cincinnati, Ohio, was added, and is used in conjunction with the Hoppes purifiers.

The following is a brief outline of the process of treatment by this combined apparatus: The raw water is pumped from the hot well, after having been used for condensing purposes, to a tank of 40,000 gallons capacity. It is then treated at its hot-well temperature (110° F.) by chemicals in a simple and practical manner. After the water is allowed to settle from four to six hours, it has been clarified and purified. From the tank it passes through an automatic valve into a gravity filter of quartz, and then is pumped by the boiler feed pump into the Hoppes purifiers, and thence by gravity feed supplies the boilers.

Fig. 6 shows a view of the We-Fu-Go purifying system. Two tanks are used, each of 40,000 gallons capacity, which give a total capacity of 160,000 gallons of water per day (allowing six hours for treatment and precipitation per tank). Two duplex steam-driven pumps, manufactured by the Gordon Steam Pump Company, Hamilton, Ohio, are used for water feed for boilers.

### ENGINE DEPARTMENT.

This department consists of two divisions, known as the new and old engine rooms, according to their priority; they are connected by an opening at the north end of the old engine room.

A 20-in. main steam line extends the full length along the eastern side of the old engine room and enters the addition, connecting with another line of the same size, extending the full length of the southern side of the new engine room. A duplicate 20-in. main steam line parallels the first line the full length of the old engine room, and this line is interconnected with the first line, and by means of valves provides against interruption in case of any accident or emergency that might arise, or in case of necessary repairs on steam lines. By such arrangement the main steam lines of the station are sub-divided into five independent sections that may be operated independently or collectively, as circumstances may dictate, thus giving great flexibility in the operation of the steam distributing system. These steam lines are supported about twenty feet above the level of the floor of the engine room by cast-iron columns from foundations in the basement.

Each boiler supplies steam at 160 lbs. per sq. in. pressure to the main steam line by an 8-in. steam pipe, connected into an angle valve placed in the engine room. All steam pipes and fittings are extra heavy and of special construction.

In the first main steam line is a hammered copper expansion joint of special construction, which is probably the largest expansion joint ever installed. A sketch of this expansion joint showing dimensions, etc., is shown in Fig. 2. This joint was constructed entirely of copper, hammered to a gauge thickness of one-fourth inch, and has a total weight of 1500 lbs. It was put through most severe tests previous to being placed, under guarantee to withstand such test conditions.

Each engine is connected with the main steam line by an 8-in. pipe, with its own valve in addition to the throttle valve at the engine. The entire system of high-pressure steam lines is relieved of all water from condensation by a complete system of "bleeders" that are connected with the Holly system, which returns this water at nearly boiler temperature to the boilers. The condensation of the low-pressure steam lines is trapped and drained to a receiver in the basement. An automatic valve, operated by the water level in this receiver, controls a small pump which pumps water at almost steam temperature back to the boilers.

All engines are operated condensing, and the supply of water for this purpose is approximately two million gallons per day. In a pump well, forty feet below the condensers, is installed a duplex condensing pump, made by the Gordon Steam Pump Company, and with a rated capacity of 2,500,000 gallons per day. The supply of water is obtained from a deep well adjacent to the pump well, and of the same depth. Thirty 8-in. tubes have been sunk to a depth of thirty feet below the level of the pump, or a total distance of seventy feet below the surface. The

Digitized by Google

water is pumped to reservoirs of a total capacity of 150,000 gallons, which quantity is at all times maintained in reserve in case of emergency or breakdown.

Three 20-in. & 40-in.x48-in. 68 r. p. m. and one 12-in. & 24-in.x36-in. 78 r. p. m. Hamilton-Corliss tandem compound engines, manufactured by the Hooven-Owens-Rentschler Company, of Hamilton, Ohio, are employed in the old engine room. The three large engines are connected by three-ply 60-in. Munson belts, each to its respective line of jack shafting, located on the third floor of the building. The third line of jack shafting is divided into two sections by a main friction clutch coupling.

To one of these sections, from which the "all day" dynamos are operated, the small engine is connected by a two-ply 30-in. Munson belt to a special "quill" pulley.

These engines operate condensing, each having its own condenser and air pump, which is direct-connected to the engine. In addition to these three individual condensers these engines are each connected with one main condenser and pump, of ample capacity for the three, manufactured by the Dean Brothers Steam Pump Works, Indianapolis, Indiana. This main condenser is located in the basement under the old engine room and is provided for emergencies and the failure of the individual condensers.

The three lines of shafting are located on the third floor of the main building.

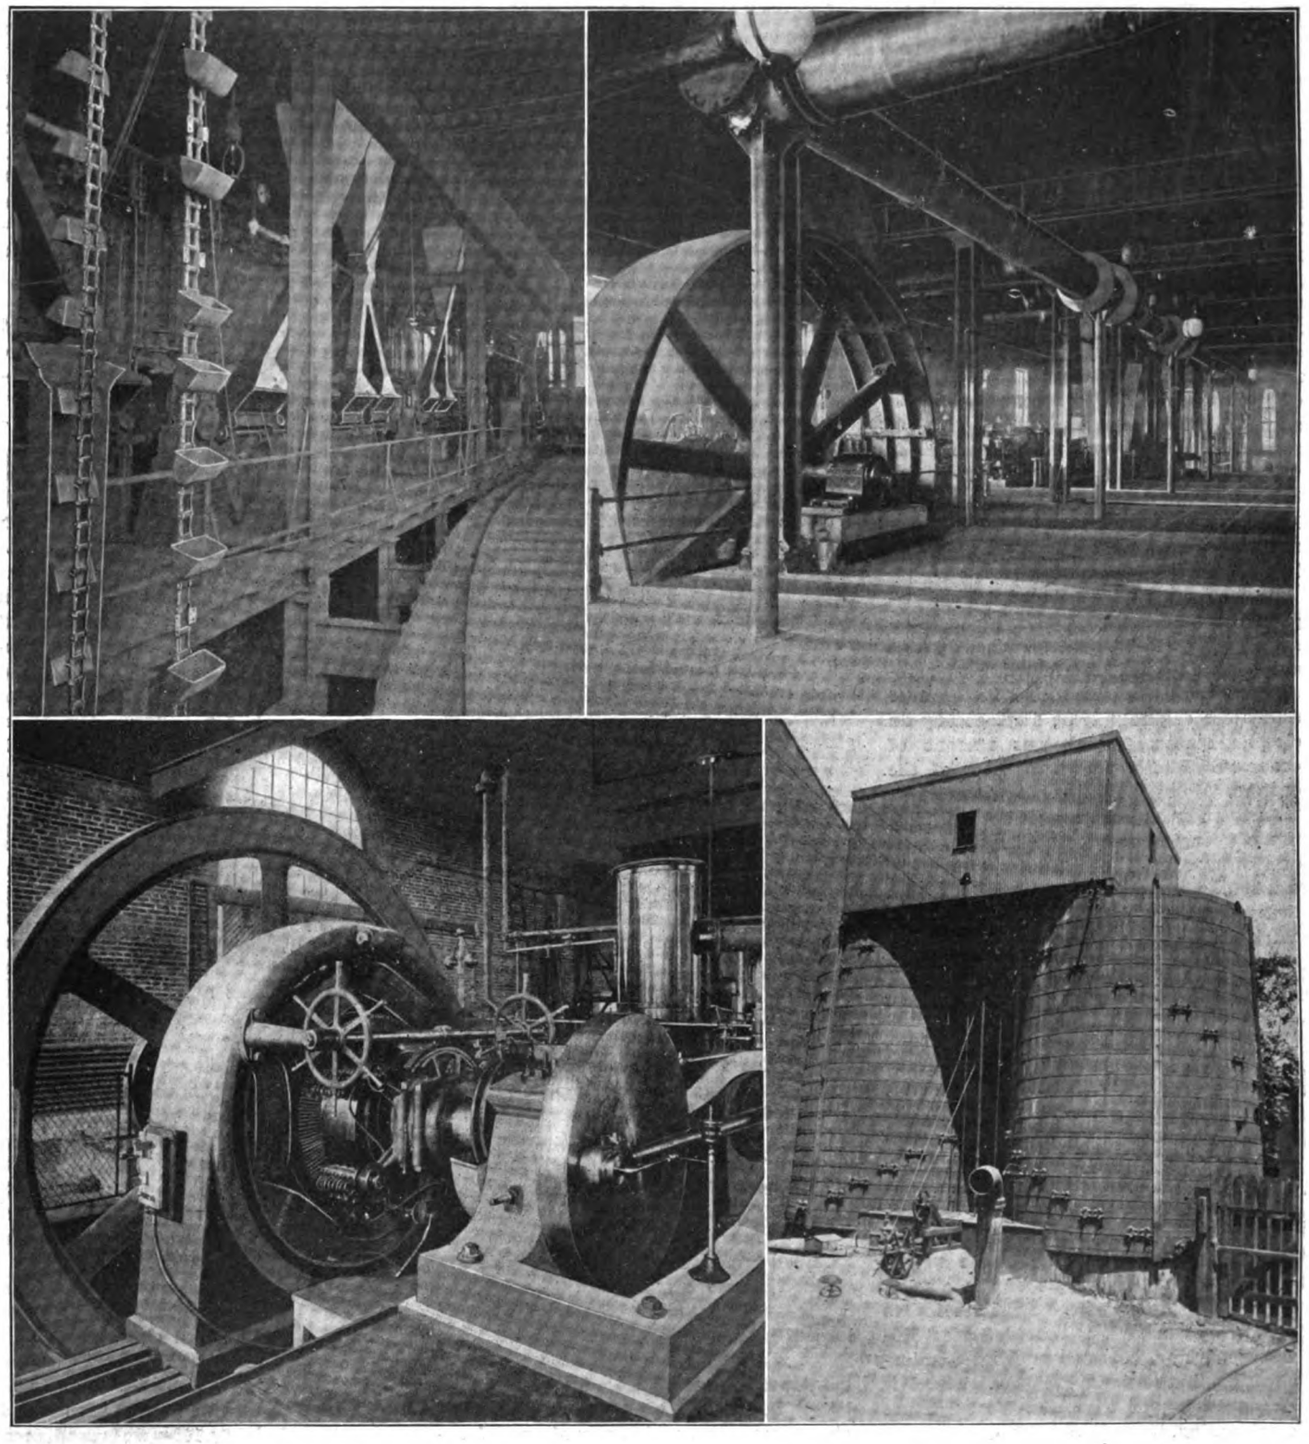

FIG. 3.—VIEW OF COAL ELEVATORS, ETC., IN BOILER ROOM.

FIG. 4.—VIEW OF OLD ENGINE ROOM.
FIG. 6.—THE WE-FU-GO WATER PURIFIERS.

Digitized by Google

and directly over the old engine room. These countershafts are each fifty-four feet in length and seven inches in diameter, and are supported by eight large pillow block journal bearings. Each shaft is equipped with its engine pulley, with a 62-in. face and 48 ins. in diameter; also twelve pulleys, 52 ins. in diameter and 12½ ins. face, these small pulleys being loose on the shaft and controlled by friction clutches. The shafting and its equipment were manufactured by the Falls Rivet and Machine Company of Cuyahoga Falls, Ohio.

The lubrication of the shafting is accomplished by a system of gravity feed, the oil flowing through piping from a tank placed above the shafting. The oil, after passing through the bearings, etc., passes through pipes to a cistern on the first floor. From this cistern it is pumped constantly to the tank above. The oiling arrangements on the engines are such that oil used is drained to reservoirs, which at regular intervals are emptied into filters, and in this manner the same oil is used without much waste. The engine cylinders are lubricated by the use of Rochester lubricators, which have advantages over other methods, being positive in feed and economical in use of oil.

In the southwest corner of the old engine room is a Crane elevator of six thousand pounds load capacity, used exclusively for freight. This elevator at present is operated by steam, but in the near future the engine will be displaced by an electric motor, for obvious reasons of economy. Fig. 4 shows a view of the eastern side of the old engine room.

As the new engine room is entered from the old engine room, the impression is one of awe, and the contrast is most marked. Here the massive engines, with their direct-connected generators, plainly mark an epoch in electrical engineering, as relates to design and construction of the central station.

Near the entrance is the McIntosh and Seymour vertical cross-compound engine, 18 ins. and 36 ins. by 36 ins., speed 100 r. p. m. On its shaft, direct-connected, is a General Electric 400-kw, 500-volt, direct-current generator. Immediately facing this machine to the north is an Allis-Corliss horizontal cross-compound engine, to which is direct connected a Westinghouse 400-kw., 500-volt d. c. generator. These machines are used for the supply of 500-volt power service of the station during the day. The all-night service is supplied by a 75-kw. United States 500-volt generator, belt driven from countershafting in the main building. Fig. 5 is an engraving of the Allis-Westinghouse combination.

In line with this Allis engine are four Allis-Corliss cross-compound horizontal engines, each direct connected with a 500-kw. Westinghouse alternator. These machines supply single-phase alternating current at 2200 volts, primary potential.

As these four engines with their alternators are exactly alike, the description of a single unit will suffice for all. The engines are each astride of their generators—that is, the low-pressure cylinder, guides and crank shaft are on the collector or commutator side of the generator, and the high-pressure cylinder, etc., are on the other side. This arrangement eases the bearings, avoids flexural strains on the shaft and tends to smooth and easy operation. Steam is supplied to the high-pressure cylinder of these engines through 8-in. steam pipes connected to heavy 20-in. mains running the full length of this room, as previously described. Each engine has its own independent steam-driven air pump and condenser of Reynold's vertical type. For the common overflow a 16-in. cast-iron hub pipe is laid beneath the cellar floor, opening into the hot well in the basement.

For handling the large and heavy apparatus described is a ten-ton Phoenix traveling crane, which permits of the convenient and ready handling of apparatus during necessary repair work, or for the purpose of erecting or dismounting. The floors of the engine rooms are of cast-iron plates set on iron girders, which present a clean and neat appearance, embodied with great strength, as well as being convenient for access below or around machinery.

The engraving, Fig. 7, shows a general view of the interior of the new engine room, taken from the west end of the building, and Fig. 1 shows a similar view, taken from the eastern end of the building, in which the details of these engine-generator units are more clearly defined.

### DYNAMO DEPARTMENT.

The dynamo department occupies the entire second floor of the main building. However, this room properly should be termed the arc department, as it is now used almost exclusively for the arc dynamos, switchboards, etc.

Two Westinghouse multipolar 250-volt d. c. exciters are provided for the excitation of the alternators; however, one of these is of ample capacity to take care of all four alternators, and the second one is provided for emergency or in case of accident. These machines are belt driven from jack shafts and their location is so arranged that one operates from the shaft used for "day service" load, and the other one from shaft used for "night service" load. This arrangement furnishes two distinct sources of power, and admits of load being relieved from time to time between the two exciters.

The switchboard for the alternators is located in the northwest corner of the dynamo room, and is quite elaborate in its construction. A special feature of this board is the double-throw, double-pole circuit switches, which are of special design, with magnetic "blow-outs," for instantaneous breaking and "change over" of circuits. The arrangement of all "live" and moving parts of this high-tension board is such as to have them back of the board, and on the face of the board appear only the face plates, plugs and handles necessary for their control. Flexible cables and plugs are used for connections of circuits to generators. All danger is eliminated, and control of operation is facilitated by these systematic arrangements.

The engraving, Fig. 8, gives a view of this switchboard before it was placed in regular service.

The power switchboard is located in the center of the west side of the dynamo room, and is constructed of "Vermont" marble, supported by iron frame. This switchboard is employed in the control of the 500-volt and the 220-volt circuits, of which there are five of the former and three of the latter. The three 500-volt generators described are connected to bus bars on this board, and the 220-volt circuits are supplied with current from two Westinghouse multipolar dynamos of the "Kodak" type.

Twenty 80-light and one 125-light Wood arc dynamos and three 65-light Brush arc dynamos comprise the arc lighting equipment of this station. These dynamos, aggregating a total capacity of 1920 arc lamps of nominally 2000 c. p. each, are operated at a constant current of 9.6 amperes. The arc dynamos are each belt connected with a loose pulley, controlled by friction clutch on line of jack shafting. Each machine is independently controlled by means of lever arm extensions from the friction clutch of its "driver" pulley. Each of these pulleys is also provided with a braking device, controlled from the dynamo room by an extended lever arm. This device was specially designed for this station, and insures positiveness and quick action in stopping of the pulley and its dynamo, when necessary.

The arc switchboard is located in the center of the south end of the dynamo room. An interesting feature of this switchboard is the testing appliances, which are of the company's special design. These consist of a recording voltmeter, calibrated so that a reading as high as 6500 volts may be registered, and a recording ammeter registering continuously the current on the circuit. This ammeter and voltmeter are connected by means of plugs and flexible cables into the circuit, and a continuous record of volts and amperes is registered on a chart. The "Bristol" instruments are used in this application. These daily records on charts are kept on file. The practical value of these arrangements are obvious.

In addition there are for testing purposes plugs for connection of magnetos to indicate open or closed circuits on lines, by means of which hourly records of condition of lines are obtained. Also, a plug connection is provided to a lamp board, consisting of eighty 100-volt incandescent lamps in series, for testing and indicating grounds on circuits. By such method the extent and approximate location of a ground can be ascertained.

The eighty 100-volt incandescent lamps in series are so connected with an 80-point sliding contact switch that all or any number of the lamps may be thrown "in series" across the circuit to be tested. In

Digitized by Google

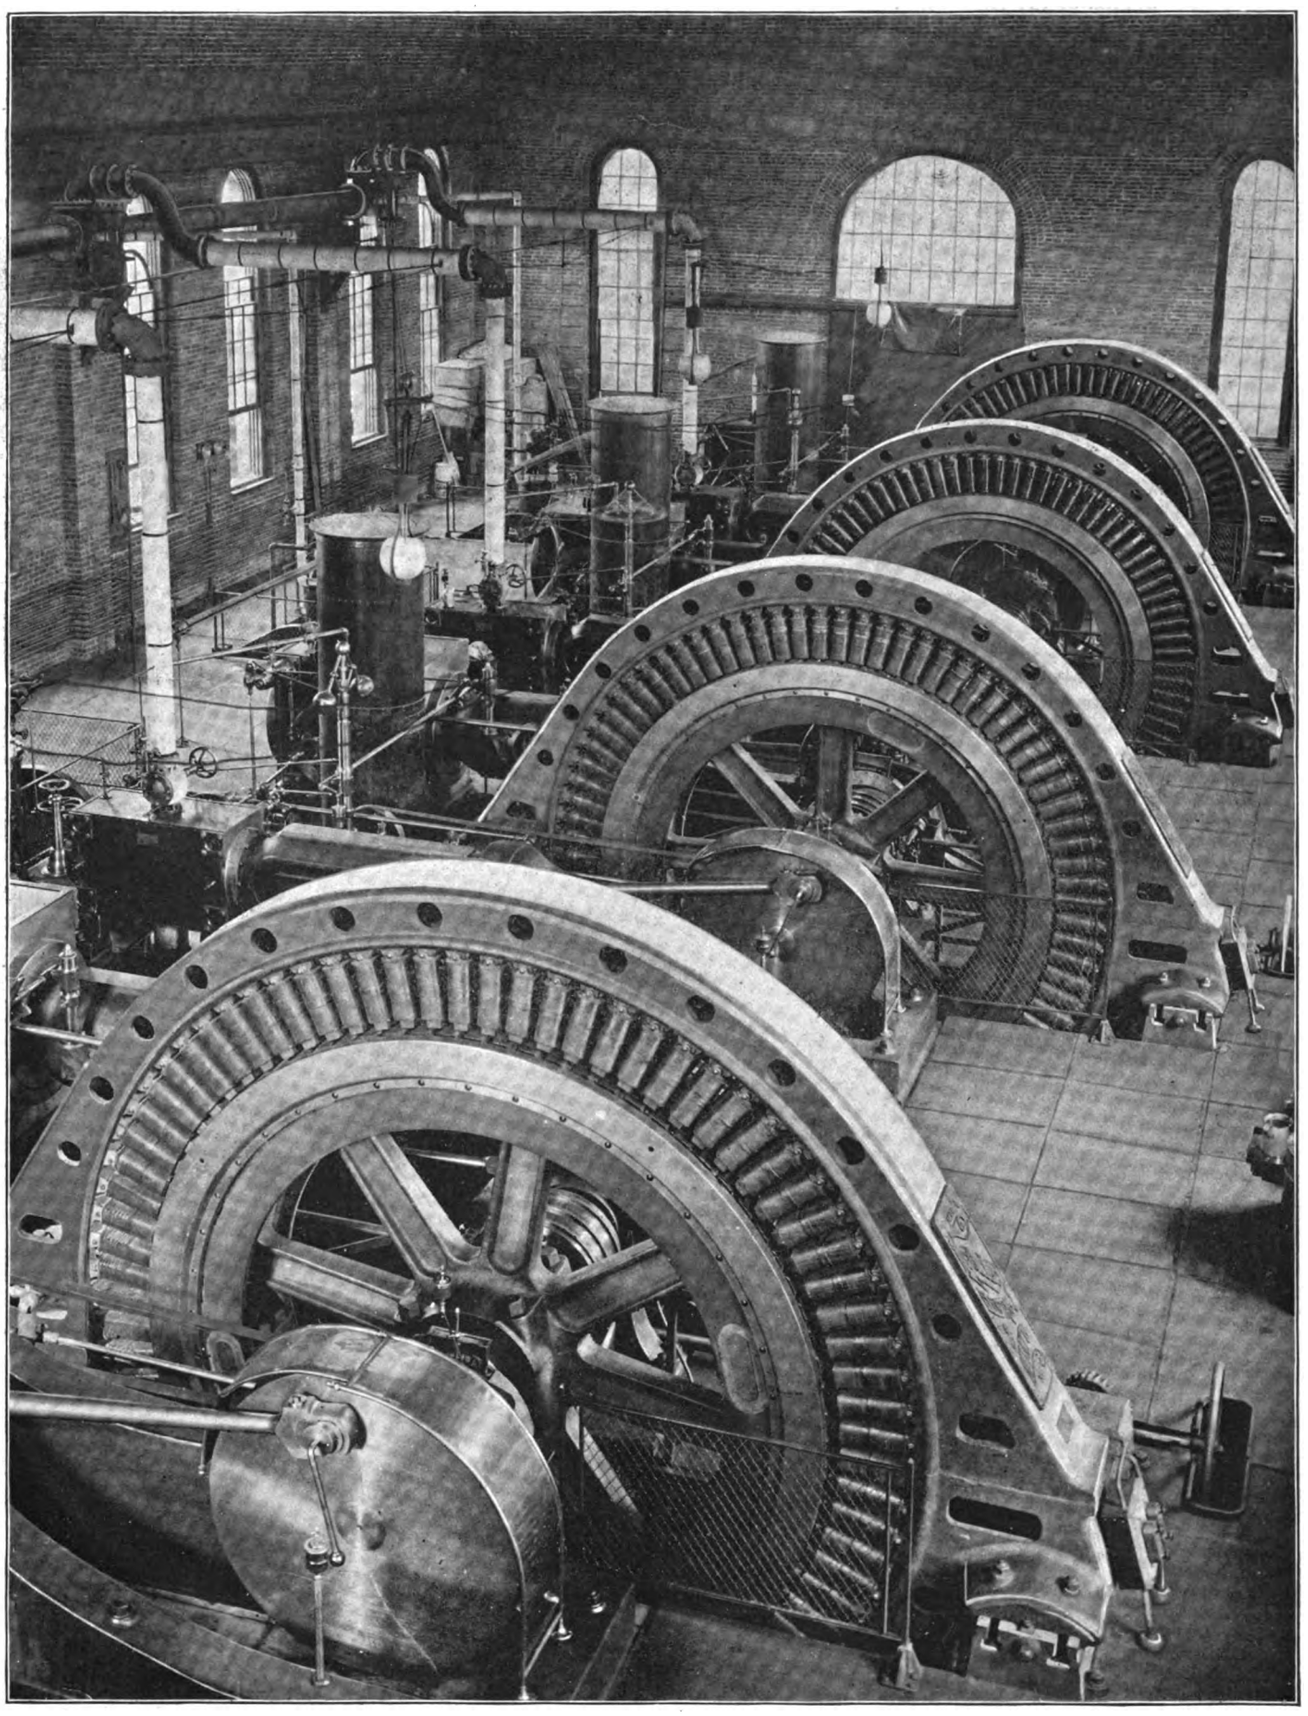

FIG. 7.—A VIEW OF THE NEW ENGINE ROOM, SHOWING THE FOUR ALTERNATORS DIRECT COUPLED TO CORLISS ENGINES.

Digitized by Google

the use of this lamp board for testing of grounds, one terminal of the lamp board is connected to ground and the other terminal to the side of the arc circuit that is grounded, with all 80 lamps in series. Then the switch of lamp board is turned gradually, cutting out lamps in test board until the remaining lamps are brought up to candle power, 100 volts per lamp; then the product of number of lamps burning on test board by 100 volts indicates the total voltage of ground, and consequently its relative location from station.

Fig. 9 gives a partial view of the arc department, taken from an elevation in the southeast corner of the room.

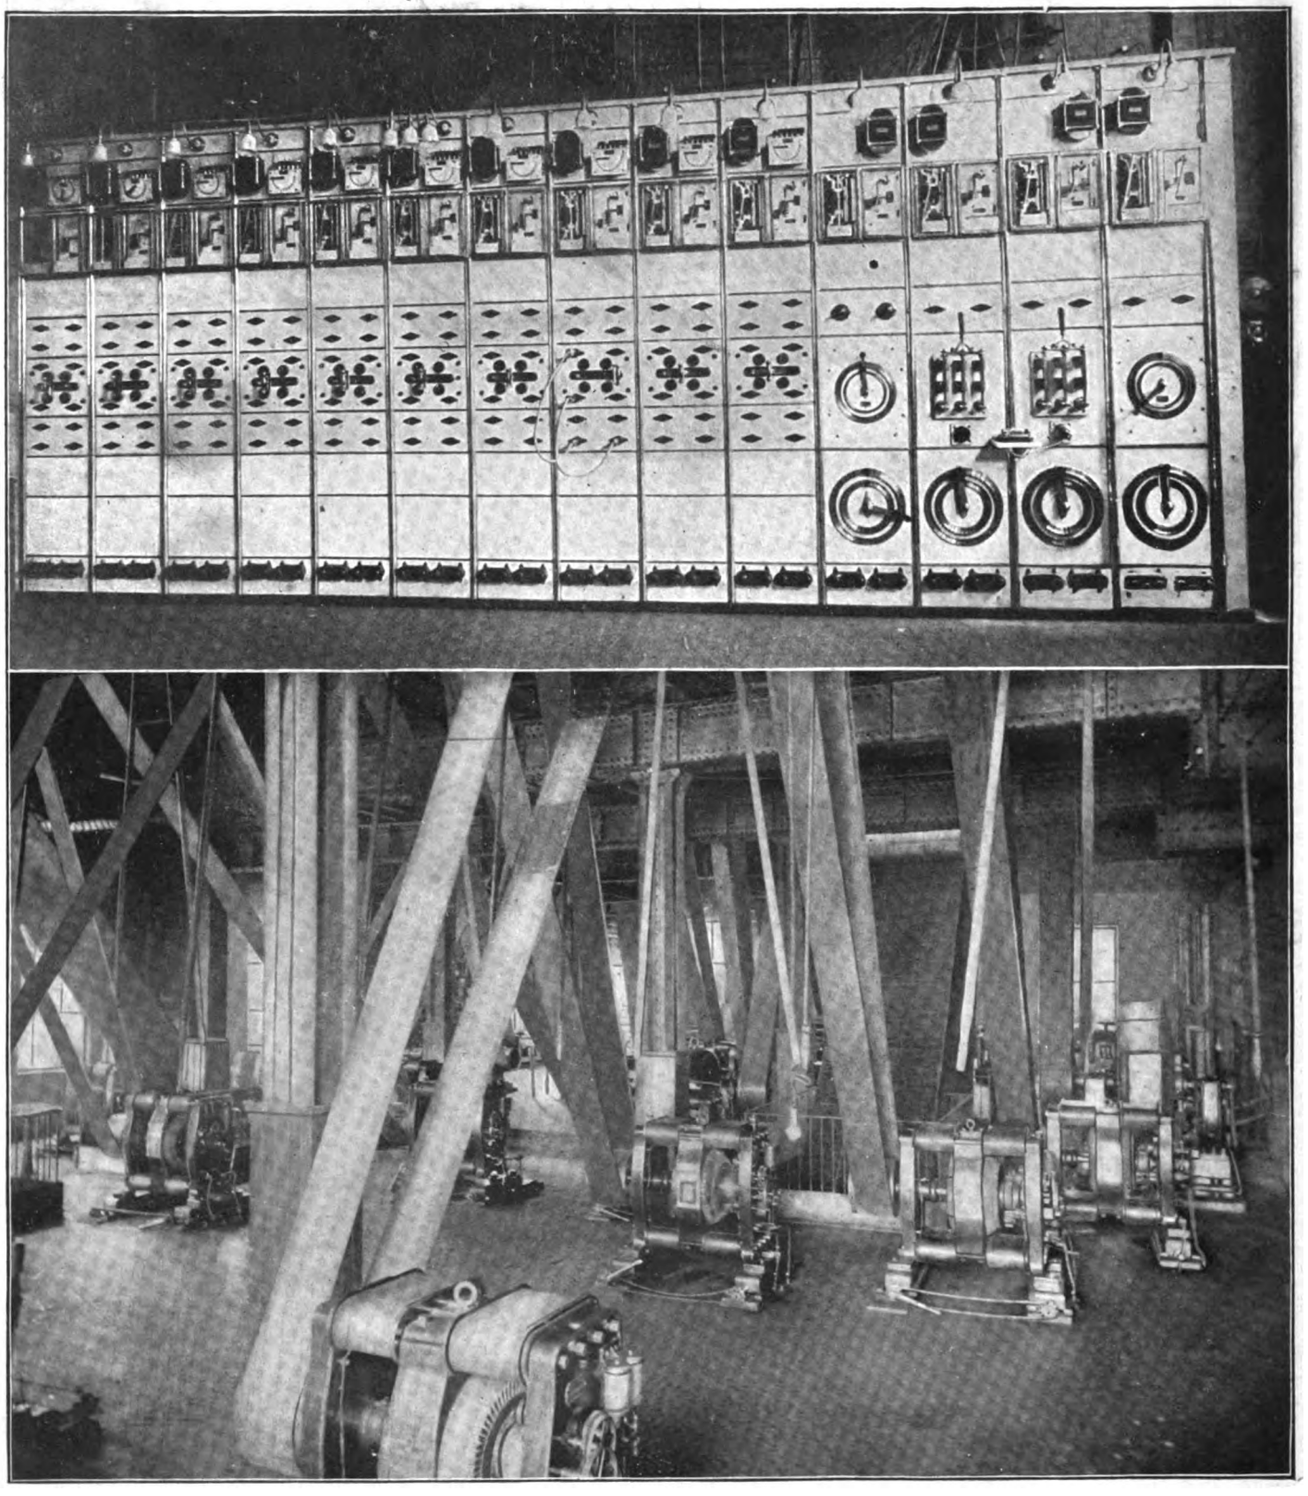

FIG. 8.—THE SWITCHBOARD OF THE ALTERNATING GENERATOR.
FIG. 9.—THE ARC DYNAMOS BELTED TO COUNTERSHAFT ON FLOOR ABOVE.

For cleaning and blowing out the dust, etc., from dynamos and other apparatus, an air blast with a pressure of 20 lbs. per sq. in. is used. This air pressure is maintained in a receiver, erected for the purpose, by means of a Crane automatic air pump. This receiver is connected by piping to convenient points in various departments of the station, and such arrangement greatly facilitates and insures thoroughness in this essential work. A whistle used for signaling purposes between the engine and dynamo departments is also operated by this air pressure, and its further application will probably be made in blowing tubes in boilers,

Digitized by Google

although under the present practice, steam is employed for this purpose.

REPAIR AND TESTING DEPARTMENT.

On the third floor of the main building are located the repair and testing rooms of the station. These departments have had special and most careful attention, and have developed into much importance by the economies derived therefrom. Such work is conducted directly under the personal supervision of the superintendent.

All repair work of the station, as well as reconstruction work, is most efficiently handled. The combination of repairs and testing, under a complete system, has resulted in many improvements being adopted, and consequent reduction in cost of operation as well as maintenance. General repairs are made on armatures, transformers, arc lamps, meters, etc. Under the systematic plan adopted, periodical attention is given to these details, and a general inspection, cleaning, reassembling and testing complete is made at regular intervals on all apparatus employed, thus accomplishing the desired condition of maintaining apparatus up to a standard, and having records of its exact condition.

The testing department is a special and important feature of the station, being designed in view of practicability and simplicity. The testing work of the station is done with much facility, being reduced to a mechanical basis of work. Currents for testing purposes as high as 10,000 volts and 1000 amperes can be readily obtained. All apparatus, details and supplies employed in the station work are tested under requirements as set forth in specifications. Some years ago this station adopted this policy in purchasing new apparatus and supplies. All testing is conducted in this department with the exception of incandescent lamp tests, which are made at the general offices of the company, where a standard Bunsen photometer is located.

The pressure of 10,000 volts and currents of 1000 amperes mentioned are obtained by transformers from alternating lines; however, the station also is equipped with direct current for testing purposes within limits of 550 volts e. m. f. and 750 amperes current, and in handling such currents water rheostats are employed, as well as a novel and specially constructed resistance board consisting of 432 ½-in.x12-in. carbons.

The carbons are arranged in horizontal rows of nine carbons to each row and forty-eight rows. The connections between carbons are made by lead terminals moulded on each end of carbon, and the various rows are connected in multiple or series as desired by flexible cables to bus bars running vertical on the resistance rack. Each carbon has resistance of .11 ohms, making a total resistance when all are connected in series of 47.52 ohms. By the various combinations that can be made in connection on this improvised testing rack, it has proven a most convenient and valuable adjunct in testing department. The carbon resistance will withstand extremely high temperature, and another advantage is its low temperature coefficient.

STOREROOMS, OFFICE, ETC.

The balance of the space on the third floor of the station is occupied by store rooms and the superintendent's office.

The station office fills a position of importance in the plant, and emanating from this department the complete control of the comprehensive system described is maintained. Recording instruments of various kinds for registering pressure of steam, amperes and volts on various circuits are employed, furnishing daily registered actual records of the station operation. These are carefully preserved, in addition to the compiled data carefully and systematically recorded and filed from day to day.

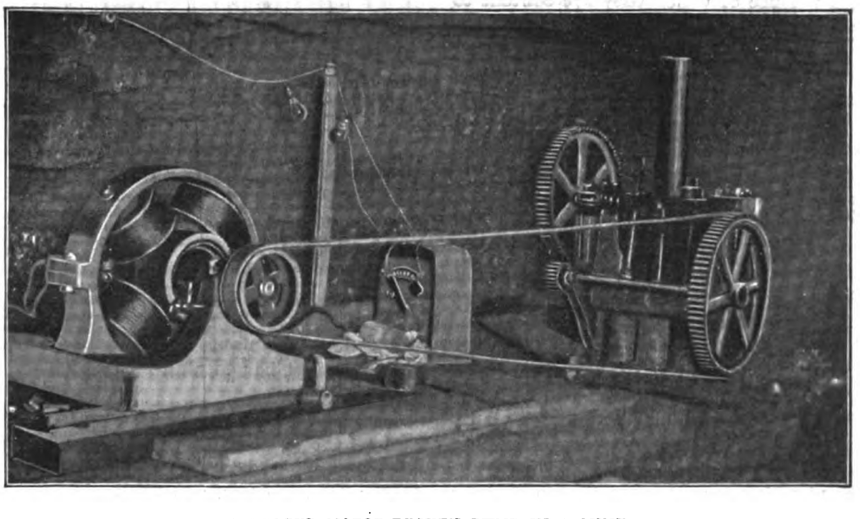
DISTRIBUTION SYSTEM.

The overhead distributing system is of a high standard of excellence in its construction, insulation and general appearance. Some conception of its magnitude may be appreciated by the brief statement that this distribution system employs in main feeder lines a total length of about 400 miles of copper wire, the alternating service using about 50 miles of No. 00 and No. 0000, power service about 70 miles of No. 00 and No. 0000 feeders, and the arc service about 280 miles of No. 4 lines.

Many special features in details of line construction, arc lamp suspension and banking of transformers are of interest, but lack of space prevents detailed descriptions of these points. The high standard of construction and maintenance of lines attest the capabilities of Mr. W. O. Smith, under whose direction and charge this important work is conducted.

In conclusion, apologies are made for some of the engravings illustrating this article, owing to the photographs having been taken at the time of reconstruction, when much temporary work existed, detracting from the appearance which the station presents at the present day.

# Electrical Installation in Coal Mines.



BY HARRY N. GARDNER

It is doubtful if in any branch of electrical application more complex problems have confronted the engineer than in that of work in mines, especially in the coal fields. Particularly can this be said of the anthracite region of Pennsylvania.

These problems, much more than those of many others applying to industrial electrical engineering, have presented conditions difficult of solution, influenced by commercial antipathies, ignorance and prejudice, and hostility of labor interests. And the strictly engineering questions that have had to be solved have been more numerous than in almost any other one field. In many ways they combine the conditions met with in the use of electrical power in mills, electric lighting and electrical railroading; and in this age of specializing each of these fields has already presented enough questions to demand its specialists.

The advantages of the use of electricity in various ways in coal mining are as certain as in any of the other larger fields; only the proportionate saving is not so great, the advantages are less marked and the prejudices to overcome have been greater.

With the adoption of electricity on street railroads about the only class of individuals to be injured was the horse raisers, particularly on the vast Western ranges. And it was not until electric cars were whizzing through the streets of most American cities, and they suddenly found that there was no market for their thousands of horses, that the horse raisers re-

A BELTED MOTOR-DRIVEN PUMP IN A MINE.

Digitized by Google

alized their danger; and it was then too late to even try to stop the advance of the new power.

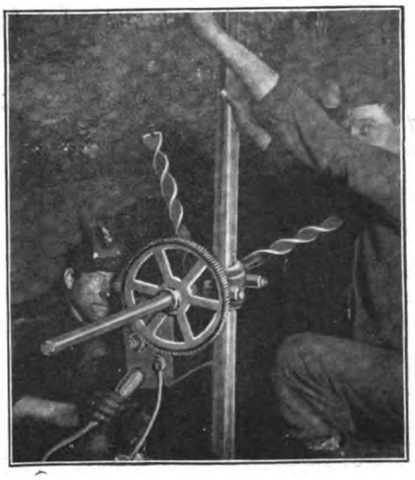
Many farmers in the middle west engage in raising mules for mine use, and there are mule dealers who buy the animals of the raisers and sell them to the mine owners. These men, strange as it may seem, have undoubtedly succeeded in doing much to impede the introduction of electricity into the mines. Some of these dealers have made fortunes in this line of trading, and are closely related to leading coal operators or superintendents of company mines, and their influence in preventing the advance of an improvement that would ruin their business has been greater than might be supposed.

Another thing that has deterred many individual operators from installing electrical plants is the large first cost. During the past six years the individual coal operators have been so held down by the transportation companies that their profits have been less than they desired. And it is difficult to persuade a man to install a $10,000 plant, partially as an experiment, at a time when his profits are falling off.

The conditions vary greatly and it is certain that in some mines a great saving could be affected by the introduction of electricity, while in others small economy would result. Inasmuch as the success of electrical operation has not been as great in some mines as was anticipated, all mine owners are slower to take advantage of the improvement than they would otherwise have been.

Again, the operators who have found a substantial saving in this method of operation are loath to give out information concerning the cost. And should inquiries be made, they strive to disparage the system the use of which they are content to continue.

Many of the mines are operated by steam railroad companies, and there is a natural feeling of hostility to electric traction on the part of managers of these companies that has had its influence in retarding the introduction of electricity into the mines.



Each of these causes is small in itself; but taken in the aggregate, they have exerted an influence felt to such an extent that at present only about twenty-five out of several hundred mines in the Carbondale, Scranton and Wyoming districts have electric plants to assist in their operation. The fact that more operators than ever are now figuring on such plants and that companies with several mines, where sample plants have been installed, are planning for others, seems to promise well for this branch of the electrical industry.

From the strictly engineering standpoint, one of the first questions presented in this branch of work is to design special machinery that will be of use and stand abuse; for in hardly any other place is electrical machinery subjected to harder usage than in mining work.

The generator, particularly where electrical haulage is used, must be so designed that it will stand all manner of sudden changes from no load to a heavy overload. The dancing of an ammeter needle in a railroad power house is slight compared to one in a mining plant, particularly if two locomotives are used, and the dynamo is run from no load to a heavy overload and back again in a few seconds.

Fuel for steam generation for mine work is considered to cost nothing, so that economy in steam generation is the last thing thought of. And the steam traps of boilers and engines that are operated in many places are enough to bankrupt any firm that had to pay for coal. The unwritten law of mine operation is founded on dirt. It is impossible to keep anything clean around a mine or coal breaker; and no operator would consider the wheels of his industry properly moving unless they were hidden in coal dust.

The first thing that the electrical engineer has to figure on is the location of his generating plant. Some mine owners, who will pay $3,000 a year for board and

A MOTOR-DRIVEN DRILL.

a suite of rooms at a fashionable hotel, or $50,000 for election to Congress, will hesitate about putting up a $200 wooden building for an electric power house, trying instead to locate the plant in a dirty corner of the boiler room or shaft house, and run it from the old unsteady engines already in use. A building or room for the generating plant being secured, the engineer next has to plan on the voltage to be used.

In mines where electric haulage is used mules have to assist by bringing out cars form the chambers to the main gangways. Most mines are low, and the mules, men and boys are liable to come in contact with the trolley wire. For this reason, if the distance will permit, most engineers prefer a 220 or 300-volt plant. Should the increased cost of copper for a long transmission line make it necessary, a 500-volt current is used.

Strange as it may seem, however, about as many mules have been killed on circuits operated at 220 as at 500 volts. One case of such electrocution on a 220-volt circuit in a Carbondale mine afforded much satisfaction to the mine employees, if not to the owners. A particularly vicious mule had a habit, when mad, of biting whatever she could get hold of. If a man or boy was not handy, she would seize anything else. One day, while the driver boy was whipping her, the only thing that she could reach to bite was the trolley wire over her head. She seized that, settled back on her haunches, and without being able to spit out her mouthful, slowly burned to death.

When the "juice" is first turned into a mine, the employees usually give it a wide berth. The feeling of fear soon passes off, however, and the men get so that they little mind an occasional shaking up, even from a 500-volt circuit. In mines where 220 volts are used, the driver boys soon find a peculiar use for the current. A piece of wire, insulated for handling, but bared at the ends, and with one end bent so that it can be hooked over the trolley wire, makes a good substitute for the cruel "blacksnakes" which they unmercifully apply for accelerating mule speed. The manual labor of pricking up a mule with the end of the wire is less than by wielding the whip, and the sport afforded is much greater.

The transmission line combines many of the problems of interior wiring and exterior line work. Running the line from the generating point to the head of the shaft or mouth of the slope is much the same as ordinary line work. But the lineman or wireman who has run 4-0 feeders around steam pipes and up an ordinary elevator shaft appreciates something of the work required to run such a line down a 300 or 400 foot shaft into a mine.

In this work frequently too little care is used in properly placing the lines, and the grounds from improper insulation detract from the later working of the system. It is usually possible to attach ordinary wooden brackets to the shaft timbers for supports, and the regular petticoat glass insulators are used.

As soon as the foot of the shaft is reached plans have to be made for running the wires along the sides or roof of a coal or rock tunnel, and this necessitates a large amount of drilling and plugging.

In all mines a gutter-like waterway is dug or blasted out at one side. The mules and men always walk in the middle or at the other side of the tunnel. It is accordingly customary to run the transmission line along the side or roof of the mine, directly over the waterway. The trolley wire is also suspended from the roof at the extreme corner over the waterway; and for this reason the trolley poles of mine locomotives are placed at one side.

Supports for the wires are fastened into the rock or coal every twenty-five or fifty feet, according to the contour of the mine walls and roof. Two holes are drilled for each wooden support, and different kinds of wooden and metallic plugs have been devised for fastening these blocks to the

Digitized by Google

walls. Sometimes ordinary wooden plugs are used, and the blocks are screwed up with lag bolts. The more satisfactory method is by the use of a special split taper iron plug.

Either heavy porcelain or glass insulators are fastened to these supports for the feeder wires, and the trolley wire is fastened to the blocks by means of the ordinary bell insulator trolley support. The rails are bonded the same as for surface traction for the return current.

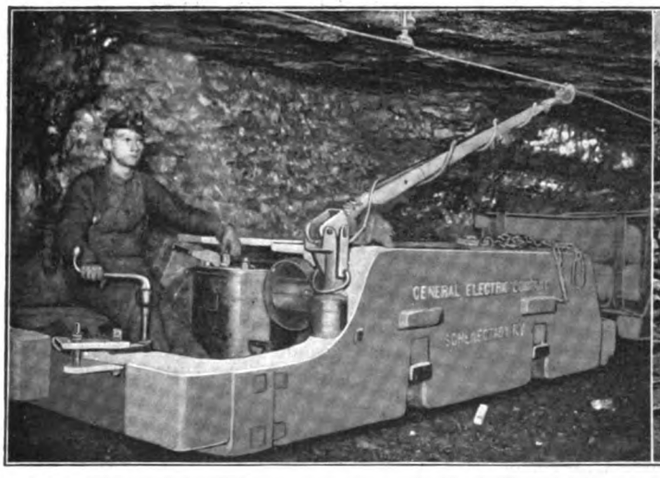
The motor of a mine locomotive has to be constructed to stand even more heavy use and abuse than the ordinary street car motor. There is always much moisture in a mine, and the fine coal dust, everywhere encountered, is most penetrating, and is liable at all times to cause trouble to commutator or armature winding.

One work in which electricity has been found most efficient in the mines is for pump operation. It is much more easy to run a line of feeder wire than half a mile or a mile of steam piping; and the electric motor has been found a much more trusty operator of mine pumps than the small steam engines commonly employed, especially where the pump runs part of the time on air; and they perform their work with much less attention.

It is necessary to frequently change the location of pumps in mines. The pump and driving motor are accordingly mounted on a small car and by an easy change of feeder wires they can be drawn to any part of the mine and left to perform their work without attention. In a mine some time ago visited one of these small motors was found out near the end of the tunnel, far from the point where the nearest workman was employed. The only attention that it received was a monthly oiling.

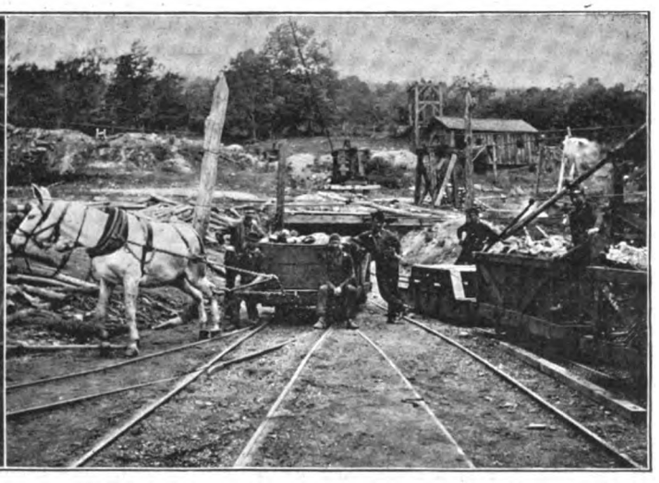
Electric lighting has been employed in many mines to light certain parts of the main tunnels. The lamps are run in series, the number in a series depending on the voltage employed. The safety of electric lighting over the ordinary miner's lamp, for mines where fire damp is encountered, has been urged; but the method has been little employed for general mine lighting.

Electric drills have been found to greatly reduce the cost of driving tunnels in mines where it is necessary to remove much rock, as is frequently the case. For drilling in coal, a hole can be driven by hand nearly as fast as it is possible to move and set up the drill, either method requiring the services of two men. The drill motor has to be entirely encased in iron, and made so that it can be dragged over rocks and mud in the most careless manner.



Even with the protected motors employed for all kinds of mine work, it is easy for employees, who are opposed to this system, to produce accidents with a frequency that has a discouraging influence on the introduction into mines of this power. Mine employees have looked upon the introduction of electricity into mines with much suspicion, fearing that it means the reduction of the working force. It is to electric drills, where used for rock work, that the most objection is made. And it is these machines that are the most liable to develop faults. Two men with such a drill can sometimes do the work of six men by the old method. And it is easy for a drill motor to be burned out, the drill broken or bent, or some other accident happen to the implement that will incapacitate it for service.

One cause that has helped to keep electric mine service from being as efficient as it would otherwise be is the management to which such plants are subjected after being installed. It frequently happens that a young man, who has had just enough experienec as a helper to cause him to call himself an "electrician," is employed to take charge of the electric plant. He is employed because he will work for $40 or $50 a month, when a competent man would cost $60 or $75; and he is expected to attend to the running of the dynamo and make all repairs to the machinery or lines.



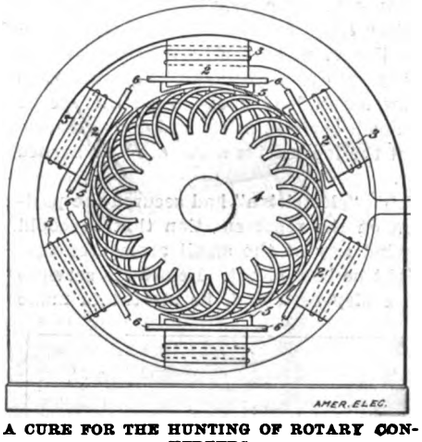
The work of one such "electrician" in a mine in the Lackawanna valley will illustrate the practical working of such economy. It had been necessary to make some changes to the circuits in the mines. There were frequent breaks to the wires, caused either through accident or intent of prejudiced laborers. Wherever it was necessary to make a splice, this "electrician" found it was much easier to make a "flying" one by simply bending the ends of the wires and hooking them together. In a few months these "flying connections" in the feeders were numerous. The pressure used was 220 volts, and the end of the tunnel was some distance from the foot of the shaft, so that the increased resistance of these poor connections resulted in a large voltage drop, and it was impossible to make the locomotive draw as many cars as it should. The attempt to draw a full load necessitated the use of so much current, at the reduced pressure, that the locomotive armature was burned out.

This "electrician" had secured the position on the representation that he could rewind any of the small armatures that might be burned out. Before his services were dispensed with he started to make such repairs, with the result that his successor found three dismantled small motors, the armatures of which he had tried to wind without success.

The employment of a competent man as electrician of this plant soon demonstrated that it was not the fault of electricity itself that had caused the mine owners to look upon the system almost as a failure.

A MINING LOCOMOTIVE.

HORSE AND ELECTRIC TRACTION.



## Automobiles for Mail Collection.

The Postmaster of Buffalo, N. Y., has experimented with a borrowed automobile trap in the collection of mails from letter boxes. One route 18 miles in length with 40 boxes was covered with the automobile in 1 hour and 30 minutes, the same road with a horse and wagon requiring more than 3 hours. Other tests made July 2d and 4th showed a similar reduction of the time of collection. A specially designed automobile fitted with a box for receiving the mails has been ordered and will be put into service as soon as received and complete tests made with it.

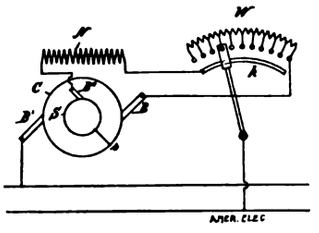
# Some Recent Electrical Patents.



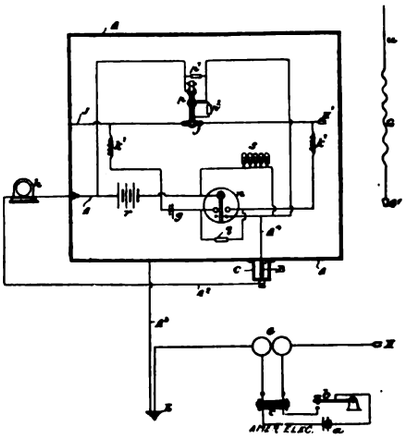
**A Cure for the Hunting of Rotary Converters.**—One of the most troublesome actions of alternating-current synchronous motors, and particularly of rotary converters, especially on systems supplied with power from steam engines, is the so-called "pumping." This consists of an oscillation of the armature superposed

A CURE FOR THE HUNTING OF ROTARY CONVERTERS.

upon its continuous rotation, that is to say, at one instant the armature speeds up and at another slows down, the action at times becoming so violent that the machine breaks out of step or synchronism with the system. A machine running alone never pumps, but two machines are likely to pump together, one speeding up as the other slows down, and vice versa, especially if the two machines are of about the same size and are separated from each other electrically by transformers and a transmission line. It is found that the pumping is accompanied by a shifting of the lines of force across the faces of the field magnet poles. When the machine speeds up the magnetism travels forward to the leading horns of the field poles and when it slows down travels back to the following horns. Mr. B. G. Lamme has accordingly invented a device for reducing the pumping by checking this traveling of the lines of force, which device is now quite generally used on rotary converters made by the Westinghouse Electric & Manufacturing Company. The arrangement is shown in the accompanying diagram, in which the device proper is designated by the figure 5. It consists of a strap around the pole with a shoe or extension coming into the air gap under the horn of the pole piece and covering a part of the area across which the lines of force shift. These straps are cross-connected at the ends, forming short circuited coils, so that any shifting of the lines of force is dampened or checked by the generation of foucault currents in these straps. A recent French design for the same purpose goes further and slots or tunnels the whole pole face, inserting therein a regular squirrel cage winding such as is used in induction motors. Patent No. 626,172.

**A New Field Connection.**—Small direct current machines with high voltages, if shunt wound, require a very fine wire in their field coils which increases the cost of construction as well as the bulk of the coil, owing to the large amount of insulation, and owing to its delicacy renders the machine liable to injury. Prof. Adolf Sengel of the Electrotechnical Institute of Darmstadt has patented an extremely simple means of cutting in two the voltage applied to the shunt winding, thereby allowing its cross section to be doubled, its number of turns to be reduced 50 per cent. and its resistance to be reduced 75 per cent. Incidentally the improvement is a great advantage in the starting of shunt-wound motors. The invention consists in connecting one end of the shunt field windings as usual to one of the lines and the other to a single collector ring tapped in at any point to the armature winding. When the machine is running at full speed the field is thus subjected to a fluctuating electromotive force, its instantaneous value changing every revolution from the full e. m. f. across the terminals of the machine to zero and

A NEW FIELD CONNECTION.



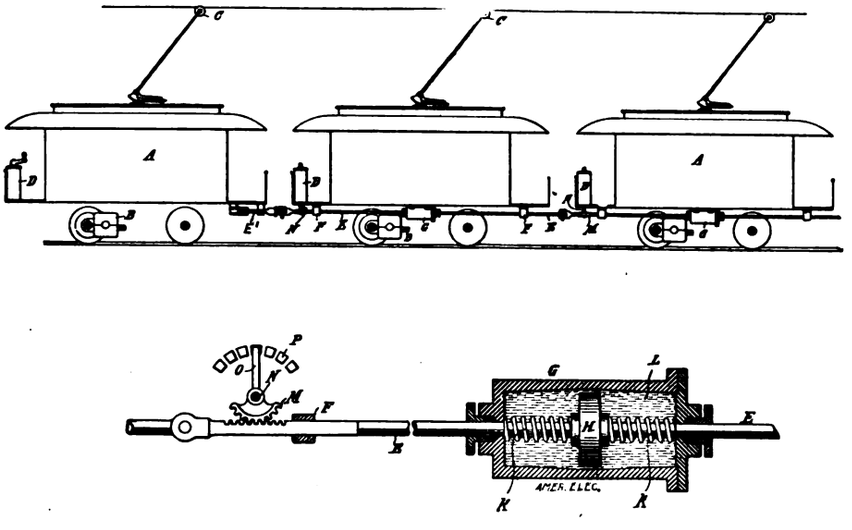
back again. The general arrangement of the apparatus is shown in the accompanying diagram in which N is the shunt field connected between the outside terminal of the armature rheostat W and the brush B′ bearing on the collector ring S, which is connected to the armature winding at the point s. Obviously when the resistance W is all cut out s will be in contact with B at one instant and with B′ at another instant. In the first case there will be no e. m. f. across the field windings and in the second case the full e. m. f. of the machine. This fluctuating e. m. f affects an inductive circuit, such as a field winding, as though it were a direct e. m. f. of half the full strength on which is superposed an alternating e. m. f. The latter will be choked back by the self induction of the field winding, while the former will magnetize it. In starting a shunt motor, while the machine is at low speed the fall of potential is mainly in the starting rheostat W, around which the field winding is obviously shunted. The field will thus get in starting double its normal e. m. f., which will gradually be reduced as the speed comes up, giving a considerable increase of the field strength in starting and a corresponding reduction of the number of amperes required to start a given load. For the brief time of starting the motor the field will easily stand this double current strength. Patent No. 624,986.

**The Marconi Patent on Wireless Telegraph Apparatus.**—A patent on the details for protecting the coherer from the fierce Hertz waves sent out from a transmitter at the same station has been granted to the now famous worker in wireless telegraphy, Mr. Guglielmo Marconi and assigned to the Wireless Telegraph & Signal Company, Ltd., of London. While the patent apparently has no value, as its claims are limited to combinations of many parts, some of which are unessential, still its drawings give some idea of the arrangement of Mr. Marconi's apparatus.

Referring to the accompanying diagram, u is the aerial wire connected through a flexible cord, G, with a plug, G′, which can be inserted in the spring clip, H, for transmitting, or in the spring clip, $H^1$, for receiving. In the former position it is connected to ground through the sparking balls, e, forming the terminals of the secondary of the induction coil, C, fitted with battery and key for transmission in the well known way.

The coherer, its tapper, relay, batteries, resistances and choking coils are all enclosed in an iron case, A, a suitable thickness for which is given as 1/20 of an inch. Through an opening in this case the connection from the aerial cord may be plugged, as mentioned above, connecting to the clip, $H^1$, and thence to the coherer, j, and through wire, J, to the iron case, which is grounded. Shunted around the coherer is the relay, n, with choking coils, $kk^1$, to prevent the oscillatory currents from passing through the relay winding.

A single cell battery, g, is connected in the circuit through the coherer and relay



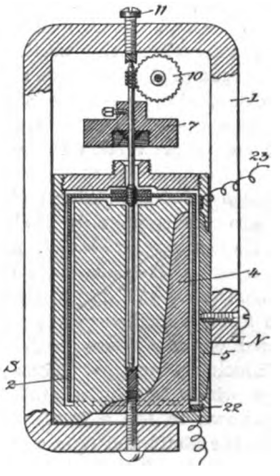
THE MARCONI PATENT ON WIRELESS TELEGRAPH APPARATUS.

coils. The contacts of the relay are connected to the battery, r, and thence up to the tapper, p, and through a ground on the enclosing case to the sounder, h, which is preferably located outside the case. The return wire from the sounder passes through the choking coil, B, which the patent states may contain about 20

Digitized by Google

yds. of wire 1/75th of an inch in diameter and having 120 turns. The wire is covered with tin foil, which is connected with the iron box, the purpose of which is to prevent the oscillatory currents set up in the sounder circuit from entering and disturbing the apparatus inside. The contacts and coil of the tapper are shunted by resistances, $p^1p^2$, and the contacts of the relay are shunted by the resistance, s, to prevent sparking at these points, which might itself set up feeble waves which would affect the coherer in close proximity. Patent No. 624,516.

**A Simple Multiple Unit Controlling System.**—In the operation of electrically driven trains with motors on two or more of the cars it becomes necessary to install quite complicated apparatus for assuring the positive control of these various motors simultaneously from any desired point, usually the head of the train. Such systems have been designed, notably by Mr. F. J. Sprague, as well as by the engineers of the General Electric and

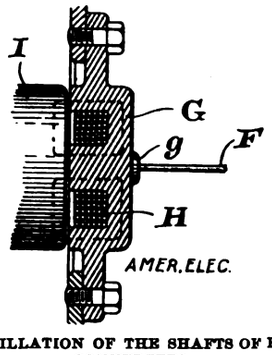


A SIMPLE MULTIPLE UNIT CONTROLLING SYSTEM.

Westinghouse companies. A very simple plan for making the draw bars of the cars themselves the means of transmitting the impulses has been patented by Mr. H. S. Maxim. As shown in the accompanying diagram, there is a sort of continuous draw bar, E, running through the train and attached to each car by means of a plunger, H, on the draw bar, driving, through springs, K K, the ends of the cylinder, G, attached to the car. The cylinder is also filled with a liquid to prevent sudden oscillations of the piston in the cylinder. The draw bar is also attached to the controlling mechanism by any means such that the movement of the piston from the mean position in the cylinder tends to start the motors in one direction or the other. The general scheme is that on starting the first or leading car in the ordinary way, the forward pull of the draw bar and the drag of the other cars upon it will cause their controller cylinders to be turned to such a point that current will be turned into their motors, tending to drive them with sufficient torque to prevent them from dragging with any considerable force from the leading car. Patent No. 625,454.

**An Alloy of Common Metals with the Coefficient of Expansion of Platinum.**—Since the price of platinum has risen to its present high value of about $18 per troy oz., it has become particularly worth while to discover other metals that will take its place. One of the greatest demands for platinum is the construction of such articles as incandescent lamps, where a metal must be incorporated with glass. The value of platinum for this purpose is due to the fact that its coefficient of expansion is the same as that of glass, and therefore when an incandescent lamp is heated both platinum and glass expand together, causing no breakage of the glass and no separation of one material from the other to allow air leakage. Hitherto no other satisfactory metal has been found for this purpose. C. E. Guillaume of Switzerland and L. C. Dumas of France claim in a recent patent to have discovered that alloys of nickel and steel expand and contract under variations of temperature in a peculiar way, differing from the manner of either metal separately. By varying the proportions an alloy may be obtained with any desired coefficient within certain limits. With small proportions of nickel the coefficient of expansion is between that of iron and that of nickel, rising as the proportion of nickel is increased, until, with 23 per cent. of nickel, it reaches its maximum, approximately that of brass. As the proportion of nickel is further increased the coefficient of expansion diminishes progressively until, when the nickel reaches about 37 per cent., it becomes practically nil. Beyond this proportion the coefficient increases progressively and becomes approximately equal to that of platinum when the amount of nickel used in the alloy is 45 per cent. The first claim of the patent reads: "An alloy of nickel and iron having the same coefficient of expansion as glass, substantially as described." Patent No. 626,655.

**A Direct Current Meter Motor with Mercury Commutation.**—For the metering of direct currents instruments of the motor type have practically driven from the field all other varieties of meters. They require, however, commutators, which are the source of their greatest troubles. The commutators must be practically frictionless and yet have sufficient pressure on the brushes to avoid open circuit or sparking in case dirt or dust accumulates. Mr. E. S. Halsey has patented a motor for this purpose in which the commutation is done by means of mercury, giving a fluid friction which is constant and negligible at low speeds, rising with the speed, thereby acting in part as a suitable brake. A further braking effect is obtained in the usual way by means of foucault currents, which are generated in the same conductor that carries the current, the same permanent magnet thereby giving the field for both the motor and brake. The meter has therefore no shunt circuit as has an integrating

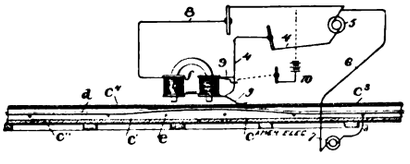


A DIRECT CURRENT METER MOTOR WITH MERCURY COMMUTATION.

wattmeter, but is an integrating ammeter. Its losses on open circuit are zero. The general design is shown in the accompanying vertical section, in which 1 is the magnet screwed at one end to the pole piece, 5, opposite the opposing pole piece, 4. Between these two runs the inverted cup of copper, 2, suspended on a shaft, 9, connected by a worm wheel with the usual train of gears, 10. The inverted cup runs in a chamber which is filled full of mercury for the purpose mentioned above, as well as for floating its weight, which it does so effectively that a counterweight, 7, must be added to prevent upward pressure against the upper bearing. The current is introduced at 22 and taken out at 23, flowing through the mercury and in large part, owing to its lower resistance, through the copper of the cup. This gives a turning movement to both the mercury and the copper, this moment being proportional to the current flowing, giving the parts a proper speed to integrate the load. Tests described and plot-

Digitized by Google

ted in the patent specifications show a remarkable accuracy at low loads—a 25-ampere meter being only 1 per cent. slow with 1 ampere and 5 per cent. slow with ½ ampere. Patent No. 626,832.



**The Oscillation of the Shafts of Rotary Converters.**—To avoid the grooving of commutators or collector rings on dynamo machines due to brushes constantly traveling in the same path over the face

THE OSCILLATION OF THE SHAFTS OF ROTARY CONVERTERS.

of the copper, it is customary to leave a little end play in the shaft and allow it to oscillate back and forth. In mechanically driven machines this oscillation is, as a rule, accomplished without any special apparatus, simply by the axial mechanical forces of the belt or connecting rods. In rotary converters the armature is likely to run without any endwise oscillation and the commutator and collector rings are correspondingly likely to develop bad grooves. Mr. E. W. Rice has patented a device for constantly oscillating the shafts of such machines axially back and forth, which device is now generally used on converters made by the General Electric Company. That part of the device which is attached to the machine is shown in the adjoining cut, in which I is the shaft and G is a cast-iron piece bolted to the frame of the journal. This is cored out to receive the coil shown at H, which, when energized, tends to magnetize the central core and draw toward it the end of the shaft I. This coil, H, is supplied with direct current through wire, F, from an interrupting device which repeatedly turns the current on and off at intervals of a few seconds. Every time the current is turned on the shaft, I, is drawn toward the magnet, and every time it is turned off the shaft is released and moves toward the left. The interrupting device in some installations consists of a commutator driven through a worm gear by a small induction motor. In other cases it consists of a magnet which pulls up a contact, breaking the circuit of the magnet, which then falls again against a dash pot. Patent No. 625,806.

**A Simple Sectional Conductor Railway System.**—One of the most fascinating devices for inventors in the sectional conductor railway field, is a switch under the road bed actuated by the field of force of a magnet carried by the car. A sort of continuous switch of this kind has been patented by Mr. H. Barringer Cox of thermo-electric battery fame. Referring to the adjoining diagram, $c^3$ is the top of the sealed conduit divided into sections insulated from each other by the spaces, $c^4$. Within this sealed conduit is the bare and live conductor or feeder d,

A SIMPLE SECTIONAL CONDUCTOR RAILWAY SYSTEM.

of iron or steel wire or cable, supported on the cross pins, e. The car carries a magnet f, which lifts this live cable into contact with the sectional top of the conduit from which the current is taken by means of the shoe. Unfortunately the invention does not appear to have been broadly patentable, as the claims are limited to the combination of many devices, some of which are unessential. Patent No. 624,304.

# Among our Foreign Contemporaries

**What to Do When a Dynamo Fails to Excite.**—In the case of a self-exciting dynamo which refuses to build up, a number of tests have to be made in order to locate the "trouble," and it is often necessary to make these in a hurry, for which reason it is advisable to make them in the right order. A list of these tests is given in a recent issue of the London Electrical Engineer, and they are briefly as follows: Make sure that the brushes are on the right place on the commutator, and, of course, see that the brushes really touch. Then see that they are set properly, relatively to one another; that is, if there are several sets of brushes see that the distances apart are equal; should the armature have a double winding, the brushes must, of course, cover more than one commutator strip at a time and they must, therefore, be of the proper thickness to do so. Then start the machine and run it at its proper speed; if this does not make it excite then find whether the shunt winding is really connected with the brushes, and if it is then try for ground leakage, which is especially important in the case of a shunt machine, for if the field is short circuited the dynamo will, of course, not excite at all. Then see if there is not a break in the field winding, a fault which is more likely to arise in shunt machines. In looking for possible ground connections it is, of course, desirable to disconnect the machine from the circuits, as one of the two faults may lie outside of the machine. If all this does not help, try changing the shunt connections at the brushes, for if they have been connected wrong it is evident that the machine cannot excite itself; also see to it that the field windings are so connected that they give the proper sequence of poles and are not both north or both south poles. If there are slight signs of a field it may help to connect the two halves of the shunt winding in parallel, if that is possible, as, for instance, if there are two coils to the magnet; this would increase the current in the field; but this, of course, applies only to shunt and not to series wound machines, as in the latter the parallel connection would reduce the ampere turns. Also see to it that the shunt and series windings, if it is a compound machine, are not opposing each other, for in the latter case the machine might run with a few lights but would lose its field as the load is put on. If all this fails to locate the trouble, the armature must be examined; to find short circuited coils in the armature excite the machine separately from some other source and note which sections become overheated. If this does not locate the trouble, then run the machine separately excited at the normal voltage and see if the armature has its normal output; if it has not, and the machine is a new one, there is something wrong with the armature. If this also fails to locate the difficulty the case may be considered a fairly hopeless one, and an expert should be called in.

**The Removal of Wool from Skins by Electricity.**—A process has recently been patented for the above purpose by a means invented by a lady living in Bradford, England. The instrument shown in Fig. 1 consists of an electric cautery

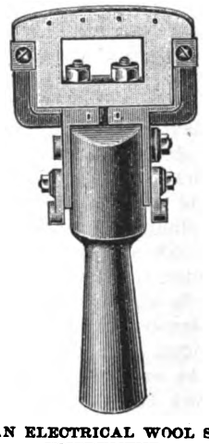


FIG. 1.—AN ELECTRICAL WOOL SHEARING INSTRUMENT.

knife, the cutting of the wool being accomplished by means of a platinum-iridium wire, rendered incandescent by an electric current of about 60 amperes at 4 volts. The red hot wire mows down the wool at a speed so great that the heat in

Digitized by Google

no way injures either the skin or the wool. The process now in use consists of allowing the skin to decompose slightly, after which the wool is torn off by hand. A treatment with lime or other chemicals is sometimes used, but tends to deteriorate both the skin and wool.

**An Electrically Lighted Life Buoy.**—The English electrical papers describe a new form of electrically illuminated life buoy, the invention of a Captain Meller, now being introduced on the British market. The arrangement is shown in Fig. 2, which shows that it consists of a large cork ring of the usual type, provided with a lantern at the top of a tubular pole, the lower end of which is weighted with the accumulator, the latter being specially constructed for the peculiar conditions of continuous charge and very rare discharge. The pole between the accumulator and lantern is attached to the buoy through a universal joint which allows it to remain upright while the buoy floats on the waves. An automatic switch is

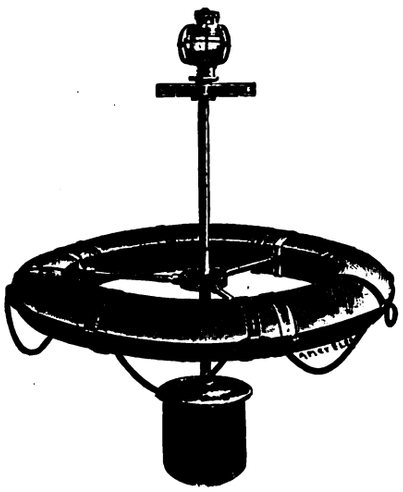

FIG. 2.—AN ELECTRICALLY LIGHTED LIFE BUOY.

provided, so that when the apparatus is out of use and on shipboard the light is turned off, but when the buoy assumes a horizontal position on the surface of the water the light is turned on.

**A Multiple Rate Meter.**—In a general article on the various systems of charging for electrical energy, Messrs. C. E. L. Brown and J. L. Routin describe in "L'Industrie Electrique" a system of their own, intended to go further than the two-rate system used to a certain extent in this country by establishing a large number of rates, increasing as the central station load rises to its daily peak and falling off as the load goes down again. The principle of the apparatus is shown in Fig. 3, in which r is a ratchet wheel driving the meter train, and actuated by the pawl, p. This pawl is attached through the rod, o, to the armature, m, of the magnet, f. One of these magnets is installed in each meter and all are connected between one side of the network and ground. By putting in a storage battery between the same side of the network and ground at the central station and making and breaking the circuit every few seconds the various magnets of the different meters are actuated in unison. The metering is done by the cam-shaped vane, v, which is turned toward the position, $v^1$, as the load increases. The amount by which

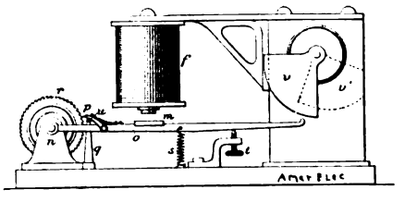

FIG. 3.—MECHANISM OF A MULTIPLE RATE METER.

the pawl can rise depends upon the clearance betwen the right hand end of the rod, o, and the vane, v, and this clearance depends upon the load at that instant. Thus if the magnet, f, is actuated at regular intervals the ratchet wheel, r, will be driven forward an amount dependent upon the position of v, and hence dependent upon the load. The multiple rate feature is introduced by varying the frequency of the impulses given to the magnet, f, by varying the frequency of the contacts to ground at the central station. At times when the load is heavy these contacts are made more frequently, while at times of light load they are comparatively infrequent. Thus the meter train is driven forward more rapidly with a given load upon the meter at any desired time of day than it is at others. The arrangement also contemplates the use of direct currents between the network and ground in case of alternating systems and alternating currents in the case of direct current systems, so that any accidental grounding or leakage on the other side of the system does not affect the apparatus. If an alternating current magnet is used

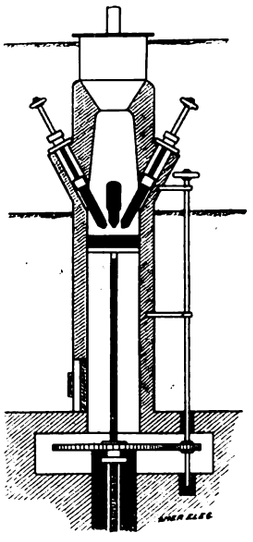

FIG. 4.—SECTION OF A THREE-PHASE FURNACE.

it is put in series with a condensor to shut out direct currents and if a direct current magnet is used it is made of very high self-induction to shut out alternating currents.

**Three-Phase Electric Furnaces.**—In a paper presented before l'Association des Ingenieurs Electriciens de l'Institut Electrotechnique Montefiore, at Liege, Belgium, by M. Segre, there was described a calcium carbide plant at St. Marcel d' Aoste, Italy, of interest because of the use of three-phase currents in each furnace. The general design of the furnaces adapted for these currents is indicated in the vertical section, Fig. 4, which shows the three main terminals of carbon inclined downwardly and inwardly toward a vertically movable carbon plate which may or may not be connected with the central or neutral point of the Y connected supply circuits. The furnace is intended for continuous operation, the position of the parts shown being that at starting, the materials being introduced in briquette form at the top, and the plate being lowered until the finished carbide can be removed piece by piece through a door shown on the lower left hand side, the furnace remaining meanwhile in continuous operation. Between the three main terminals there exist three arcs, or

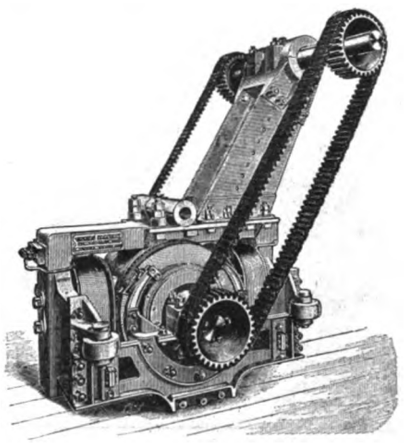

FIG. 5.—THE DRIVING MOTOR OF A BEHR MONORAIL CAR.

what might more properly be considered one rotary arc, which also spreads from these terminals to the conducting mass below. The furnaces are supplied with current at 16 cycles per second. In the paper mentioned many other interesting details were given, among them the preparation of the briquettes, wood charcoal being used to supply the carbon, and other peculiarities which the plant exhibited, a description of which would be too lengthy for these columns.

**Sprocket Chains on Motor-Driven Cars.**—The proposed Behr single-rail lightning express railway between Liverpool and Manchester, on which a speed of 100 miles an hour is to be used, will, if built, make use of electrical and mechanical details similar to those of the Behr railroad at the Brussels exhibition some years ago. An illustration of the motor and chain driving plan of the Brussels type of car is reproduced in Fig. 5, from the "Mechanical Engineer." The chain is of interest owing to the fact that contrary to prevalent ideas it gave very satisfactory

Digitized by Google

service. The car as run in Brussels was driven by four 75-h. p. motors at a speed of 600 r. p. m., giving a chain speed of 2000 ft. per minute. The gear ratio was 1 to 1, and the chain was used in place of connecting rods for fear of the mechanical strains which would be introduced by the latter at high speeds. The chain width was 4 ins. and the cut shows that its arrangement differed from that of sprocket chains commonly used on bicycles in this regard—that the teeth of the sprocket wheels did not enter between the links of the chain, but the latter were U-shaped, fitting over teeth like those of spur gearing. The writer in the contemporary mentioned above stated that the chains were practically noiseless, no sound of working being heard, and if there was any noise it was completely drowned by the hum of the armature.

**A New Method of Assembling Accumulators.**—A new vertical arrangement of accumulator cells is described in the "Electrotechnische Zeitschrift" by A. Tribelhorn of Buenos Ayres, cells arranged

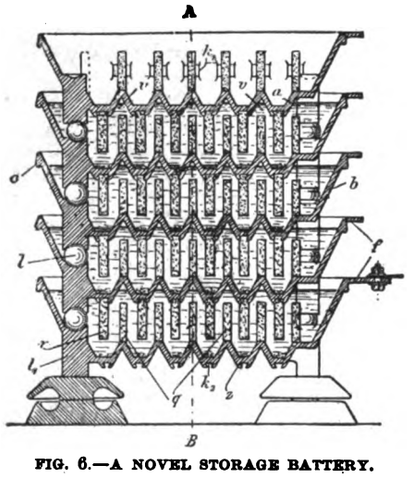

FIG. 6.—A NOVEL STORAGE BATTERY.

in this way being manufactured by Adolph Diener, Zurich. Referring to Fig. 6, the receptacle, $l_1$, is made of lead and has the form of a tray with a corrugated bottom, a. On the four corners are supports which hold the spherical insulators, l, These keep the trays separated, insulated from each other, and in a definite position. Larger trays have a greater number of supports and an extension, c, by means of which the trays can be lifted by a special tool. The strip electrodes, q and v, can be constructed in any known manner. They are attached to the upper and lower corrugations, a, of the bottom in such a way that the positive plate, v, hangs from the bottom and the negative one, q, stands in an upright position. The positive plate is usually fastened by means of dovetail joints, soldering or wedges, the negative one by means of side lugs. The electrodes are put in place in large cells at the place of erection. The trays may be coated with an acid proof paint, or the bottom may be made of sufficient thickness so that the decrease in capacity of the electrodes is compensated for by the increased capacity of the bottom of the trays. Batteries from 1 to 2 ft. in height have been constructed, giving from 30 to 60 volts. The area occupied by such a battery is only double the space taken up by a single accumulator of equal capacity of the old type.

As will be seen, the grooves, z, form canals in which the waste material may accumulate, while the upper grooves, v, serve to conduct away the gases.

The advantages claimed for the new method are as follows: The strip electrodes are more stable than large plates, which are more quickly deformed by the unequal density of the liquid, poor casting, etc. The separate jars being abolished, the insulation of the different cells becomes more certain. There are no soldered connections between the elements. The extraordinary saving in space. It may be claimed that the plates cannot be inspected easily. In answer to this it is claimed that there is no necessity for frequent inspection, as the danger from short circuits and buckling is considerably reduced. Specific gravity determination can be made with ease.

**A Novel Changeable Gear.**—An epicycle gear train, the ratio of which can be changed by tightening or loosening a friction clutch, was described in the "Mechanical Engineer," and has since been commented upon in French and German technical papers. It was designed originally for the back gearing of lathes, but has been found useful in connection with single-phase motors, to one of which it is shown attached in Fig. 7. It should also be a valuable device in automobile work, since the gear ratio can be changed while running and without changing over the teeth of a pinion from mesh with one gear to that of another, which operation

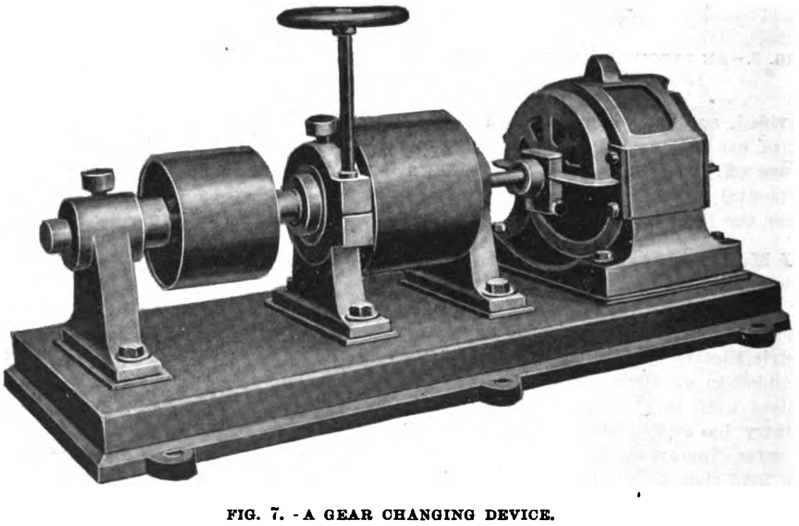

FIG. 7.—A GEAR CHANGING DEVICE.

frequently causes breakage. The nature of the action is a little difficult to understand, but may be explained by reference to the sectional drawing, Fig. 8. Here M is an oil-tight gear case provided with hubs, N and N, which act as bearings for the sleeves, B and G, which are keyed to the driving and driven shafts respectively. On B is a bevel pinion meshing with two beveled gears carried on two inclined shafts, free to rotate within the gear case, M. One of these inclined shafts appears in the illustration, the other being in the lower half of the section. Each of these inclined shafts carries two gears which rotate as one, the larger meshing with both B and H, and the smaller one with the driven member, G. If the outside case is clamped tightly so that it cannot ro-

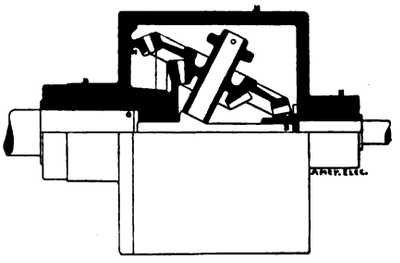

FIG. 8.—SECTION OF CHANGEABLE GEAR.

tate, one speed reduction is obtained, while if it is released and allowed to rotate the speed reduction is greater. By bringing out a sleeve attached to the member carrying the two inclined shafts and clamping this, still a third speed ratio can be obtained. Various other relations of the parts can be made so that other effects can be obtained. For instance, the whole apparatus may be clamped together so that all parts move around as one, the gear ratio in this case being unity.

**The Latest Improved Form of the Aron Integrating Wattmeter.**—In continental Europe clock-work meters are to a large extent used to measure the power delivered to consumer's premises in place of the motor meters almost universally used in this country. The most popular form of these clock-work motors is the Aron meter, the latest form of which is shown in Fig. 9. The principle of the old instruments, as well as the new, is to record the difference in speed between two pendulums, the downward pull of one or both of which is affected by the load upon the meter. These two pendulums are driven by clock-work and together drive a train of recording dials through a differential gear like that of a single motor

Digitized by Google

automobile, so arranged that if the speed of the two pendulums is the same the gear train is not moved, but if either pendulum runs faster than the other the gear train is driven at a speed proportional to the difference. In the wattmeter form the pendulums carry shunt coils below which are series solenoids which pull one shunt coil down and repel the other when current passes through them. As the speed of a pendulum of a given length changes when its downward attraction is changed, the two pendulums will run at different speeds when the load comes on and thereby tend to record it on the dials. It is obvious that friction does not affect the indications of this instrument at low loads, as it does that of motor meters, and that the instrument is as sensitive at no load as at any other. If the two pendulums are not perfectly synchronized they will make a record either forward or backward when there is no load upon the instrument. This is one of the disadvantages of the old instrument overcome in the new, which automatically from time to time reverses the electrical and mechanical connections so that if one pendulum tends inherently to run faster than the other it will drive the gear train forward half the time and backward half the time, leaving a zero record. The instrument is also self-winding by devices similar to those used in self-winding clocks in this country. It also starts itself automatically when the current is turned on, and stops its mechanism automatically when the difference of potential vanishes from its shunt coils.

FIG. 8.—THE ARON METER.

**The Reappearance of the Internal Reflector.**—After irregular intervals there appears on the market an incandescent lamp with a reflector inclosed within the loop of the filament. The latest freak of this kind is a lamp of English make, illustrated in the accompanying cut. Descriptions of the lamp in the pamphlets and other advertising matter devoted to it, state that it contains within the bulb a reflector made of clear glass silvered inside, or of white opaque glass with or without a silver coating on its interior. The claims are made that it intensifies the rays of light, reflecting them out in every direction; that it absorbs heat, which lengthens the life of the filament and occasions a great saving in the consumption of current; that it trebles the light, and also that it is the greatest improvement on the incandescent lamp since its invention. It is obvious that any reflection in one direction must take away from the light sent out in another direction and that no increase in the mean spherical candle power can be effected in this manner. If the reflector absorbs heat it simply reduces the temperature and consequently the efficiency of the filament, unless more energy is delivered to the lamp to maintain the temperature at the proper value for a given brilliancy. The great saving in the consumption of current and the multiplication of the light have been anticipated by many previous inventors, who have spent hard-earned money on experiments in the same line because their inventive faculty was unaccompanied by sufficient knowledge of some of the simplest laws of science.

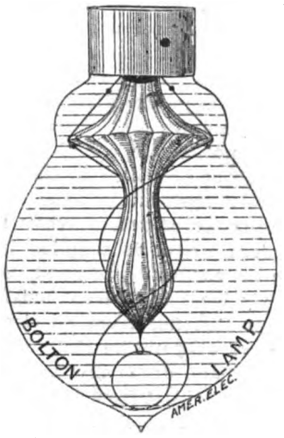

FIG. 9.—AN INCANDESCENT LAMP WITH INTERNAL REFLECTOR.

## NOTES.

**A Floating Electric Light Plant.**—The United States Navy will equip a tug boat called the "Apache" with an electric light plant, which will enable the boat to be used as a light boat for lighting vessels out of commission or that may be undergoing repairs.

**The American Association for the Advancement of Science.**—The forty-eighth annual meeting of this association will be held at Columbus, Ohio, August 19th to 26th, 1899. The association's headquarters will be located at University Hall of the Ohio State University.

**Large Prizes Offered for Inventions.**—President C. J. Glidden of the Erie Telephone & Telegraph Company has stated that he would give $1,000,000 for a telephone repeater as satisfactory as the telegraph relay. He has also made the same offer for a means of quadruplexing telephone instruments.

**A Novelty in Automobiles.**—An electric vehicle manufacturing house in Toronto, Ontario, has constructed a motor-driven invalid's chair, which is unique in being the smallest motor carriage in the world, the width over all being only about 2 ft. It is equipped with 3 cells of storage battery, weighing 33 lbs. and a small motor capable of driving it at a maximum speed of 4½ miles per hour.

**New York to Boston by Trolley.**—A. I. Prime, a New York lawyer, his wife and sister, arrived in Boston on July 13, from New York, having traveled almost the entire distance by trolley. The trip took about twenty-nine hours, exclusive of stops. Two hundred and five miles were covered by trolley and only fifty-two by train. Thirty different lines were passed over.

**A Long Run With an Automobile.**—The longest trip of storage battery automobiles ever reported is that of Comte de Chasseloup Loubet, who drove, July 2d, from Paris to Rouen without recharging, the distance being some 85 miles, and the time 7 hours and 15 minutes. After recharging, the return trip was made the same night in practically the same time. The vehicle was of the Jeantaud make.

**The Electrical Exposition at Como Destroyed by Fire.**—The buildings containing the electrical exhibition celebrating Volta's discovery of the electric pile were completely destroyed by fire on the morning of July 8th; cable messages report also that many scientific records and relics of Volta were lost. The exhibition was opened on May 15th and was to have remained open until October.

**The National Association of Municipal Electricians** will hold its next annual convention in Wilmington, Delaware, on Sept. 5th and 6th. In connection therewith there will be an electrical exhibition during the entire week. Papers will be read by Thos. Flood, Commissioner Wire Department, Boston; M. W. Mead, City Electrician, Pittsburgh; Capt. Wm. Brophy, Electrical Engineer, Wire Department, Boston, and other men well known in this line of work.

**Enormous Orders for Electric Automobiles.**—Mr. Isaac L. Rice, president of the Electric Storage Battery Company, is authority for the statement that orders have recently been placed for 4200 vehicles at an aggregate selling price of some $8,000,000. These consist of about 2000 pleasure vehicles, 2000 hansoms and broughams and 200 delivery wagons. The greater part of them will not be sold, but will be operated by the local sub-companies of the Columbia and Electric Vehicle Company.

**Westinghouse Electrical Apparatus to be Manufactured in England.**—It is rumored that the Westinghouse Electric Company, Ltd., an English corporation closely associated with the Westinghouse Electrical and Manufacturing Company, has acquired 100 acres of land close to Manchester, England, and will immediately erect works covering 40 acres, practically du-

Digitized by Google

plicating the Pittsburg plant. The works will be capable of employing 5000 hands. Lord Kelvin will be the electrical adviser of the company, and it is said the enterprise is backed by £1,500,000 of British capital.

**Control of the Stanley Company Changes Hands.**—It is stated on good authority that the control of the Stanley Electric Manufacturing Company, of Pittsfield, Mass., has passed into the hands of New York parties, and is for the present held by them as individuals, although it is understood that the sale means a consolidation with the Sprague Company. The price paid for the Stanley stock was $150 per share.

**Castings for the Single-Phase Rectifier.**—The design for a machine of this type prepared by Mr. J. C. Brocksmith and published in the June issue of the American Electrician has occasioned so many inquiries for laminae, castings and other parts that the editor of the American Electrician would be glad to have any one who has constructed this machine and is willing to supply these parts, quote prices for the same. For the benefit of readers who may desire to obtain such parts any offers will be published in these columns.

**A Canal Lift Controlled by Electric Motors.**—The large lift on the Dortmund and Ems Canal in Germany, capable of raising or lowering 600 ton barges, is controlled by electric motors. The lift is counterbalanced and operated by the addition of sufficient water to lower it, which is withdrawn when the lift is to be raised. The motion is governed by four enormous steel screws 81 ft. long by 11 ins. in diameter, which are rotated by electric motors. Other motors control the gates and drive the pumps.

**Electrical Research a Criminal Penalty.**—The following clipping from London "Lightning," exhibits a rare instance of the similarity of English and American slang, as well as what is still more rare, an international pun:

"From a storeroom of the London Electric Supply Corporation George Perrott took some copper. Then the order of things was reversed, and a copper took him. When the scene changed to the Greenwich Police Court, George was invited to spend 21 days in studying the conditions that exist in a dry cell of high internal resistance. He is now engaged in pursuing the suggested course of research."

**Electric Power in the Baltimore Tunnel.**—It appears that the information on which was based a note that appeared in the last issue of the American Electrician on this subject was erroneous. Electric locomotives are used for all eastbound freight trains, and all but a few passenger trains passing in the same direction, the crowded condition of the section rendering it necessary to run a few of the latter trains through under their own steam. Westbound trains run without the electric locomotives on account of the down grade. There is no delay in coupling or uncoupling, as the former is done in the Camden station, at one end of the tunnel while the passengers are getting on and off, and a flying cut-off is made at the other end.

**A Novelty in Cooling Machines.**—A new application of thermodynamics to domestic purposes has recently been developed in the shape of an air cooling apparatus for offices, apartments and habitations. It is a somewhat radical departure from previous methods in that the source of the cooling is not, as generally heretofore, the conversion of heat into mechanical work, but merely depends upon the latent heat of vaporization of water. Water from any convenient source is supplied in a thin film to the copper top of an air flue and a sharp air blast is directed axially along and over this flue from an electric fan. The forced evaporation chills the air flue vigorously and drops the temperature of the whole air blast from 10° to 20° F., according to the rate of evaporation attained.

**A Freight Barge Driven by Electric Motors.**—A firm of manufacturers near Birkenhead, England, has equipped one of its barges for carrying freight around the harbor of Liverpool with accumulators and motors instead of steam boilers and engines. The craft is 75 ft. long with a displacement, loaded, of 225 tons, its cargo consisting of 150 tons. The driving equipment consists of 112 storage cells, weighing 400 lbs., each with a capacity of 2000 ampere hours at a 7-hour discharge rate. The vessel is propelled by twin screws worked by two 40-h. p. motors. A small electric crane is also a part of the equipment. The advantage of the electric driving is said to be the increased cargo capacity and reduced risk of heating.

**The Electrical Manufacture of Caustic Soda and Bleaching Powder at Niagara Falls.**—A new plant for the electrolytic decomposition of sodium chloride or common salt is now being built at Niagara Falls by the Acker Process Company. The works will utilize 3000 electrical horsepower, to be delivered in the form of 8000 amperes of direct current at 300 volts pressure, to be generated by the Niagara Falls Hydraulic Power and Manufacturing Company. These 8000 amperes will pass through a single series of decomposers, the great peculiarity of which is the fact that the salt is dry and molten instead of in solution. This condition increases greatly its conductivity and is said to improve in some ways the output. The high temperature will be maintained by the $C^2R$ losses.

**Electric Traction on the New York Elevated.**—At the meeting of the Manhattan Railway Company, held on July 11, it was decided to place a contract with the E. P. Allis Company, Milwaukee, for eight 8000-h. p. engines capable on overloads of developing 100,000 h. p. The company had already selected a location for a power house and placed a heavy order for third rails. These engines will be by far the largest ever used for driving electrical generators, having just double the capacity of the eleven 4000 h. p. sets now under erection for the Metropolitan Street Railway Company, New York City. The power station of the elevated will have exactly the same capacity as that planned for the Third Avenue Railroad of New York City, for which sixteen 4000 h. p. units were proposed.

**Telephones on Street Cars.**—The new motor cars which are to be used on the suburban line between St. Paul and Stillwater will be equipped with a system of telephonic communication with the main office. As the new road is a cross country line, there will be miles of open country between stations. In case of accident when the cars are out in the country, it is important that the motorman should be able to communicate quickly with the home office. For that purpose each car is supplied with a telephone placed in the front vestibule. The telephones are supported by springs, so the jolting of the car will not jar the instruments. At the feed poles, which are placed a quarter of a mile apart, the motorman can "plug" in his telephone and open communication with the head office. In case a car is disabled or snowed in, the office can be advised and relief dispatched.

**The Prevention of Gas Explosions at Cut-outs and Switches.**—A simple and ingenious means has been adopted in the Cleveland intake tunnel to prevent the ignition of any explosive mixture that may occur at the electrical fuses or switches. The tunnel is being built to supply Cleveland with water from a crib situated 26,000 ft. from the shore. Two explosions occurred in the running of the first drift, costing several lives. It was claimed that the gases were ignited from the electric lighting fixtures. When the work was resumed at the point where the gas belt was touched, branches were led from the supply pipes of the compressed air system to the cabinets containing the switches and cut outs. A current of fresh air was constantly introduced into these cabinets, in this manner keeping the gases from accumulating therein, so that when fuses blew or the switches were opened there was no danger of explosion.

**The Convention of the Independent Telephone Association.**—The annual meeting of the Independent Telephone Association at Chicago on June 26th, 27th and 28th gave further proof of the stable character and growing importance of the independent telephone interests. The attendance was large, amounting to some 250, and of a character which must have favorably impressed the representatives of capital who are beginning to interest themselves in this field of such

Digitized by Google

great apparent promise. The papers presented departed in character from those of previous years by taking up broad questions of policy and general problems of construction, rather than the struggles of local companies against the Bell interests. The association of the independent companies has developed a power of no mean proportion when compared even with that of the Bell companies themselves. The number of independent exchanges was given at the convention as 2500, serving some 300,000 subscribers, with a total investment of over $50,000,000.

---

**The Rule Against Automobiles in Chicago Parks Declared Void.**—Judge Gibbons of the Circuit Court of Cook County has decided that the rule of the South Park Commissioners of Chicago barring automobiles from the parks and boulevards of the city is void. The decision was rendered in the case of an engineer of the American Electric Vehicle Company who ran an automobile on Jackson Boulevard to bring a test case. The opinion is based on the unreasonable nature of the ordinance "when, as a matter of common observation and scientific knowledge, there is less danger in propelling an automobile than there is in driving a horse and buggy." The opinion further states "the time is not far distant when no horse car, trolley car or cable car will be permitted to occupy any of our business streets; they have served their purpose, they should be either above or below the surface of our streets." Judge Gibbons certainly shows an iconoclastic spirit.

---

**The Dangers of the Third Rail.**—Remarkably few accidents have been recorded on the various railway installations in this country, notably those of the New York, New Haven & Hartford, Brooklyn Bridge and the elevated roads in Chicago. Accounts occasionally come from the former of the cremation of a stray dog in stepping from the third rail to one of the service rails or the disappearance of a steel rod umbrella dropped across the tracks. Track repairmen on these lines have found them less dangerous than might be expected, frequently allowing themselves to get shocks which prove of no consequence. This is undoubtedly due to the fact that currents obtained enter or leave the body as a rule through the feet, and the stockings worn, when dry at least, serve as a fair insulator against street railway voltages. An instance where this protection was not afforded and where the danger immediately became evident is recorded in Chicago, where, on June 30th, a small bare-footed boy climbed on to the structure of the Metropolitan Elevated, stepped from the third rail to one of the others and was electrocuted instantly.

---

**The Municipalization of the Detroit Street Railways Stopped.**—The proposed plan of Gov. Pingree and others for the municipal ownership of the street railway system of Detroit has received two serious checks. The ordinances brought before the Common Council were laid on the table on June 27th and the State Supreme Court on July 5th stated that the law authorizing the appointment of the street railway commission is unconstitutional. An attempt was made to get around this Supreme Court decision and dispose of the valuable plants which the Citizens' Traction Company now owns and will have on its hands at the coming expiration of the franchises, by forming a new company, known as the Detroit Municipal Railway Company, and putting through the local Council a "security franchise," designed to secure the bonds with which the new company proposes purchasing the existing railway systems. The security franchise provided for six-for-a-quarter fares practically for 48 years. This franchise was vetoed by the Mayor and failed to pass the Council over the veto. Mr. T. L. Johnson then sent a communication to Gov. Pingree, indicating his purpose of abolishing tickets and transfers and endeavoring to make the most money possible out of the property during the remainder of the franchise term.

---

**Electric Street Railways for London.**—One of the last of the world's great cities to adopt electric traction is the greatest of all, London. The prejudice against the trolley car is, however, dying out and the electrical equipment of a large portion of the London United Tramways has recently been commenced. When completed, this will comprise 40 miles of electric lines, operating some 250 motor cars. The distribution of current is peculiar. A double trolley will be used, as the company has been debarred from using a ground return. The double trolley will be arranged on the three-wire system, the two inner trolley wires of the double track line being connected together and forming the neutral, the two outer trolley wires forming the positive and negative, respectively. The neutral will be grounded at the power station only, to prevent any possibility of a ground return. The outer conductors will be divided into half mile sections fed by independent feeders from the power station, the neutral being similarly arranged in sections three times as long. One part of the line will be operated from a sub-station equipped with transformers and rotary converters, supplied with power at 5000 volts, three-phase, 25 cycle. Two rotary converters, one for the positive and the other for the negative side of the system will be mechanically coupled to each other for balancing the load.

---

**An Extensive Theft of Electric Current.**—The Chicago Edison Company has arrested the engineer of an office building in the business section of Chicago on the charge of stealing some $5000 worth of power from the company's underground lines. It would appear from the press accounts that he was accused of having used a break-down connection for some three years' time, drawing some $5 worth of power every night. An interesting story of the detection of the theft is told as follows in one of the Chicago papers: A month ago the Edison Company became aware that its lines were tapped somewhere in Dearborn Street between Van Buren and Harrison streets. The case was put into the hands of a detective agency. The detectives made a tour of all the office buildings along Dearborn Street in the guise of fruit peddlers. Their suspicion at last fell upon the engineer of the building at 327 and 329 Dearborn Street. By telling the engineer a "hard luck" story one of the detectives, with his basket of fruit, was allowed to stay for several hours one rainy night in the shelter of the engine room. While there he saw the engineer go under the sidewalk and throw an electric switch. The dynamo in the building was then turned off, but 65 lamps still gave forth their usual light. The detective found that the dynamo was stopped every night between midnight and 6 o'clock.

---

**Novelties in Transmission Line Construction.**—The 31-mile line of the Kootenay-Rossland Transmission Company in British Columbia consists of two parallel and duplicate pole lines, on one of which the cross arms are roofed over to prevent the wet snow from piling up on the cross arms around the insulators, which it does to a height of some 18 to 24 ins. during seasons when there is no wind. The cross arms are two in number, the upper one some 8 ft. in length with 4 pins, and the lower shorter, holding two pins. The upper one is covered with a cedar roofing 24 ins. wide, sloping slightly downwardly from the pole each way toward the ends of the cross arm. The lower, immediately below it, is roofed to a width of 16 ins. During the past winter service was continued over both lines, even when the exposed line had from 10 to 12 ins. of snow on the cross arms. If any leakage existed it was impossible to detect it, so that the roof appears to be quite an unnecessary precaution. Another peculiarity of the same line is the crossing of the Columbia River, which is in a single span 1500 ft. in length. The wires are No. 000 bimetallic, maintaining a conductivity equal to that of the balance of the line, which is No. 0 copper. These spans are unsupported by strain cables, the total sag being some 52 ft. with the strain taken up by a number of ordinary porcelain insulators in a strain tower at each end of the crossing. The interaxial distance betwen the wires is only 6 ft., but no trouble has been experienced from swinging crosses or from breakage due to wet snow, which has at times adhered to the lines to a diameter of about 4 ins. These facts are taken from an illustrated description of the system published with the usual clearness and thoroughness of illustration characteristic of the "Journal of Electricity."

### The Handling of Railway Car Controllers.

Frequently the general manager of a street railway sytem, learning that an electric car requires only half as much current to drive it on the series notch as it does on the parallel notch, instructs his motormen to use the series notch to the exclusion of the other on heavy grades and slow schedules. While the use of the controller notch, which puts the motors in series with no resistance in the circuit, is far preferable to that of any notch inserting dead resistance, yet a little consideration will show that the use of the highest speed, or parallel notch, is preferable in more cases than would be imagined at first thought.

---

Taking the case of heavy up grades the torque or draw-bar pull required to move the car at a uniform speed is approximately the same, whether that speed is high or low. To render the argument more clear, let us assume a definite case of a grade such that each motor must deliver a torque requiring 40 amperes. If the car is run up this grade with the controller on the series notch all the current taken by the car passes through both motors and the total demand from the line is only 40 amperes. If the car is run on a parallel notch 80 amperes will be taken from the line, 40 going to each motor, but in the former case the car will run only half as fast, or in fact somewhat less than half as fast, since the ohmic drop in the motor circuit is twice as great when the motors are in series as it is when the motors are in parallel. Thus the car will require somewhat over twice as long to climb a given grade, and, since the current in each motor is 40 amperes in either case, the total amount of energy wasted in $C^2R$ losses, which heat up the motors, will be over twice as great for a given climb if the series position of the controller is used. Another explanation of the same action is the fact that when working in series the motors are run at a much slower speed and hence at a much lower efficiency. This heating of the motors in case a route has many heavy grades may prove a serious factor, burning out many car equipments unless particular instructions are given to use the full speed position as much as possible in order to get up hills at the highest permissible speed. The same argument applies to running at a uniform speed on a level. In covering a given route about twice as much heat will be generated in the motors if they are run in series as if they are run in parallel. Electric locomotives and other slow running cars, swing bridges, or other pieces of apparatus, are often fitted with two or four motors, run frequently two in series. If these motors were geared with twice as great a reduction they could be run in parallel and would do twice as much work with practically the same heating.

---

Another case arises, however, in which the series connection of the motors is advisable, and for which special instructions to motormen may prevent serious trouble, and that is the case where the demand upon the distribution system or any particular feeder becomes so great as to cause an excessive drop between the power house and the cars. Instances of this kind frequently occur on suburban lines, reaching parks, summer resorts or beaches, with heavy loads of such infrequent occurrence that the use of much copper for feeding them is unwarranted. If a large number of cars start running about the same time on such a line distant from the power station—as often occurs after the closing of an entertainment—the excessive demand for current may cause a drop of several hundred volts in the line, so that even if the circuit breakers are held in at the station the cars get hardly pressure enough to crawl along and not enough if heavy grades are encountered. If, under these circumstances, the motormen are instructed to run on the series notch each car will require only half as much current, and the drop in the line will be so much less that the cars will make practically the same speed as though they were running on the parallel notch with a lower voltage. The current required for running the cars over the route will thus be reduced 50 per cent.

---

For ordinary running with frequent stops both calculation and experiment have shown that the greatest economy of power is obtained by starting the cars as rapidly as possible, advancing the controller notch to the full speed position as soon after starting as the capacity of the motors and the comfort of the passengers will permit, and turning off the power completely as soon as conformity with the schedule will permit, allowing the car to drift as long before the brakes are applied for the next stop as possible. This is due to the fact that a large part of the power given to electric cars is required to accelerate them and is afterwards thrown away as heat at the brake shoes. If the car is allowed to slow down by drifting, considerable of this energy absorbed in acceleration is afterwards utilized in overcoming legitimate frictional resistance of running and is not wasted in braking. In order to make schedule time with so much drifting rapid acceleration is necessary. It will be found by trial that this method of running cars will show a far smaller consumption in kilowatt hours per car mile than slow and gradual acceleration up to maximum speed and braking from that speed down to the next stop.

**Unitooth Alternators.**

Probably the first impression of the reader familiar with alternating current machinery on noticing the views of the station of the Louisville Electric Light Company, on pages 367 and 371 in this issue of the American Electrician, will be one of surprise at the great length of the field magnets. While these machines are only a few years old and, in fact, of a class—direct coupled alternators—still somewhat rare in American central stations, they represent a practice already obsolete in the construction of large dynamos, and that is the use of unitooth or pole-wound armatures. In the machines referred to the armature coils are wound on poles—equal in number to those of the field—which poles have a length, indicated by the protecting rim attached to the fly wheel, almost as great as the length of the field poles of more modern machines. In fact, the armature of one of these machines could probably be used very satisfactorily as the field of a revolving field machine if the original stationary field were removed and replaced by a modern stationary armature with distributed windings.

---

The great reduction of the weight which would follow such a change indicates the advance in alternator design which has been made within the last few years. This advance is due largely to the distribution of the armature winding in a large number of slots per pole, very much like the winding of a direct current machine. By this means the self-induction of the armature is greatly reduced, as is the reluctance of the magnetic circuit, both factors reducing the necessary ampere turns for field excitation, and thereby reducing the length of the field magnets required to hold exciting coils of sufficient power. Incidentally the improvement reduces the losses of the machine and gives a better wave form to the alternating current delivered.

---

**Feed Water Heaters vs. Economizers.**

In the present state of the art of power production by steam the managers of but few installations of any size—and especially is this true of central stations—are so short-sighted as to get along without one or the other of these devices for restoring heat which otherwise is wasted at one or the other of two stages in the making of the final product, power. Some few small plants, where the cost of fuel is very low, or where an annual saving of from $25 to $100 is not considered sufficient incentive for an initial investment of $200, continue to work without them, the chief excuse being the ease and simplicity of feeding the boilers by means of injectors, which, of course, cannot be used for feeding hot water.

---

As a general rule, both an economizer and a feed water heater are not considered necessary, as either one alone will raise the temperature of the entering water a good ways toward that of the steam within the boiler. The determination of which should be used in any case depends largely on local conditions, a few of which are outlined below. If the exhaust steam is entirely used for any other purpose, such as heating, as it is in most isolated plants a good part of the year, an economizer should be used for heating the feed water. If the plant is non-condensing and the exhaust steam is not used for heating purposes, but is simply thrown away, the feed water heater would seem to be preferable for several reasons which are pointed out in a letter on the subject which appears on other pages of this issue. Among these reasons are the lower initial cost, and, as a rule, the lower cost of maintenance, as the economizer requires running machinery to scrape the soot from its tubes. It should be noted, however, that an exhaust steam heater cannot, under any conditions, raise the temperature of the feed water above 212° F., while an economizer may, if its heating surface is sufficient, raise it to boiler temperature; about 350° F., if the pressure is about 125 lbs. In fact, with a wasteful boiler some steam may be generated in the economizer before the feed enters the boiler. On this account economizers must always be run under boiler pressure, while feed water heaters of the open type may be used, or of the closed or surface type may be run under atmospheric pressure on both sides of the heating surface, the water being pumped hot in either case.

---

In case of a condensing plant there are two alternatives. One of these is the use of economizers for heating the feed water and the application throughout the equipment of mechanically or electrically driven pumps and other auxiliary applications of small powers about the plant. Steam driven auxiliaries are extremely wasteful of steam and should never be used where their exhaust steam is thrown away, as it is in plants with economizers. They are, however, much more easily controlled and varied in speed than are auxiliaries mechanically or electrically operated, and obtaining, therefore, the high steam economy of the main engines. This ease of control and the loss of draft consequent upon the use of economizers, which loss of draft necessitates either mechanical draft or a higher chimney, induces many central station engineers to favor steam auxiliaries exhausting into feed water heaters, which return their waste, in place of economizers and electrical auxiliaries.

---

If jet condensers are used and the initial source of the boiler feed is stone cold, the exhaust of the auxiliaries, wasteful as they are, will hardly be found sufficient to raise the feed to 200 degrees or more. Under these conditions it is becoming customary to use closed or surface primary heaters for transferring some of the heat of the engine exhaust to the cold feed water, which is afterward passed through secondary heaters, taking the exhaust of the auxiliaries for further raising the temperature of the feed. The primary heaters cannot be expected to do very much since the exhaust steam passing through them is under vacuo and its temperature is only from 125 to 150 degrees F., according to the perfection of the vacuum. Enough heat, however, can be saved to warrant the expense of such primary heaters, and they assist in the condensation of the exhaust. The temperature of the feed may be raised in the primary to 100 degrees or somewhat more and in the secondary heaters, taking exhaust steam at atmospheric pressure, to 200 degrees. The secondary heaters are often fitted with a live steam supply to reinforce the heat saved from the engine and auxiliary exhausts. While the use of live steam for feed water heaters may seem like lifting one's self up by one's boot straps, experiment has shown that there is, for some reason, an economy in its practice, provided there is no other means for heating the feed water up to about boiling point.

---

Where surface condensers are used and the condensed water is returned for boiler feeding, primary heaters are of no value, since the temperature of the hot well is practically as high as any that can be obtained by passing the feed through such a heater. As a rule, however, the difficulties of separating oil from the exhaust steam or feed water make a supply of fresh water from an outside source preferable, unless its cost is excessive or its chemical character so bad as to render its purification a matter of difficulty.

## CONSTRUCTION OF THE SINE CURVE.

BY GEORGE T. HANCHETT.

For accurate testing and similar work involving alternating currents, it is frequently very desirable and is sometimes indispensable to have a source of e.m.f., which accurately follows the sine law. Typical of these cases are the calibration of instruments, the use of secohmmeters in connection with a Wheatstone bridge, and many other cases which might be mentioned where a true sine e.m.f. is indispensable for accurate work. Indeed, a current having this property is so highly desirable that numerous attempts have been made to build a small dynamo with the pole pieces so shaped as to cause the machine to generate an e.m.f. of the desired wave form.

In such devices as these efficiency is not a consideration, and accuracy is everything. Simplicity is also desirable. In the following paragraphs the writer ventures to call attention to some devices which will produce an accurate sine e.m.f., and some of which, so far as he is aware, are original.

A simple rectangular coil, suitably mounted on an axis which is placed at right angles to the earth's field of force, will, if rapidly rotated, produce a true sine e.m.f., provided that the current drawn from it be not so great as to react on the earth's field and destroy its uniformity. A device of this kind is shown in Fig. 1. A brass spider which may be conveniently made from a single casting is provided. The wire is tightly wound on this frame and the ends are brought down to two collecting rings on which suitable brushes are made to bear and from which the experimental current may be drawn. It is not difficult to see that a drum armature, which is a succession of such rectangular coils, may be provided with two collecting rings at equally distant points on the winding and similarly placed in the earth's field and rotated, thereby producing an e.m.f. of the desired character; and indeed this is true of any bipolor armature. The objection to these devices is the high speed at which they must be driven in order to obtain commercial frequencies, for the earth's field is essentially a bipolar one. The armature will give one complete cycle at every revolution, and if a frequency of 8,000 cycles per minute is desired, 8,000 revolutions per minute must be made, which is a dangerous speed for any armature. Moreover, the irregular shape of overwound drum armatures and the complication of iron in the circuits arranged with other purposes than this in view, and the distorting effect of eddy currents, render this device rather unsatisfactory and more of an expedient than good practice.

The rectangular form shown in the figure is perhaps better than the use of an armature for the reason that it can be constructed simply and accurately and in such a manner that it is not likely to fly apart. Unfortunately, only very minute currents can be drawn from these coils, or the earth's field will be distorted and with it the sine e.m.f.

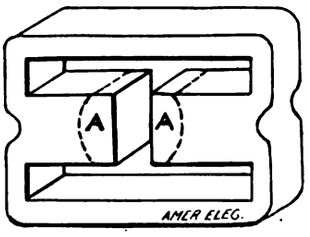

FIG. 2.—DEVICE FOR PRODUCING AN ACCURATE SINE E. M. F.

A more suitable field can be provided for the purpose of such experimentation as this by means of a very heavy magnet, with two opposite and parallel poles. These poles should be very large in proportion to the armature for which they provide a field. The edges should be rounded slightly, for the flux of force tends to concentrate, there. A small loop, or, better still, a little drum armature wound on a wooden core, may be revolved in such a field as this, and will give a sine e.m.f. Considerably more current can be drawn from this device than from one in which the earth's field is used. An old dynamo frame of the form shown in Fig 2 will make an excellent field for such a purpose as this, if the polar recesses are suitably filled with semi-cylindrical blocks, A A. One of the horse shoe type will not be satisfactory, for the flux will concentrate on the edges which are next to the winding.

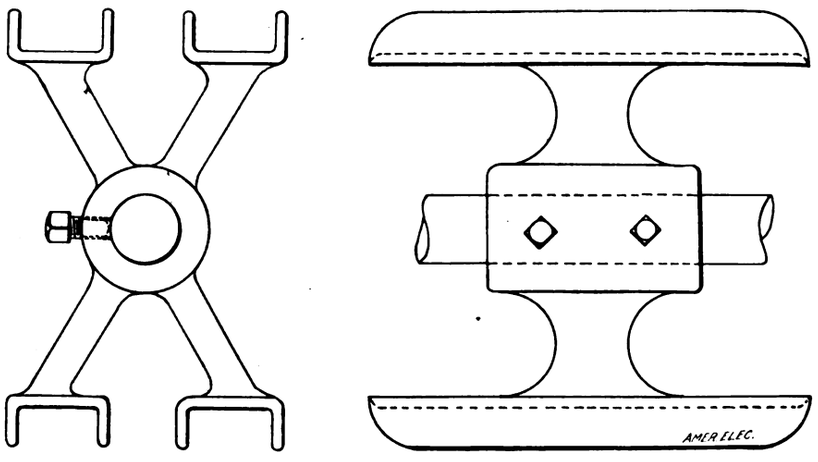

FIG. 1.—DEVICE FOR PRODUCING AN ACCURATE SINE E. M. F.

Another ingenious method is shown in

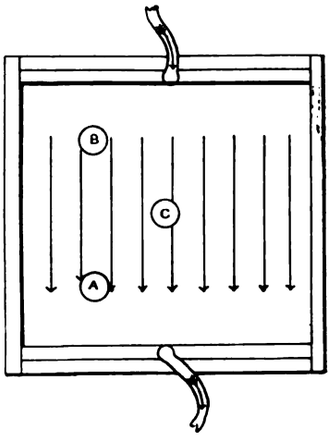

FIG. 3.—DEVICE FOR PRODUCING AN ACCURATE SINE E. M. F.

Fig. 3, but unfortunately is not practicable for anything but very low frequencies. A rectangular tank is provided, in the center of which is immersed an electrode, C, of metal or carbon as may be convenient. Another electrode, A, is also immersed in the tank, and by use of suitable machinery is made to travel about the first in a true circle, being driven by a suitable motor at constant speed. On opposite sides the tank is lined with plates, and current passes from one plate to the other as shown by the arrows. It distributes itself uniformly, the lines of flow from plate to plate being straight lines and normal thereto. If these conditions obtain, it will be seen at once that the various points of potential through which the moving electrode passes vary in their differences from the potential of the stationary electrode according to the sine law. It is obvious that these devices can be rotated only very slowly. If we place in the tank another moving electrode, B, 90 degrees in advance of the first, we may draw two-phased currents from the two electrodes, using the middle as a common return; and with three electrodes at 120 degrees apart, we may draw three-phased currents, all of which will be practically in sine curves.

In Fig. 4 is shown a device which should give a sine curve of great accuracy and which can be driven at speeds corresponding to some of the lower frequencies. A straight conductor is provided, and it is essential that this should be of uniform resistance and that the total resistance should be as high as possible. The conductor should be more or less substantial, as it has to stand the friction of a traveling brush and should partake of the nature of a rod or bar. The ends of this rod are connected to two or more storage batteries in series, care being taken that the number of storage batteries be even. It is important that these storage batteries should be as much alike in every respect as it is possible to make them, for their e.m.f. should be of the

Digitized by Google

same magnitude and their internal resistance should also be the same. They must, therefore, be charged together and, in general, subjected to the same treatment at all times.

Upon the rod which is thus supplied with current travels a small collecting brush, which is driven by the well-known crank disc and plate in a simple harmonic motion. A lead is brought out at the middle connection of the batteries and another is connected to the traveling brush. When

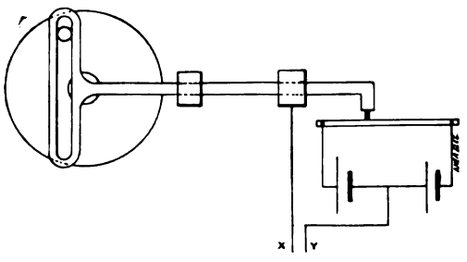

FIG. 4.—DEVICE FOR PRODUCING AN ACCURATE SINE E. M. F.

the machinery is set in motion there will exist between these two points or leads an e.m.f. which will closely follow the sine law. It will be readily seen that if the distribution of potential along the wire is uniform, varying directly as the length, and if the motion of the brush is harmonic, the potential varies in the same way. The machine should be carefully set so that the maximum rate of change of brush position shall correspond with the position of zero potential on the rod. To accomplish this, the crank disc should be set so that the pin is on a vertical line, and the brush should be adjusted along the driving rod until the potential between the terminals X and Y is zero.

Still another device which is somewhat similar in its construction and principle is shown in Fig. 5. Two circles are provided which are tangent to each other, but insulated from each other at the point of tangency. Circles may be cut from the ends of brass tubes of suitable diameter and mounted on a board. Over the face of this circle is rotated a current-carrying wire stretched in a frame. The centre of rotation of this wire corresponds to the point of tangency, and as at this place there is insulation, the wire touches the circles only on the outer contacts, even though it be in a secant position. Connections are made to the two brass circles, and between them an alternating sine e.m.f. exists. In this device and also in the device shown in Fig. 4 it is necessary to avoid drawing too much current from the circuit for the reason that unbalancing will occur in the wire over which the moving contact is made. To further reduce this error, the current in the stretched wire or rod should be very large, so large that the currents that will be necessary to use in the experimental circuit will be a very small percentage thereof.

Another device which is similar to that shown in Fig. 4, but which can be driven at higher speed, is easily constructed. In this arrangement the traveling brush is mounted on a parallel rod between two wheels which are driven at the same speed in the same direction. The brush so mounted partakes of an up and down motion as well as a lateral one, but neither of the motions interferes with the harmonic motion of the other. The brush makes contact with a current-carrying bar or wire. It must be of suitable form, so that the lateral motion will not interfere with its contact on the wire. The advantage of this apparatus arises from the fact that it can be driven at a much higher speed than the apparatus shown in Fig. 4, for the connecting rod can be balanced. The electrical connections are the same.

## A GIFT TO THE STEVENS INSTITUTE.

Andrew Carnegie has promised to give $50,000 to the Stevens Institute of Technology for a new engineering laboratory. Plans for the new building will be prepared at once. When completed the laboratory, it is expected, will surpass those of Cornell and Columbia and will equal that of the Massachusetts Institute of Technology, which is said to be the best in the country.

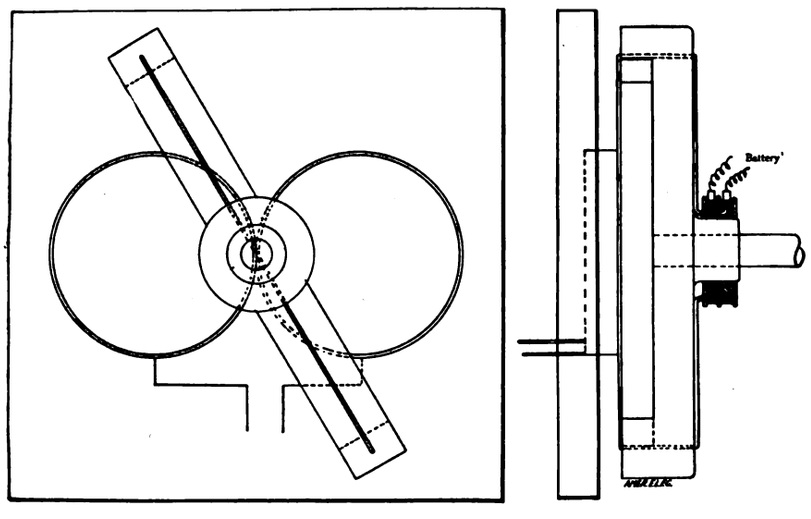

FIG. 5—DEVICE FOR PRODUCING AN ACCURATE SINE E. M. F.

## AMERICAN TELEPHONE PRACTICE.

### TESTING.*

BY KEMPSTER B. MILLER.

A very important measurement, especially in telephone cables, is the determination of the capacity of the line conductors with respect to all neighboring conductors. The usual method of making capacity tests is to note the deflection produced when a condenser of known capacity, after having been charged to a known potential, is discharged suddenly through the galvanometer, and to compare this

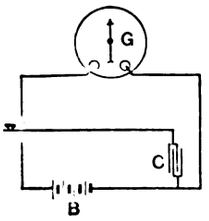

FIG. 1.—CAPACITY TEST.

with the deflection obtained when the cable or conductor being measured, after being charged to the same potential, is discharged through the galvanometer. The deflections produced under these circumstances are proportional to the charges, and therefore to the capacities of the standard condenser and the line or cable. The circuits for obtaining the deflection produced by the discharge of the condenser are shown in Fig. 1, where C is the standard condenser, B the battery, and G the galvanometer. When the key is depressed the condenser is charged to the full potential of the battery, B. The key is then suddenly released, thus allowing the charge from the condenser to pass through the galvanometer, thus producing a certain throw of the needle. The connections are then made as shown in Fig. 2, the same battery, B being used. When the key is depressed the cable is charged, and when suddenly released this charge flows through the galvanometer and produces another throw of the needle. By comparing the throw produced by the charge of the condenser with that produced by the charge of the cable, a direct comparison may be made between the capacity of the cable and that of the condenser. Thus, if with the 1/999 shunt the discharge from the condenser gave a deflection of 100 scale divisions the capacity of the condenser be-

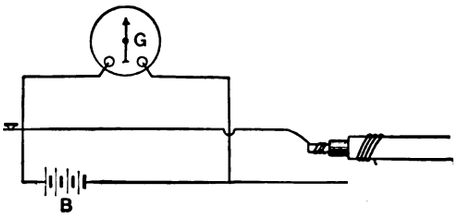

FIG. 2.—CAPACITY TEST.

* From a book to be published by the American Electrician Company.

Digitized by Google

ing 1/10 microfarad, and if with the same shunt the discharge of the cable produced a deflection twice as great, we would know that the capacity of the cable was

$$2 \times \frac{1}{10} = \frac{1}{5} \text{ microfarad.}$$

Convenient connections for making capacity tests are shown in Fig. 3, where G is the galvanometer, S the shunt, C the standard condenser, KK discharge keys, V the selecting switch, and, B a battery of eight or ten cells. With the switch,

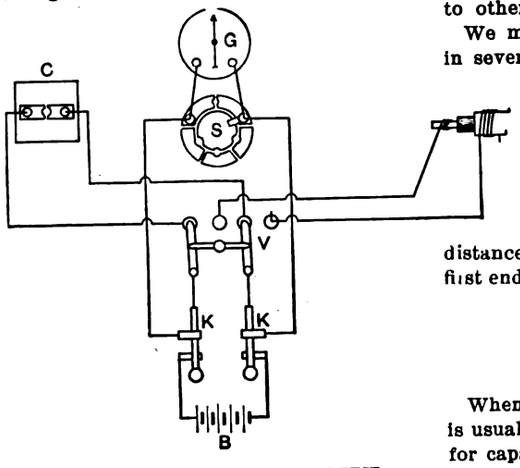

FIG. 3.—CIRCUITS FOR CAPACITY TEST.

V, at the left and both discharge keys depressed, the current from the battery will flow into the condenser, thus charging it. Upon the sudden release of the discharge keys, the condenser will discharge through the galvanometer and shunt, giving a deflection which should be noted. With the switch, V, at the right, the cable may be charged and discharged in the same manner, and the deflection produced by its discharge noted. About seven cells of battery are usually sufficient for making capacity tests on telephone cables. If a non-adjustable condenser only is available, one having a capacity of 1/10 microfarad is probably most desirable. For accurate work a subdivided condenser, having its divisions so arranged as to be easily connected in multiple or in series, or in combinations of the two, is very desirable. Then the condenser capacity may be varied until the throw from the condenser is nearly equal to that from the cable, thus greatly minimizing the liability to error in the results. In making capacity tests the wire under test should be carefully insulated and all the other wires in the cable should be connected together and to the sheath or ground. Fifteen seconds should always be allowed for the charging of the cable.

If d′ is the throw due to the discharge of the condenser, d that to the discharge of the cable, K the capacity of the condenser in microfarads, and X the capacity of the wire being measured, then

$$X : K :: d' : d$$

$$X = \frac{d'}{d} K.$$

If the throws of the galvanometer are too large to be measured, the shunt must be used. In this case d or d′ in the formula will be the actual throws observed multiplied by the multiplying power of the shunt.

### THE LOCATION OF FAULTS.

When a break occurs in a wire in a line or cable, the ends remaining insulated from other wires and the ground, the only recourse is to capacity tests. The capacity of the two parts of the wire will be proportional to their lengths, the wire being uniform in size and in its relation to other wires, throughout its length.

We may locate a break of this nature in several ways.

Measure the capacity of one end of the broken wire, then go to the other end of the cable and do the same. Calling D the length of the cable in feet, C the capacity of the first portion of the wire, C′ that of the other and X the distance in feet to the break from the first end, then:

$$X : D :: C : C + C'$$

$$\text{and } X = \frac{CD}{C + C'}.$$

When a good wire is available, and this is usually the case, set up the instruments for capacity testing, and take a throw, d, on the broken wire, another, d′, on the good wire, and a third, d″, on the good wire with the broken wire connected to it at the far end.

Evidently the throw on the whole broken wire would be $d'' - d' + d$.

Hence where D and X have the same significance as before

$$X : D :: d : d'' - d' + d$$

$$\text{and } X = \frac{dD}{d'' - d' + d}.$$

The location of breaks is much complicated by the presence of poor insulation between ruptured portions, and between other wires. The insulation resistances between these parts should always be taken. If less than one megohm, the results obtained by the capacity tests should not be relied on, and other methods too complex for description here should be resorted to.

The location of crosses or grounds is rendered somewhat difficult by the fact that there is nearly always some resistance in the fault itself. If we know the resistance of the defective wire and have no good wire running parallel with it we may proceed as follows, using a good Wheatstone bridge:

Measure the resistance of one end of the defective wire through the fault to ground. Do the same at the other end. Then calling R the total resistance of the wire (either known or calculated from its size and length), R′ the measured resistance from the first end, R″ that from the other end, X the resistance from the first end to the fault, Y the resistance from the second end to the fault, and Z the resistance of the fault, we have:

$$R = X + Y$$
$$R' = X + Z$$
$$R'' = Y + Z$$

Solving these for X and Y we have

$$X = \frac{R + R' - R''}{2}$$

$$Y = \frac{R - R' + R''}{2}$$

which values are independent of the resistance of the fault. Knowing the resistance to the fault, it is easy to compute the distance to it, from the resistance per foot of the conductor.

When a good wire is available, the Varley loop test should be used, as it is more accurate than the method just described. For this a Wheatstone bridge is used, and connected as in Fig. 4. The good and bad wires are joined at their distant ends, and one terminal of the battery connected to the point, e, on the bridge, while the other terminal is grounded.

The rheostat arm now includes the resistance, R, plus the resistance of the bad wire to the fault, while the unknown arm includes the resistance of the good wire, plus the resistance of the bad wire on the other side of the fault.

The equation of the bridge, when balanced, then becomes

$$\frac{A}{B} = \frac{R + X}{C + Y}$$

where R is the unplugged resistance of the rheostat, X the resistance to the fault, Y the resistance beyond the fault, and C that of the good wire.

Now calling K the resistance of the loop consisting of the good and bad wires, we have

$$K = X + Y + C$$
$$\text{or } C + Y = K - X$$

Substituting this in the second member of the equation of the bridge, we have

$$\frac{A}{B} = \frac{R + X}{K - X}$$

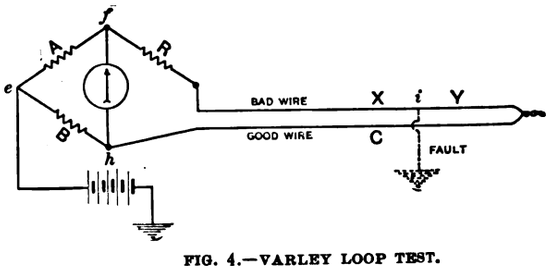

FIG. 4.—VARLEY LOOP TEST.

$$\text{whence } X = \frac{AK - BR}{A + B}$$

which is independent of the resistance of the fault, and of the resistance of the good wire.

Sometimes, in ordinary paper cables, the requirement is made that a rubber-covered test wire shall be run through the center of the cable, so that at least one good wire may be available in testing.

## SAFETY VALVES.

Probably some of the young engineers of the present day, advanced as they are in the science of steam engineering, never saw one of the appliances here illustrated by Fig. 1 and termed a "Lever Safety Valve." However, it is but a comparatively few years since no other arrangement was known for the relief of steam boilers when the pressure became too high.

For years boiler tenders and firemen wrestled with sticking safety valves which would not open until they got good and ready and the pressure had risen far above the supposed blow-off point. But once a-blowing, the lever valve made up for its lateness in starting, for it would operate until the pressure in the boiler had fallen far below the normal.

Then this type of valve had a very ugly fashion of occasionally sticking fast to its seat, and in extreme cases the disc has been found so fastened to the seat that it was with difficulty broken away with a hammer. These valves are still in use in antiquated plants, and are manufactured because there is a limited demand for them for the reason that they are cheaper than the improved spring pop valve, three types of which are shown by Fig. 2, as manufactured by the Crane Company, Chicago, Illinois. This company is also the manufacturer of the lever type of valve as shown by Fig. 1. These valves used to be made by about every foundry or machine shop that could sell one of them, but few are made now-a-days for use on steam boilers.

Fig. 2 shows three types of "pop" safety valves, the "Standard" being shown with and without side outlet. The straight lever type is also represented and the details of construction may be readily inspected from the three views given. In adjusting these valves the springs are of such strength that one-sixth turn of the nut will change the pressure approximately five pounds either way. As the valves are self-adjusting, they require no changing after once having been set at the required pressure. The valve seats are bevelled at an angle of 45 degrees to the center line of axis and the lever is arranged to lift the valve off its seat to the extent of one-eighth the diameter of the valve opening in accordance with the rules and regulations of the United States Board of Supervising Inspectors of Steam Vessels.

Probably all the present styles of pop valves, as well as balanced valves for steam distribution, are based upon Richardson's original creation of nearly half a century ago. Foremost in the list of improvements upon Richardson's crude yet effective invention, may be placed the Crosby and Ashton valves. The Crosby, as illustrated by Fig. 3, is the original of encased locomotive pop valves employing a relief lever for convenience of relieving the pressure in the boiler. This valve can be changed to a higher or lower pressure without removing the valve or reducing the pressure in the boiler.

In the Crosby type, as shown by Fig. 3, the valve proper, B, acts upon two flat annular seats, V, V, and W, W, and is held down against steam pressure by the spiral spring S. The area contained between the seats W and V is what the steam pressure ordinarily acts upon to overcome the resistance of the spring. The area contained within the smaller seat WW, is not acted upon until the valve opens.

The larger seat, V V, is formed on the upper edge of the shell or body of the valve, A. The smaller seat, W W, is formed on the upper edge of a chamber or well, C C, which is situated in the center of the body of the valve and is held in place by the arms, D D, which connect it with the body of the shell. These arms have passages, E E, for the escape of steam from the well when the valve is open. This well is deepened so as to allow the rings, X X, of the valve proper to project down into it far enough to act as guides. The flange modifies the size of passages, E E, and turns upward the issuing steam.

When the pressure under the valve is within about one pound of the maximum pressure required, the valve opens slightly and the steam escapes through the outer seat into the cylinder and thence into the air; the steam also enters through the inner seat of the well, and thence through the passages in the arms to the air. When the pressure in the boiler attains the maximum point the valve rises higher and steam is admitted into the well faster than it can escape through the passages in the arms, and its pressure rapidly accumulates under the inner seat; this pressure thus acting upon an additional area, overcomes the increasing resistance of the spring and forces the valve wide open, thereby quickly relieving the boiler.

When the pressure within the boiler is lessened the flow of steam into the well is also lessened, and the pressure therein diminishing, the valve gradually settles down; this action continues until the area of the opening into the well is less than the area of the apertures in the arms, and the valve promptly closes.

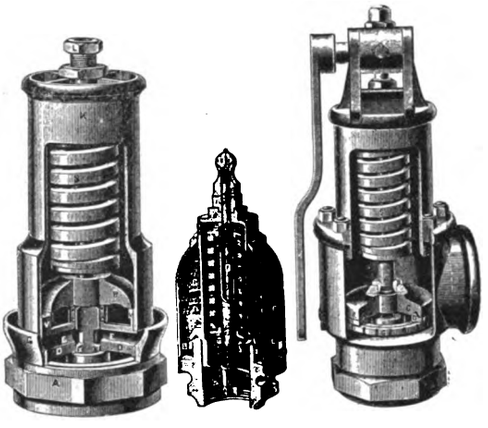

FIG. 3.—CROSBY POP VALVES.

In the Moody muffled form of pop valve the valve proper projects upward through the casing of the valve, as shown by the middle cut in Fig. 3. The upward or outer side of the valve is open to the air at all times, so that the valve is free at all times from any pressure of the out-going steam which escapes through the perforated casing into the open air without a disturbing noise. There is no back pressure in this valve, which opens to greater height than is usual in valves of this kind.

While the "straight Crosby" valve, as shown in Fig. 3, is designed for locomotive use, it will work equally well anywhere, but a less expensive form of valve particularly designed for stationary and marine boilers is also shown in Fig. 3. This valve is known as the Crosby-Meady valve and the interior mechanism consists

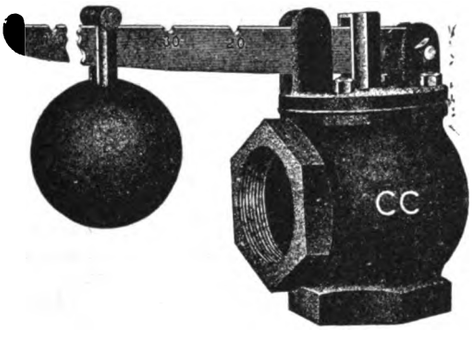

FIG. 1.—LEVER SAFETY VALVE.

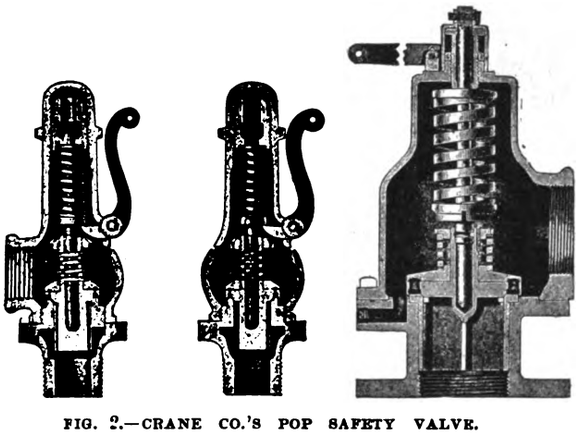

FIG. 2.—CRANE CO.'S POP SAFETY VALVE.

Digitized by Google

of a central spindle, A, which has a slight annular enlargement of its lower end, and rests in a central cavity in the top of the valve, C, being held in place and centrally guided by a flanged nut, B, which is screwed down into the cavity until the flange of the nut rests on the top of the valve. By means of this device any outward movement of the lever lifts the valve, C, from its seat.

The valve, C, is provided with wing guides which fit smoothly into the cylindrical seating, D, upon the top of which the valve rests. The seats of this valve have an angle of forty-five degrees to the vertical axis.

On the outside of the valve seating (forming a part of it) is provided an annular flange, F, the top of which is on a plane with the bottom of the valve seat.

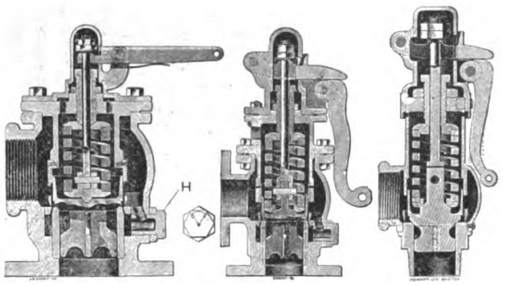

FIG. 4.—ASHTON POP SAFETY VALVES.

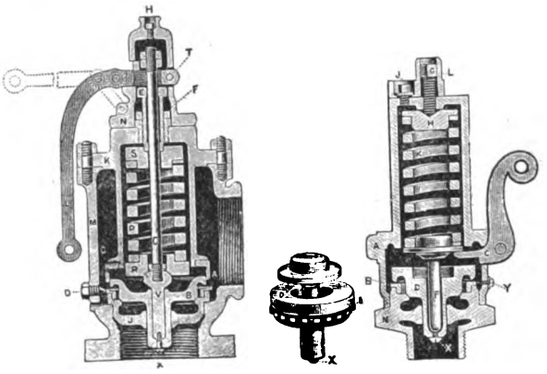

FIG. 6.—LUNKENHEIMER POP VALVE.

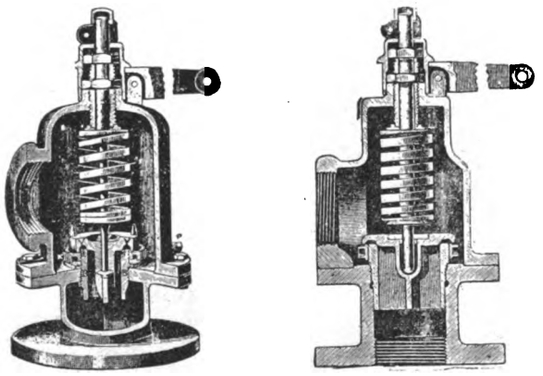

FIG. 5.—HAYDENSVILLE POP VALVE.

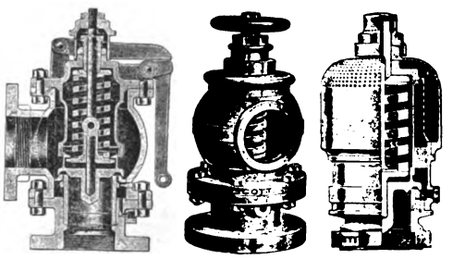

FIG. 7.—SCOTT SAFETY VALVE

Above the flange, F, the metal of the seating is cut away to form a right angle with the valve seat. The valve, C, is also provided with an annular lip, E, the external diameter of which corresponds with that of flange F of the seating. The under face of this lip, E, is also at right angle with the valve seat, and in combination with the seating forms a small chamber through which all the steam must pass to reach the open air—the greater part between the narrow edge of the lip, E, and the flange, F, of the casing, and the remainder through a number of small holes drilled vertically through the flange, F, to connect with this chamber.

Twin valves are made by this concern, the Crosby Steam Gage & Valve Company, Boston, Mass., and they also make special steam heating safety valves, which limit the pressure carried to 15 pounds per square inch. They also make high pressure valves for use when the pressure to be carried is between 500 and 5000 pounds per square inch.

Three types of valves, as made by the Ashton Valve Company, Boston, Mass., are shown by Fig. 4. The first represents the "Lock-Up" form, the second shows a cam lever marine valve, also with lock-up attachment. The third shows the yacht valve made by that company. In all these valves there is a chamber surrounded by a knife-edge lip and enclosed within the walls of this lip and the top of the bushing and valve seat. The knife edge wears down in proportion to the wear of the seat of the valve, thus keeping the outlet of the pop-chamber of the same relative proportion to the inlet, giving an unvarying pop and insuring long service without readjustment.

The supplementary pop chamber is introduced in all Ashton valves over two inches in diameter, and this chamber is connected with the primary pop chamber by a series of holes through the bushing. This arrangement serves the purpose of making a close regulation of the pop by the adjustment of its outlet passage into the discharge chamber by means of the screw plug regulator, H, on the outside of each valve. By adjusting this screw, which is so constructed as to be free from corrosion or any possible chance of sticking, any desired pop can be obtained, that is, the range of pressure between opening and closing can be adjusted as fine as possible.

All these valves above two inches in diameter are fitted with a blow-back head, which forms a chamber enclosing the spring and protecting it from the great volume of steam. Both the inlet and outlet are on the base casting, making it possible to take the valve apart and regrind or otherwise repair it without breaking the connection with boiler or outlet pipe. Testing clamps are furnished wherewith a valve can be locked during a pressure test of the boilers, thereby avoiding the otherwise necessary changing of the blow-off point, and preventing an undue strain on the spring during such test.

From an inspection of the engravings above and hereafter shown, it will be seen that the principle upon which the quick action of the pop safety valve depends is that of reaction. The issuing steam strikes against a lip of the main valve, or against a supplementary ring attached thereto and effects much the same action that is brought to pass when a stream of water strikes the current surface of a turbine bucket. The reactive effect serves to open the valve further, and as the pressure diminishes, to close it quicker when action takes place either way.

Fig. 5 represents two forms of pop valve made by the Haydensville Manufacturing Company, New York City.

In both these valves the form of disc given to produce the reaction effect can be plainly seen, although the form of construction differs some in the two valves, that at the left hand showing a solid nickel seated form, while the other represents the ordinary brass-seated valve. The latter has only a limited adjustment of the screw ring under the reaction lips or knife edge, whereby wear may be compensated for and the degree of pop, or "pounds of waste," kept within bounds, say, within two or three pounds.

The forms of pop valves illustrated by Fig. 6 are made by the Lunkenheimer Company, Cincinnati, Ohio, and present some interesting features in modern

Digitized by Google

safety valve engineering. Two forms of valve are shown, the iron body and the brass form of construction. The pop, on action of the escaping steam, is controlled by the externally threaded ring, B, in the base of the valve, which is easily accessible without taking valve apart, and is held securely in place when set by means of set-screw, Y, on the side of the valve body. If the valve pops suddenly and does not reduce the pressure enough, turn ring B down (further away from the valve disc), and if it pops too much, opening and closing only gradually, turn ring B up (nearer to the valve disc). When the desired adjustment is obtained, secure the ring by means of the set-screw.

In the iron body valve it will be noticed that it is not necessary to change the pressure adjustment when testing the boiler, as the lock screw, H, can be removed and a long set screw of the same size inserted and screwed down upon the valve stem holding disc to its seat while pressure is being applied to boiler. As soon as test is over the set screw can be removed and valve will again be as efficient as ever. The spring and disc are encased and action of valve cannot be effected by back pressure, in case discharge pipe is cramped or muffled.

The three forms of safety valves illustrated by Fig. 7 are known as "Scott" valves, and are made by the Roe Stephens Manufacturing Company, Detroit, Mich. The first cut in the engraving shows their form of marine lock-up pop valve as accepted by the U. S. Government on a basis of one square inch of valve area for two square feet of grate surface. This valve has the reaction form of disc with adjustable ring for changing the pop. The spring is isolated from the steam, and access can be had to the valve without interfering with the outlet pipe.

The second cut in the engraving shows an adjustment apparatus, where by the turning of a hand wheel, two adjustments of pressure may be had at will. Thus, the valve may be set at 90 and 200 pounds and by a turn of the hand wheel, shown at the top of the cut, may be made to work at either pressure at will. Thus, in boiler houses which require a lower pressure of steam in the day time than at night, these valves particularly apply as a simple turn of the hand wheel changes from one pressure to the other.

The third cut in Fig. 7 shows the Scott muffler valve, Richardson style. These valves are so constructed that it is impossible for them to cock or tilt, being guided by the wings at the bottom and a head at top, and nothing more than atmospheric pressure is retained on top valve, and when in operation it cannot be loaded. They are also provided with an adjustable screw threaded ring, by the use of which the point of closing can be easily regulated. The muffler valve is of similar construction to the plain valve, but is provided in addition with a perforated dome-shaped exterior casing with a new design of inside muffler, by which the noise of the escaping steam is lessened to a marked degree, and does not impair the efficiency of the valve, which will give perfect relief to the boiler.

Two types of pop valves as put upon the market by the Consolidated Safety Valve Company of New York are illustrated by Fig 8. The first is a thin nickel-plated valve, made with the Rich-

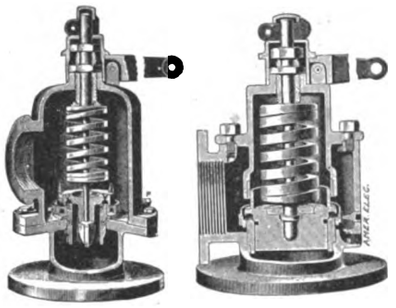

FIG. 8.—POPS OF THE CONSOLIDATED SAFETY VALVE CO.

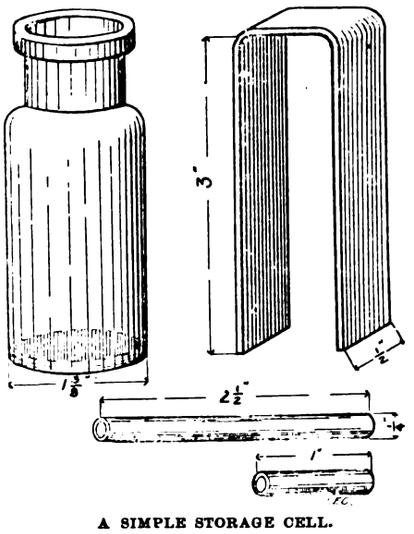
ardson adjustable screw ring, as in fact are all the pop valves manufactured by this company. This style is supplied by that company at all times, unless some special form of valve is specified. The adjusting ring for regulating the pop, also the set screw for holding same in place, is plainly shown. In this valve the spring is placed directly in the blow-off chamber, consequently it is exposed at all times to action of the escaping steam. But in the second cut of Fig. 8, which shows the base-outlet pop valve made by this company, there is a separate compartment for the spring, which protects it from heat and moisture of the escaping steam. This valve is intended for large boilers in electric light plants, while the "Standard" is also adapted to the same service, but is not quite as high in grade as the second cut in Fig. 8. The latter, having a base outlet, i. e., an opening in the lower casting for its discharge, can be taken to pieces without breaking any pipe joints.

## A STORAGE TESTING BATTERY.

BY BENJ. H. GLOVER.



In making electrical measurements it is usually necessary to use some form of battery as a source of e. m. f. For ordinary bridge work a few cells of dry or sal-ammoniac batteries are sufficient and are usually on hand. There is, however, a large class of testing work where a considerable electromotive force is needed. A silver chloride battery of one hundred cells or more is an expensive piece of apparatus and is also a frail affair. It must be used with caution and is liable to be rendered almost worthless by an accidental short circuit or the making of wrong connections.

Having considerable use for a high e. m. f. in various testing work, the writer devised and constructed a storage battery which was not only compact and convenient, but thoroughly reliable and practically indestructible if given ordinary care and attention. The results being so satisfactory, several batteries have since been built along the same lines by those who have examined it, and no doubt the following description will be of value to any who have occasion to use such apparatus or wish to construct a similar battery.

The containing jar consists of a one-ounce wide bottle. This bottle is three inches high and one and one-quarter inches outside diameter, with an opening of three-quarters of an inch clear. The elements are made of sheet lead strips one-half inch wide, seven inches long and one-sixteenth inch thick. Such a strip is bent as indicated in the sketch and forms two elements: the positive of one cell and the negative of the adjoining cell. The two elements in one cell are separated and insulated by two pieces of glass tubing. This tubing has an outside diameter of one-quarter inch. One of the pieces is two and the other one inch in length. The longer tube is used as a filling funnel for the electrolyte and as a separator for the strips. The short piece of tubing serves as a vent for air when filling the bottles and for gases when charging.

In constructing a cell two strips properly bent in shape are separated by the glass strips and a rubber elastic band is snapped over the whole. This keeps the parts together while the cell is being sealed. Some of the regular wax used by storage battery companies should be used for this purpose, as it is not affected by the acid. Considerable difficulty was experienced with the first cells made, due to the fact that common wax was used, which was attacked by the acid, and held a quantity of moisture, which caused the cells to leak and run down rapidly when left on open circuit.

If the bottles are filled up to the neck with some heavy liquid the wax may be

A SIMPLE STORAGE CELL.

flowed about the strips, making an effective seal. Another method, though more laborious, is to place small lumps of the wax around the strips and then seal with a blowpipe.

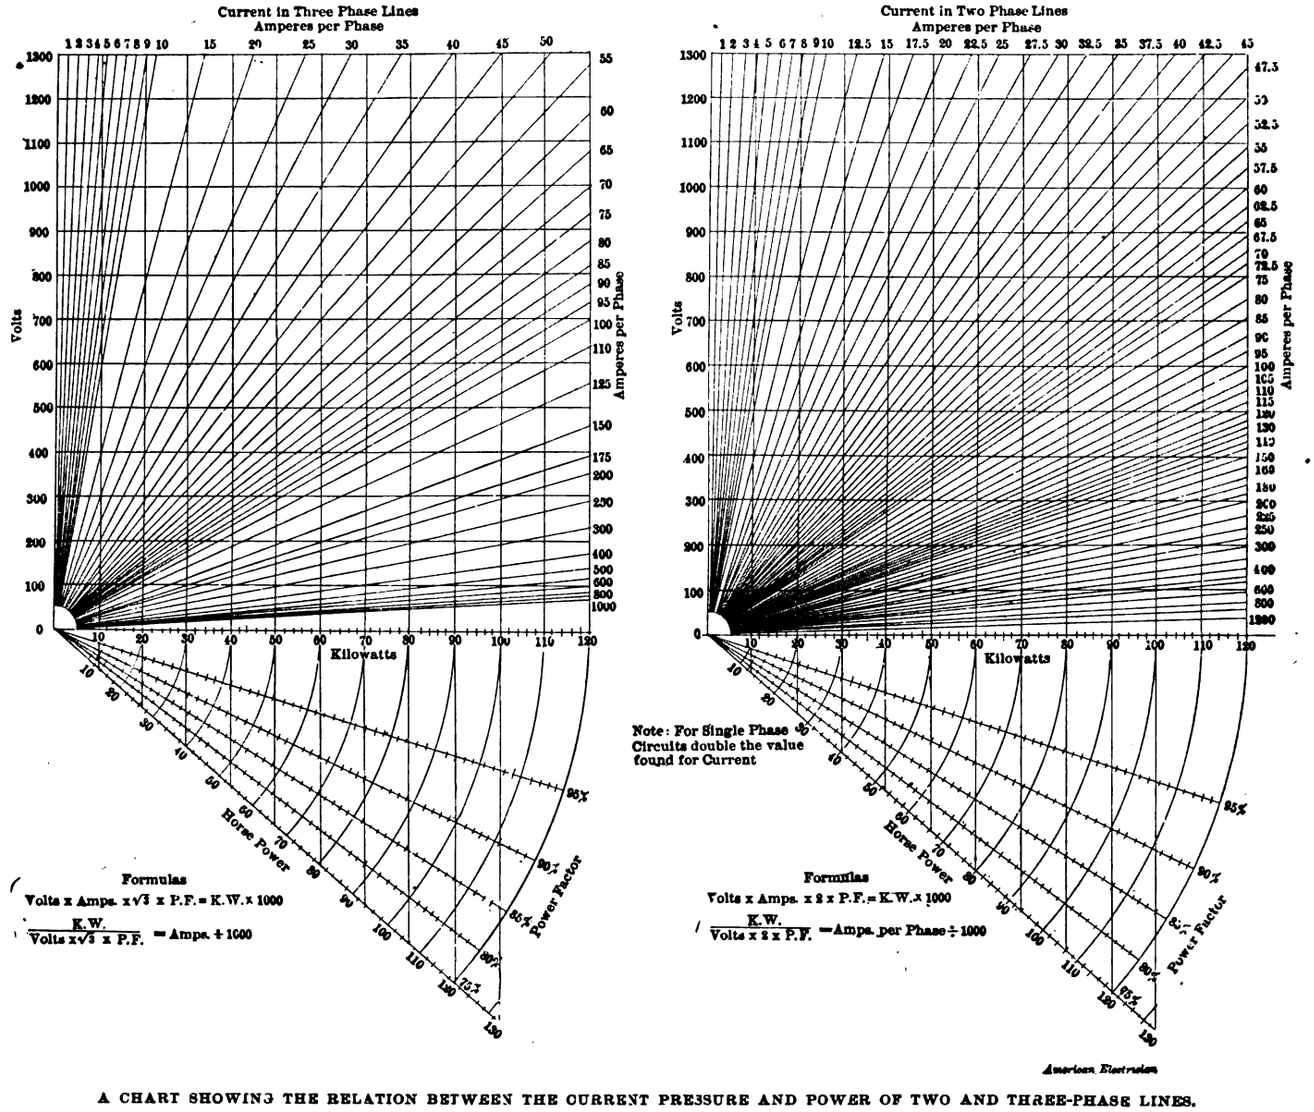
After sealing the cells into groups of any desired number and arrangement they should be filled with an electrolyte com-

Digitized by Google

posed of sulphuric acid and water with a gravity of about 22 degrees Beaume.

The forming of the active material on the plates takes some time, but should be carefully performed, as the more satisfactory results obtained fully compensate for the care and patience exercised. The area of the active surface exposed to the electrolyte is about one square inch. When forming the plates at least two 110-volt lamps should be placed in series when charging from 100-volt mains. Every hour or two the battery should be discharged through the same resistance until nearly exhausted and then recharged as before. This operation must be repeated and continued until the plates are well formed, cutting down the charging current to one twentieth of an ampere as the process advances.

As to the cost, a 50-cell battery was built from the following inexpensive materials:



| | |
|---|---|
| 50 one ounce wide mouth bottles | $ .50 |
| 8 pounds lead (7 in. x 36 in. x 1/16 in.) | .48 |
| 1 pound glass tubing (¼ in.) | .30 |
| ½ pound wax | .10 |
| 1 pint acid (concentrated) | .25 |
| | $1.63 |

## A CHART FOR DETERMINING THE CURRENT IN TWO AND THREE-PHASE LINES.

The determination of the current in the wires of two or three-phase lines for a given number of kilowatts or horse power with a given voltage and power factor requires considerable calculation from the proper formulae, all of which can be readily replaced by the scales printed below. Of these the right hand drawing gives the values for two-phase lines, and by multiplying by two gives the current strength for the same conditions on single-phase lines, while the left hand scale gives the current for three-phase lines. The formulae from which they were drawn are given with them. The directions for their use are as follows:

To find the current per phase for any output at any voltage, look up the vertical line corresponding to that output in kilowatts as determined by the horizontal scale running along the base of the intersecting squares. Follow this vertical line up to its intersection with the horizontal line corresponding to the voltage of the circuit and the current strength in amperes will be found at the end of the diagonal current line intersecting that point. For example, upon the two-phase chart 50 kilowatts at 1100 volts shows approximately 22½ amperes per phase. In case the circuit is single-phase the number of amperes for this load at this voltage would be 45. If no diagonal line passes through the point of intersection the value of the current may be found by interpolation between the diagonal lines next above and below. For example, 70 kilowatts at 900 volts shows a current strength midway between 37½ and 40 amperes, or about 38¾ amperes. By noting the position of the decimal point any current at any voltage may be determined. For example, to determine the current at 2200 volts for a given load the current at 220 volts may be read off from the chart and divided by 10; similarly, to determine the current for 500 kilowatts. 50 kilowatts may be applied to the chart and the result multiplied by 10.

If the load is given in horse power instead of kilowatts, it may be followed up

A CHART SHOWING THE RELATION BETWEEN THE CURRENT PRESSURE AND POWER OF TWO AND THREE-PHASE LINES.

Digitized by Google

vertically from the scale on the lowest radial line. For eexample, 80 horse power at 600 volts gives 50 amperes. The other radii are for use in case the power factor is less than unity. In this case the kilowatt line should be followed down vertically to its intersection with the radius representing the power factor of the circuit, and the circle intersecting this point should be traced around to the vertical and carried up into the scale of volts and kilowatts. For example, 70 kilowatts with a power factor of 80 per cent. shows an apparent load of 88 kilowatts, which may be followed up to—let us say—1100 volts, giving 40 amperes.

By combining these various methods a given number of horse power with a given power factor may be reduced to current. For example, 106 horse power followed up vertically shows 80 kilowatts, which, with an 80 per cent. power factor, shows 100 apparent kilowatts and a current dependent upon the voltage as above pointed out. The chart is also reversible, a given number of amperes at a given voltage being readily reducible to kilowatts and horse power if the power factor is known. For example, 70 amperes at 300 volts is evidently 43 kilowatts, or 56 horse power, if it is non-inductive. If it has a power factor of 90 per cent., the same number of amperes at the same voltage becomes 39 kilowatts or 52 horse power. The same methods are exactly applicable to the right hand scale of three-phase systems.

The lower diagonal or radial lines may be used to represent the efficiency of a motor in place of the power factor; e. g., a 90 kw. motor having an efficiency of 90% would require 100 kw. to drive it and the current required can be found as above.

These charts were drawn up by Mr. Stephen Q Hayes, to whom the readers of the American Electrician are indebted for their publication.

## Letters on Practical Subjects

### An Improvement in Coherer Construction.

*To the Editor of American Electrician:*

Sir—I have read with considerable interest the article by Prof. Jerome J. Green on wireless telegraphy in the July issue of the American Electrician. The form of coherer and tapper shown in Fig. 4 is an exceedingly desirable and compact arrangement and simply constructed from existing materials. There is, however, more in the device than seems to have been mentioned in the article, and I venture to make the suggestion that if the shell or dome of the buzzer were made of a steel or iron casting, a great deal of trouble due to waves emanating from the vibrating contact of the tapper would be eliminated. In such a form the device would be an attractive and useful piece of physical apparatus and in due time of commercial value; in short, it seems to me that Prof. Green's coherer and tapper suggest a very desirable standard form for the apparatus.

GEORGE T. HANCHETT.

New York, July 17, 1899.

### A Name for the Self-Propelled Vehicle.

*To the Editor of American Electrician.*

Sir—The mechanical or self-propelled vehicle for use on streets is drawing so much public attention and meeting with approval and demand so rapidly that it seems strange that no satisfactory name has as yet been given these vehicles, and as this question is one that has come up recently in some of the papers, I have taken the idea under consideration, and I believe, finally solved the problem.

To such vehicles the name horseless carriage, automobile, motor vehicle, electric carriage, auto-car, electro-mobile, gasolene wagon, etc., cannot be used when speaking of the operator and retain the name of the vehicle, or distinguish the sex of the operator, or in fact, distinguish the operator at all, let alone any distinction of the act of running such a vehicle. What is required is a name that in speaking of an operator of either sex or the act of driving, will carry with it the name of the vehicle itself, and also a name broad enough in its application to apply to any form of self-propelled vehicle, whether electric, gasolene, steam or any other form of motive power.

The name I wish to suggest to the public is a name which fulfills all of these requirements, and that is the name AUTOBAINE, which, translated, means automatic wagon, BAINE, being derived from an old Greek word, meaning wagon; so we have for the name of the vehicle, AUTOBAINE. AUTOBAINEER, as applied to a man operator, AUTOBAINEESS, as applied to a woman operator, and AUTOBAINING or AUTOBAINEERING for the act of using the vehicle, in addition to which this name is applicable to any kind or form of self-propelled vehicle.

C. E. WOODS.

Chicago, Ill.

### Polyphase Generators, Transformers and Motors.

*To the Editor of American Electrician:*

Sir—I notice in a recent issue of one of your contemporaries an article on the above topics, in which considerable space is devoted to a description of polyphase transformers. Four types are mentioned, as follows: "Two-phased transformers, which simply raise or lower the potential; three-phased transformers, which act similarly; two-phased-three-phased transformers, which receive two-phased currents and deliver three-phased currents, at the same potential, or higher or lower, as the case may require; and three-phased-two-phased transformers which receive three phases and deliver two, at even potential, or higher or lower potential."

In the plant with which I am connected polyphase apparatus is used, but entirely with single-phase transformers; the latter are also used to transform from two phases to three phases and vice versa. I have always understood that this was universal practice in this country and have never heard of any plant in which polyphase transformers were used. If such instruments are in use I should like to see descriptions of them in your columns.

The same article advises engineers that "good practice as applied to revolving armature machines of either two or three phases is to use 1000 volts or less at the machine, step-up transformers at the switchboard to raise the pressure to 2000, 3000, 5000 or 10,000 volts, according to outside conditions." If this is the case universal practice in this country on 2000-volt systems, which are now standard for alternating central stations, must be bad, since the 2000 volts are universally, one may say, generated directly in the machines, whether they have revolving armatures or revolving fields.

I noticed also another slight departure from actual facts, to which I call attention only to emphasize the arraignment made below, and that is the statement in the same article that synchronous motors must have brushes and collector rings. In my own plant we use an inductor machine as a synchronous motor and it has, of course, neither brushes nor collector rings.

It would seen to me that publications such as the one referred to, which has recently commenced dabbling in electrical affairs and which aims to give elementary instruction to practical men, should be careful that these instructions conform with the conditions of practical work.

A. R. B.

Niagara Falls, New York.

[The statements of the writer given above are correct. No polyphase transformers are commercially used in any instance in this country, although they are to a limited extent on three-phase plants in Europe. The generation of 2000 volts in revolving armature machines is common and good practice, and synchronous motors—if of the inductor type—require no brushes or collector rings.—Editor.]

### The Value of Feed-Water Heaters.

*To the Editor of American Electrician:*

Sir—In a paper which is abstracted in your issue of July, 1899, entitled "A Local Transmission System," certain reasons have been set forth as to why "the Union Station was designed and equipped with all auxiliaries electrically operated, the steam from the boilers being used only in the main engine."

The deductions will not hold, either in theory or in practice, if feed-water heaters are considered for the service. A conservative and perfectly safe estimate of the difference between running everything condensing and running a sufficient

Digitized by Google

part of the plant non-condensing to supply the exhaust steam necessary to heat the feed-water up to say 210°, can be readily made.

Let us assume the case of a plant developing with one or several large units 5000 i.h.p., with auxiliaries belt-driven, or electrically operated (though the belt-driven is the more economical) doing this work on a consumption of 15 lbs. of steam per h. p. per hour. Then 75,000 lbs. of water will have to be made into steam per hour, from water from a hot well, at say 100° F.

Against this let us compare another plant, doing the same amount of work with one engine of say 500 h. p., run non-condensing, and the rest of the engines (4500 h. p.) operating condensing. With the same steam consumption the condensing engines will require 67,500 lbs. of steam per hour; if the non-condensing engine will require one-third more steam per h. p. than the condensing engine, it would be a very liberal estimate. On this basis the 500 h. p. non-condensing engine will require 10,000 lbs. of steam per hour. Total amount of heat required per hour for this plant would then be that for 77,500 lbs. of steam, less the heat conserved from the exhaust from that non-condensing engine. If we take the most extravagant estimate of the losses from work done, radiation, etc., at 25% of the total amount of the heat in the steam used by this non-condensing engine, we could still save 75% of the heat in the steam, or the equivalent of 7500 lbs. of steam, for about this quantity would be needed to raise the temperature of the hot well water from 100° (the same temperature as in the other case) up to the boiling point.

Deducting this from the gross total of 77,500 lbs. gives the net total of heat required for generating steam as the equivalent of 70,000 lbs. per hour. That is, instead of having to burn coal for evaporating 75,000 lbs. of water per hour, it will only be necessary to burn the coal required to evaporate 70,000 lbs. of water per hour; the difference is 5,000 lbs. in favor of running the auxiliaries with steam.

The equipment required for running the auxiliaries by steam costs considerably less than the other, and the saving will be in the neighborhood (under the actual conditions) of 8% of the total fuel bill.

The plain truth of the matter is that unless the temperature of the feed-water entering the boilers is 200° or over, no one can afford to run any auxiliary condensing, direct-driven, or with a motor. The exceptions to this general statement only prove the rule.

The 5000-h. p. plant which we suggested will stand the most careful investigation, and the only point that can be made against it—granting that good practice requires boilers to be fed with hot water—is whether it is better to use economizers or feed-water heaters, as suggested. Both heaters and economizers utilize waste products; if either one will supply all the heat that can be conserved there is no need of utilizing the other.

In favor of the above plan, if with it the open heater is used, there is a less first cost of installation, a less cost for upkeep, no deterioration of the heating qualities, and a certain amount of purification for the feed supply. The heating results given are practically the same, so that when you come down to it one can better get along without an economizer than he can without a properly designed open feed-water heater.

Many engineers are of the opinion that because steam auxiliaries require a great many more pounds of steam per horse power per hour for their operation than the same power can be developed in a condensing engine, that they are wasteful and should not be used. These people are the ones we wish to enlighten.

The actual heat taken from steam for work done is, of course, exactly the same in all engines, roughly, 43 heat units per minute per horse power. Even supposing that steam auxiliaries require 150 lbs. of steam per horse power per hour, 95% of the heat in this steam can, we believe, be used in a heater for heating the feed-water, since 5% will more than account for the work done and for radiation. It must not be overlooked that even with engines taking steam practically the full length of the stroke all of the initial condensation will be re-evaporated, because the sudden fall in pressure, when the exhaust valve is opened to atmospheric pressure, will liberate enough heat for this re-evaporation.

J. C. JONES.

## Electrical Catechism

*322. What are the fundamental principles upon which the electric motor operates?*

Every current is surrounded by a magnetic field of force which distorts any other magnetic field in the vicinity; the two combine into a resultant field whose lines of force tend to become as short as possible, thereby tending to move both sources to a new arrangement such that the lines may be as short as possible. In accomplishing this result, what is called the "field" is usually the space between the poles of an electromagnet; the current is in wires carried on or near the surface of a cylinder of laminated iron, the combination of iron and wire being called the "armature."

*323. Are alternating current motors based upon the same principles as those for direct currents?*

The fundamental principles are the same, although in the application there are many differences. With direct current motors the currents for both the field and the armature are taken from the external circuit; with most of the motors for alternating currents the field is magnetized by current taken from the external circuit, while the current in what corresponds to the armature is usually obtained by induction.

*324. Will an alternating current motor work upon a direct current circuit?*

A few small a. c. motors will work on a direct current, but most of the larger ones will not.

*325. Will a direct current motor work upon an alternating current?*

Almost any d. c. motor will run when an alternating current is sent through it; but it will not ordinarily develop any considerable amount of power, unless wound specially for the purpose and unless the field magnets are made of laminated iron and precautions are taken to avoid induced currents in stationary parts of the motor.

*326. What kind of motor is the easiest to understand?*

Perhaps the simplest is the "oblique approach" motors made for toys or small sizes only. These must usually be started by hand. The moving and stationary parts are both magnetized by the same coil, and are so designed that the path of the magnetic lines of force becomes shorter and shorter as the armature revolves until it reaches the shortest path, when the current is cut off for a short time and the attraction ceases until the momentum has carried the armature past. Figs. 1 and 2 illustrate the principle involved. Suppose that the armature is in the position shown in Fig. 1, when current is sent through the coil around the pivoted piece N-S. The current sets up magnetic lines which extend through the iron circuit somewhat in the direction shown by the dotted lines. The tendency of these lines to shorten draws the movable piece around to the position shown in Fig. 2. It would stop here, because in this position the air gap is shorter than in any other position; but a commutator is arranged so that the current is cut off at this point and the moving piece keeps on moving by its own momentum, until it reaches a position one-quarter turn ahead of the position shown in Fig. 1, when

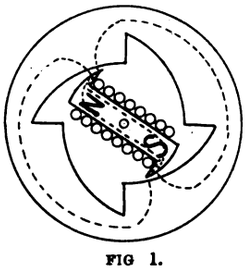


FIG 1.

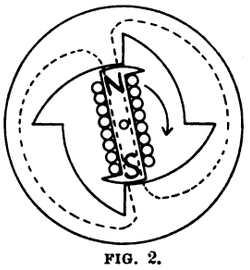

FIG. 2.

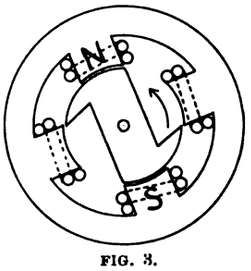

FIG. 3.

Digitized by Google

current is again sent through the coil and the pivoted piece moves on again through a similar set of changes. Some motors of this type have the coils on the stationary part; which has usually more than one pair of coils and poles, the current going first through one pair and then through the other, as suggested in the third figure.

*327. In the "oblique approach" motors, which part is the armature and which the field?*

Ordinarily the moving part would be called the armature, and the stationary part the field. This is easy to see in Fig. 3, but there is room for discussion regarding the motor shown in Figs. 1 and 2.

*328. What class of motors is easiest to understand next?*

Those in which the moving part has two or more projecting ends like those on the armatures of the "oblique approach" motors, but whose field magnet and armature have separate coils. Examples of these are shown in the accompanying figures. The simpler one is the "Edison" toy motor, Fig. 4, whose field is a sort of horseshoe magnet, and whose armature is the shape of the capital letter I or H. The two ends of the coil upon the armature are connected respectively to the halves of a split sleeve, which is carried upon the shaft and upon which two stationary brushes rub; it is evident that if these brushes are set properly, one brush will press against one part of the sleeve for one-half a revolution of the armature, and upon the other part of the sleeve during the remainder of the revolution. If current is sent through the motor when the armature is in the position shown in the figure, the magnetic lines of force will pass through the circuit and in shortening will draw the armature to the horizontal position; now, if the brushes have been arranged properly, the commutator will have turned around far enough so that each brush presses against a different bar and the current, goes through the armature in the opposite direction; the armature and field now repel instead of attract, and when the momentum has carried the armature past the dead center it will be attracted in the other direction, and so the rotation will continue.

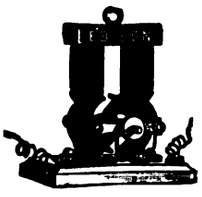

FIG. 4.

*329. How does the "Porter" motor operate?*

This motor, which is shown in Fig. 5, has three poles in its armature. The commutator likewise is in three sections. The brushes are placed diametrically opposite, so that they press against only two of the segments most of the time. Current is sent through the two poles which are in the position to pull the hardest, and when one pole gets to the dead position, where it tends to stay, current is cut off from it and sent into another pole. This motor has no dead center, and will start in any position.

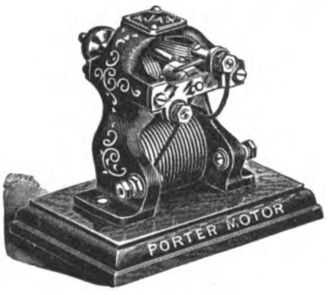

FIG. 5.

*330. How are the armatures of larger motors made?*

The iron core is in the shape of a cylinder having wire wound over its entire surface, or in grooves upon the surface; the wire is wound in sections, which are connected in series with each other, and are connected with the successive bars of a commutator. A "smooth core" armature has the wire upon the surface, while a "toothed," "slotted" or "tunnel wound" armature has the wires in slots or in holes just below the surface. Fig. 6 shows the external appearance of a smooth core armature, while Fig. 7 shows the commutator.

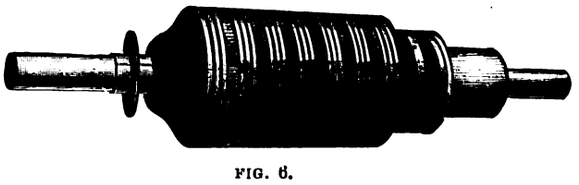

FIG. 6.

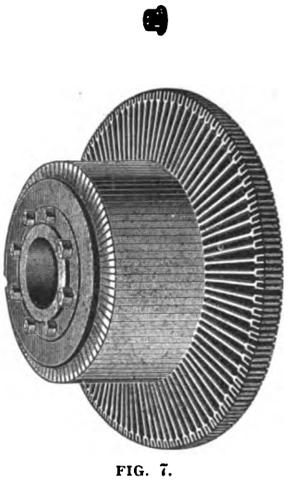

FIG. 7.

*331. What causes a surface wound armature to rotate when current passes?*

The armature is in a strong magnetic field which becomes distorted more or less by the magnetic effect of the current in each of the wires on the surface. The action of each wire may be considered as something like that shown in Fig. 9, where there is a strong pull tending to move the wire in between the poles of the magnet. In the case of the actual armature, the lines of force would naturally go into the armature by the shortest path through the air; that is, would go radially. But the magnetic force about the current deflects the lines and makes them traverse a longer path, somewhat as indicated in Fig. 8, in which circles represent wires, current going toward the paper in those with crosses and toward the observer in those with dots. The effort of the lines to shorten causes the wires to move in the direction indicated by the arrows and thus rotate the iron armature core to which they are fastened. As the wires move to such position that they would pull in the opposite direction, the commutator sections to which they are connected pass under the brushes, and the current is reversed and they still pull in the same general direction.

# Queries and Answers

What voltage is there between the points of the two carbons in the leading types of enclosed arc lamps for use on 110 volt direct current circuits? H. A. M.

80 to 85 volts.

I have a standard Western Union 150-ohm relay which I wish to rewind to 20 ohms. Please let me know what size wire would be needed to wind the coils to that resistance. H. S. K.

About No. 25 wire would be best for that purpose.

Please be kind enough to tell me the ratio of difference between copper and platinum wires of the same diameters. C. S. W.

Platinum wire has about 5 2/3 times the resistance of copper wire.

The main Western Union lead is built north and south on east side of a street. A home telephone company with a heavy lead (8 ten-pin arms) is built directly over on same line with some copper metallic, but generally common return, on which they have endeavored to prevent grounds. Primary wire from 2000 volt alternator passes between the two leads, cutting their line at right angles and extending east 10 ft., where a transformer is located on pole. There is four feet of clearance on both leads. Would that increase lightning hazard and why? We have lost two transformers, while no trouble has been experienced on southwest corner under Postal main lines. E. R.

With the clearance mentioned it is difficult to see how the existence of telephone and telegraph leads can possibly increase the lightning risk on the lighting wires.

What is the proper length of air gap for a swinging ball lightning arrester on a 110 volt circuit? J. H. D.

The air gap should be made very short with this low voltage, as there is no danger of the current jumping. About 1/32 of an inch is suitable. The length of the gap must be increased for high pressures, especially those of many thousand volts.

What temperature centigrade is given in an electric furnace such as is used in the manufacture of calcium carbide, and what is the temperature at the electrodes of a 2000 c. p. arc lamp, consuming practically 10 amperes of current? C. H. M.

The temperature of either 7 or 10 ampere arc lamps is practically that of the melting point of carbon, which has been estimated at 3500° C. That of the calcium carbide furnace is probably somewhat less as the carbons are not melted.

(1) What would be the proper dimensions of a good common medical coil and what amount and size of wire for primary and secondary?

(2) What size or strength of motor will it take to run a common sewing machine?

(3) I have a 16 light 110 volt dynamo, shunt armature, wound with No. 17 wire, 4 lbs. What amperage will it give at full speed?

(4) Can you give me the address of any one charging storage batteries by wind power in a small way, say about 2 h. p., and are they a success in every way? D. W. M.

(1) 2 ins. in diameter by 4 ins. in length. Primary ½ lb. of No. 12 wire. Secondary 1 lb. of No. 24 wire. (2) A 1/12th h. p. or a 12-in. fan motor will do the work. (3) 10 amperes. (4) This is not being done commercially and is a very difficult thing to do successfully.

I have a telephone line from station to office, length about two miles. It is strung on the poles of our 2200 volt a. c. circuit with frequent transpositions, but the line is very noisy. Would it reduce the noise to join the two wires of the circuit together at each end, thus placing the two wires in parallel, and connect the instruments between the ground and the overhead line? My theory is that the induced currents will simply flow backward and forward around the line and not affect the instruments much. F. C.

The trouble would probably be increased as the inductive effect of the circuit consisting of the overhead wires and the ground would be greater than that of a circuit between the two wires. The trouble could be largely reduced by putting in a repeating coil at each end of the line.

How can I find the proper size of wire for the three-wire system? C. S. R.

The positive and negative conductors should be ¼ of the size for the same percentage drop with the same load on the two-wire systems, i. e. calculate your wire by ordinary wiring tables for 110 volts for the total number of lamps and then choose a size with ¼ the circular mils found. The neutral should be the same size as the other conductors.

(1) Is there a device on the market for transforming the current from a 110 volt direct current circuit so that it can be used instead of batteries on telephone systems?

(2) On Edison three-wire systems will an ammeter indicate correctly if placed on lead from dynamo which connects to neutral bus? J. L.

(1) Yes, small motor dynamos with single armatures and two commutators are made for this purpose by several makers, notably the Crocker-Wheeler Electric Company, New York City, and the Holtzer-Cabot Electric Company, Boston, Mass. (2) Yes, the ammeter will indicate the load of the dynamo to which it is connected.

(1) If a high tension arc circuit were to be opened at any point, how would the E, R and C be affected?

(2) If a generator for such service were to be instantly short-circuited, what would be the action of E, R, C?

(3) If any electrical conductor could be extended to both sides of an arc circuit, thus cutting out a given number of lamps, how would E, R and C be affected?

(4) In operating an alternating arc lamp is resistance on one side of the circuit sufficient?

(5) If one ampere is to be received at a pressure of 100 volts, the distance being one thousand feet from the power generator and two volts are to be lost in transmission, what must be the total resistance of the positive and negative wires minus the resistance of the lamp? L. D.

(1) The resistance would rise to an infinite value and the current would fall to zero. The electromotive force would, for an instant, rise considerably, owing to the effort of the machine to regulate for the increased resistance, combined with the self-inductive kick of the fields. (2) The instant after short-circuiting such a machine the current would rise somewhat, but would be choked back by the armature reaction. As soon as the regulator could shift the brushes or vary the field resistance this rise would be corrected. (3) At the instant of cutting out the lamps there would be the same effect as under (2), but to a smaller extent. (4) Yes. (5) 2 ohms.

Can the rectifier described in the June issue of the American Electrician be changed so as to render it a satisfactory direct current generator or motor for 110 volt circuits, at a speed of 1200 r. p. m.? If so, what changes will be necessary? What is its power when used as an alternating current motor? B. E.

Yes. The machine will make a good 110 volt dynamo or motor if the following changes in the design are made:

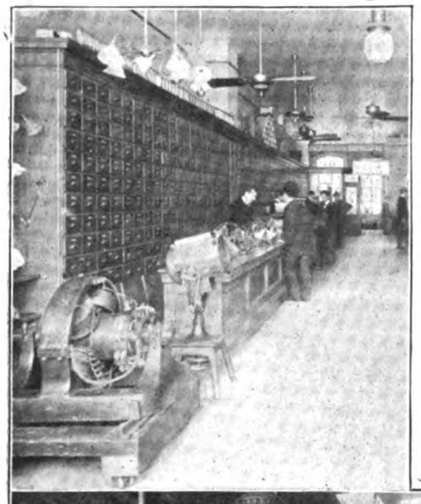
The armature may be of the same general dimensions, but the number of slots should be increased to 16, making them 7/16 in. deep by 7/32 in. wide. The coils should preferably be form wound, of No. 27 double silk-covered wire, 3/16 in. square in section, and to cover 90° of the periphery of the core. Each slot will contain a half of two separate coils, the halves being placed one over the other. Each slot will then contain 200 conductors, each coil 100 turns, and when connected as a series wound armature, it will generate 110 volts at a speed of 1200 r. p. m.

The field may be of the same general form and dimensions as shown, but having its coils wound to size with No. 29 double silk-covered wire, instead of the wire indicated in the article. The coils will then have about 1500 turns each, and the shunt current will be almost exactly ¼ ampere. Allowance has been made for a rheostat in the field, which will increase the field current by 10 per cent. if necessary.

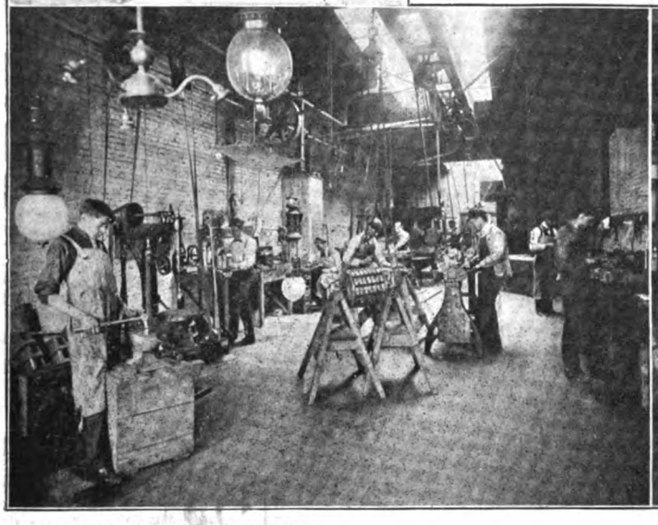
With the above winding the machine when running as a generator should carry two 16 c. p. 110-volt lamps without serious heating. And running as a shunt motor on the 110 volt mains its output would be somewhat more than ⅛ h. p.

The speed suggested of 1200 r. p. m. might be advantageously raised to 2400 r. p. m., a perfectly reasonable speed for so small a machine, unless there is some special reason for adopting a slow speed.

If 2400 r. p. m. be adopted the same armature winding outlined above could be connected as a parallel winding, and the output would now become about 2 amperes at 110 volts, that is, the machine would carry four 16 c. p. lamps, or would give about ¼ h. p. as a motor.



Incidental to changing over the design to that of a direct current generator or motor, the commutator could be reduced considerably in size, and the collector rings omitted, thus permitting the arms on the field casting to be shortened and so adding to the neat and compact appearance of the machine.



Brake tests made on the rectifier when running as a synchronous motor on the ternating current line show that it develops a little under 1/10 h. p.

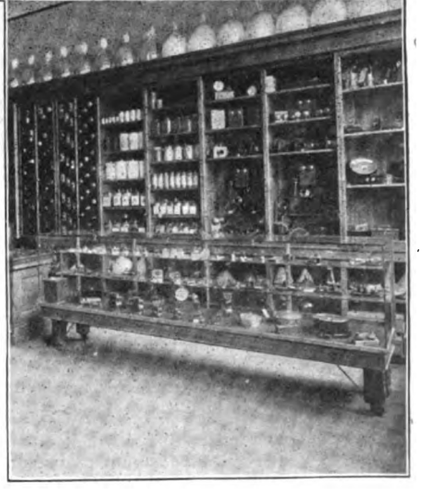
## AN ELECTRICAL SUPPLY HOUSE IN DETROIT, MICH

The Michigan Electric Company, whose new quarters are illustrated in this issue, began business March 1st, 1893, as electrical contractors for wiring and general construction.



ONE SIDE OF THE SALESROOM.
SHOP ON FOURTH FLOOR.

STOCK AND
SHIPPING DEPARTMENT.

FIXTURES IN SALESROOM.

September 24th, 1898, its property was almost completely burned out by a fire of unknown origin, but undaunted, the company rented temporary quarters opposite the old location while the fire was still burning, and before the crowd had dispersed had temporary signs up, telephone in and business resumed. Fortunately the fire did not destroy any valuable records, so such a complete statement of the loss was immediately made out as enabled a settlement to be reached with the fire insurance companies the day that it was presented; this fact alone evidences the company's thorough and able management of business affairs.

The rebuilding of the old quarters having next been arranged for, President Joseph E. Lockwood visited the leading wholesale and retail electrical and hardware houses of the country and studied in detail their arrangements, fixtures and methods, with a view to securing in the new quarters the best possible combination to meet the requirements of the business and utilize to the fullest possibility the space available.

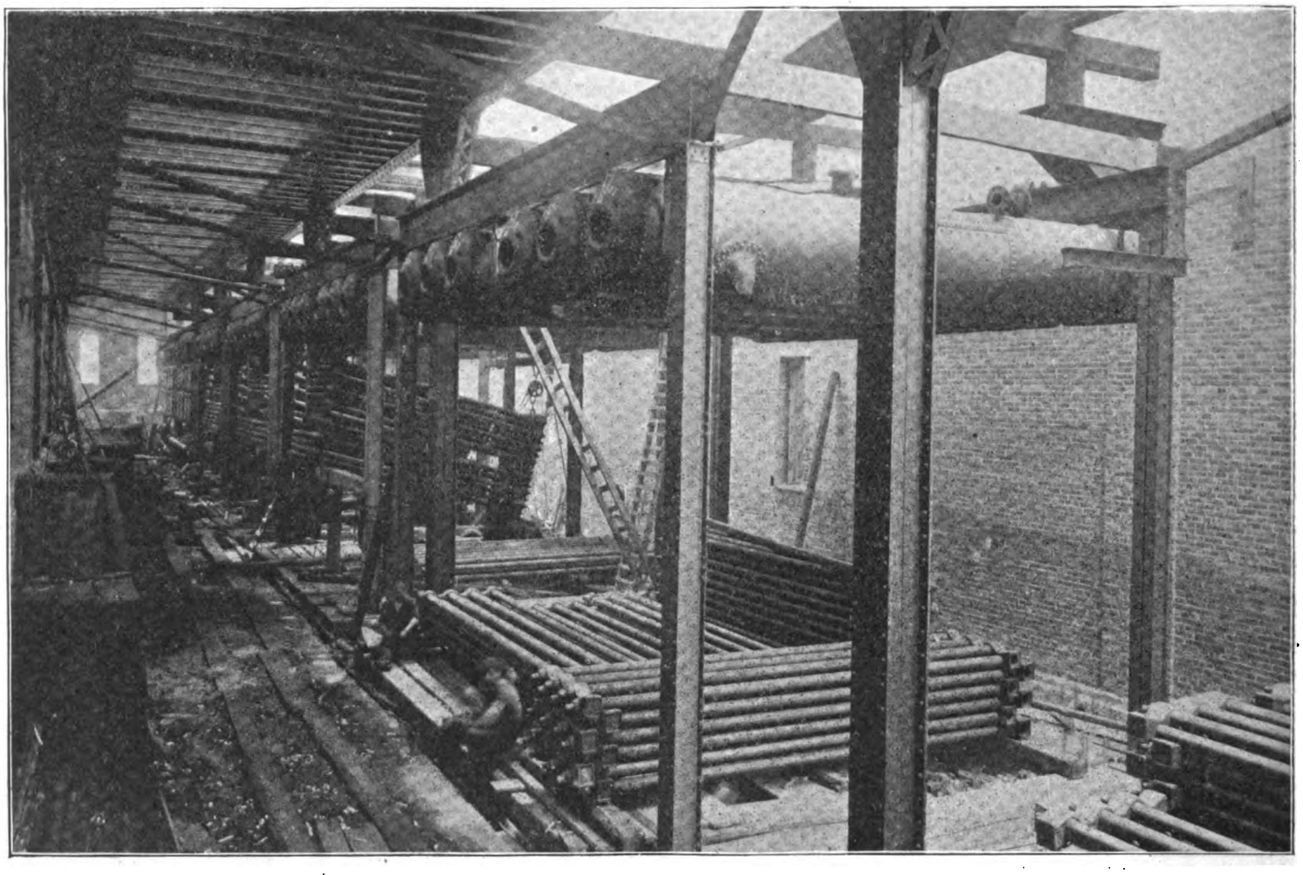
December 10th, 1898 (less than 90 days after the fire) the company moved back to the old location, which meanwhile had been entirely rebuilt from the ground up, excepting only the bare walls, and today it has one of the handsomest and most convenient quarters of all the general electrical houses in the country.

The business now covers everything in the electrical line including supplies and machinery, wholesale and retail, repairing electrical machinery and appliances, contracting for anything from installing a bell job on time and material, to furnishing and installing complete plants for light, power and railways. In addition the house has an experienced engineering force competent to handle every class of electrical work. It is manufacturers' agent for many of the leading electric specialties, such as Cutter switches, Western Electric fan motors, Atkinson's protected rail bonds, Creaghead overhead material and brackets, Chloride accumulators, Bryan Marsh incandescent lamps, etc., and for very large contracts represents the well known firm of J. G. White & Co., of New York. The company is also itself a manufacturer of electric and combination fixtures from both standard and special designs, of electric signs, decorative devices and other specialties.

The supply department occupies the first and third floors and basement. On the first floor is the general salesroom and supply department office.

The third floor is the receiving and shipping room and also provides space for part of the reserve stock. It is connected with all other floors by two power elevators (one passenger and one freight), and by a Sargeant hand-power package elevator, as well as by telephones and speaking tubes. The basement provides space for additional reserve stock and for tools of the construction department.

On the fourth floor is located the machine shop, which, with its plating, polishing, stock and tool rooms, is a complete factory in itself.



The lines along which the electrical business of the country will develop are of course matters of conjecture, some reading aright the signs of the times, to their profit; others the reverse. This firm believes that the bulk of the business of the country will not be secured by any one or two large centers of trade, but that it will be divided into natural sections in each of which the greater part of the business will go to whichever house is best located and adapted to meet its needs promptly and satisfactorily; believing this, the company has confined its efforts to, and has sought to provide for the needs of its section chiefly. The steady and rapid growth of its business during the depressed business period now passed is, it thinks, undisputable evidence of the correctness of its belief.

## THE BOILER EQUIPMENT OF THE NEW POWER STATION OF THE CONSOLIDATED TRACTION COMPANY OF PITTSBURGH.

The new generating station which supplies power for a large part of the street railways in Pittsburgh has some unusual features in its boiler room, a view of which, while under construction, is shown in the accompanying illustration.

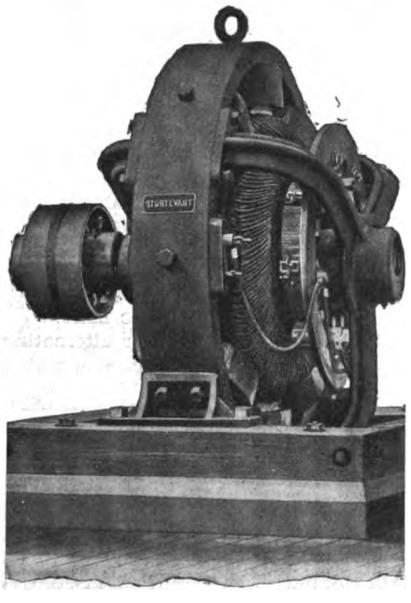
The equipment consists of six batteries of forged steel type sectional water tube boilers of special design made by the Babcock & Wilcox Company. Two boilers constitute a battery, and each battery is rated at 750 h. p. In order to economize floor space, these boilers are shorter and higher than the usual type. Each is made up with three 36-in. drums, 20 ft. long, and 18 sections of tubes, each 15 ft. long, giving about 4000 sq. ft. of heating surface. They are designed for a pressure of 200 lbs., and were tested under hydraulic pressure of 300 lbs. The fire boxes are equipped with the Hawley down draft furnaces, having a grate surface of 66 sq. ft. The furnaces are guaranteed to show 10 per cent. greater efficiency than the ordinary flat grate and to be able to burn 40 lbs. of coal per square foot of grate per hour, and to reduce the smoke by 92 per cent. The boilers with the Hawley furnaces are guaranteed to develop 75 per cent. efficiency with less than 1 per cent. of moisture at full load, or 1½ per cent. at 50 per cent. above rating. In tests which have been made the above guarantees have been attained. There are six unlined iron smoke stacks, one for each battery. Each stack is 66 ins. in diameter, and rises 147 ft. above the grate bars, giving a draft of 1 in. to 1½ ins. of water under ordinary conditions. The breechings and stacks are carried on special supports entirely independent of the brick boiler setting.

THE BOILERS OF THE CONSOLIDATED TRACTION COMPANY'S POWER HOUSE UNDER ERECTION.

## THE FEATURES OF A LINE OF MULTIPOLAR DYNAMOS AND MOTORS.

The field ring which also constitutes the frame of the machines illustrated on page 399, is made of three different materials for the different sizes. The two smaller sizes have field rings of wrought-iron, to which are bolted the eight radial poles. Wrought-iron was adopted for the small sizes, as it was impossible to get steel castings that were satisfactory from a mechanical as well as magnetic point of view. In the next five sizes the field rings are made of steel castings, which, for these sizes, leave little to be desired as regards magnetic qualities. To these rings the radial poles are bolted the same as in the smaller sizes.

For the three larger sizes of machines cast iron has been adopted for the field ring, as with steel or wrought iron the cross section necessary for magnetic purposes is so small compared with the linear dimensions that even if the frame had the necessary mechanical strength, it would present a very weak appearance, and besides be very unstable, on account of its great height and light weight. By the use of cast iron, stability is given to the machine, and at the same time the appearance for strength is greatly improved. Instead of bolting the poles to the ring, as in the case of wrought-iron or steel fields, the poles are cast-welded into the ring and are not removable.



In all cases wrought-iron field cores are used, as this gives the highest efficiency in the field, giving a maximum magnetic field with a minimum weight of iron and copper.

One of the distinctive features of these eight-pole machines is the cast-iron pole shoe, which by its peculiar shape and size is one of the main elements which render these machines capable of extreme variation of load without sparking at brushes and without any shifting or adjustment whatever. On all sizes of machines which have the field cores bolted to the ring, these pole shoes are stud-riveted to the wrought-iron cores and constitute practically one piece. On those sizes in which the wrought-iron cores are cast-welded into a cast-iron field ring, the pole shoes are secured to the cores by means of set screws.

As these motors are designed with special reference to low speed and high efficiency, great difficulty has been experienced in arriving at a size of armature that would be favorable to high efficiency at partial loads, and at the same time

Digitized by Google

allow room for the necessary amount of copper. The proportion of copper to iron must necessarily be great in order to keep the armature resistance at a reasonably

THE STURTEVANT M. P. 8 MOTOR.

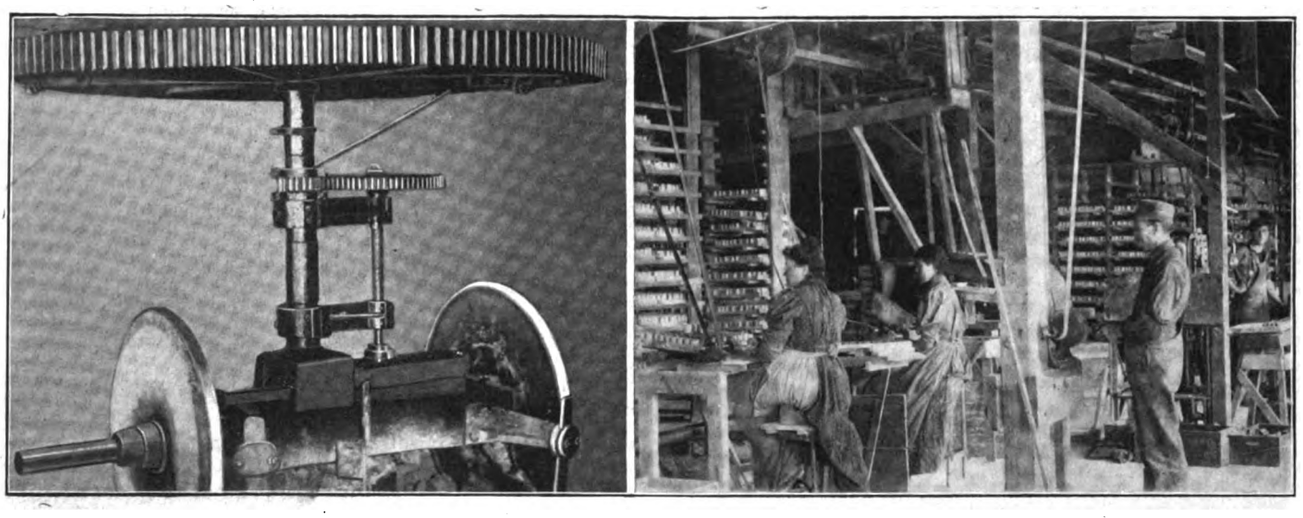
low figure and provide for the necessary number of turns on the armature to produce the required low speed.

The two circuit winding is used in every case where possible, as this allows the use of larger wire and fewer turns, which not only makes the coils simpler and cheaper, but allows a greater weight of copper, due to the fact that less room is taken up by insulation. Aside from this in the two circuit winding each pole has only a fractional influence on the total e. m. f. generated, and consequently any eccentricity of the shaft with reference to the bore of the field, or any inequality of some of the field windings which would produce an unbalanced field, would not disturb seriously the electrical balance of the armature. The fact that as few as two sets of brushes can be used with this type of winding on machines of low speed and small output is an additional advantage.

Carbon brushes in reaction type holders are generally used and are supported upon a special rigging, which is, in turn, supported by brackets attached to the field ring. As these motors do not require any shifting of brushes from no load to full load, no elaborate device is provided for shifting or lifting brushes from commutator. The machines are made by the B. F. Sturtevant Company, Boston, Mass.

## PORCELAIN AND CLAY INSULATORS.

The making of porcelain is one of the oldest arts that has come down from prehistoric time. For many ages it was regarded as a lost art, but modern ingenuity has solved the mystery and to-day the making of porcelain wares for both table and ornamental purposes, as well as for electrical uses, is a growing business in this country. Not only porcelain, but some grades of native clay are suitable for insulating purposes, the latter being almost as valuable as the former, in fact, fully as good in insulating properties, but not so attractive in appearance.



One of the extensive manufacturers of this class of goods is the Akron Smoking Pipe Company, whose works are located at Mogadore, Ohio. This company has control of clay deposits which are particularly adapted to the manufacture of insulating appliances, including special devices, such as switch bases, lamp socket parts or other forms which are designed to serve as non-conductors of electricity. The output includes tubes, ranging from 5/16 inches inside diameter to 2½ inches, and in length from 1 to 36 inches, as well as special shapes.

In the process of manufacture the clays are prepared by a washing process which removes all the foreign matter, including the iron oxides which are found in most clays and detrimental to the insulating qualities. After being washed the material is placed in what is known as a wet pan, which consists of a circular bed plate of iron with heavy wheels or mullers revolving upon it, and in this the material is pulverized and tempered until it receives adhesive qualities sufficient for molecular action to take place. It is now ready for the moulding process and is formed in dies or presses into electrical devices of all conceivable shapes and designs.

The forms after they are moulded are carefully placed on trays or dryers and placed on racks in the steam drying department, where they remain until all the moisture is evaporated, when the pieces are carefuly inspected or trimmed and finished and are passed on to the glazing department. After the pieces have been immersed in the glazing solution they are again dried and packed in seggers and made ready for the firing process. The seggers are cylindrical shaped forms, which are made in the works from the best of fire clay, and are manufactured on a pottery wheel, such as is employed for making ordinary stone ware. The object of their use is to protect the goods from the action of the flame in the process of baking, and being filled they are placed in tiers in kilns until they occupy the entire space.

The process of firing requires about seventy hours, during which time the contents of the kiln are raised to a heat of about 3600° F. This process fuses the silicates into the pores of the clay and also the glazing material, while it changes the chemical composition and produces the most durable substance known or found in nature. The kiln goes through a slow cooling process after the fires are withdrawn and the goods are not removed until the temperature is again normal.

It is a practice with the company to have samples of its goods frequently tested by the electricians of the Board of Fire Underwriters, and its cheapest grades of clays have stood the tests of immersion in water for 100 hours without absorbing more than 73/1000 of their weight of moisture. This, as will be noted, is well within the limit of 1 per cent., the limit allowed by the Board of Fire Underwriters.

SCENES IN THE MAKING OF PORCELAIN AND CLAY INSULATORS.

# New Apparatus and Appliances

### AN INGENIOUS LOCKING DEVICE FOR MOTOR CONTROLLERS.

To provide a simple locking and releasing device for motor controllers which should hold the rheostat arm at any point, the Chicago Rheostat Company, Chicago, Ill., has designed the arrangement shown in Fig. 1. The releasing device consists

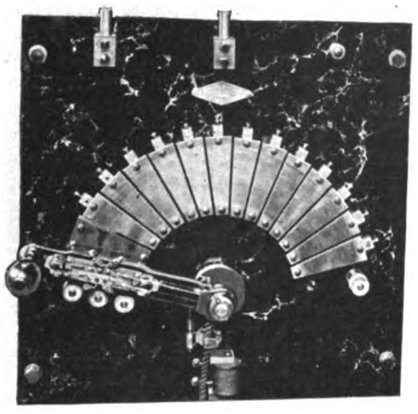

FIG. 1.—A MOTOR STARTER, WITH IMPROVED RELEASING DEVICE.

simply of a strap brake made up of a band of steel surrounding a small flange forming a part of the rheostat handle, one end of the band being fixed and the other attached to the armature of the releasing magnet. The latter, when energized, pulls up the strap of steel, gripping the pulley tightly and preventing the rheostat arm from turning toward the off position. When the voltage falls below a certain limit the magnet releases the armature and a small motion of the latter loosens the brake, leaving the rheostat arm free to respond to the spring, forcing it to the off position. The adjustment is such that the handle may be readily moved backward or forward over the contacts and yet is held firmly clamped on any desired contact, and resists successfully all jarring or vibrations tending to cause it to move from its position.

### A SIMPLE FORM OF LINE DISCHARGER.

For the protection of overhead lines the Stanley Electric Manufacturing Company, Pittsfield, Mass., has brought out a new type of discharger shown in Fig. 2. This consists of a spark gap which appears in the lower right hand side of the illustration, connected in series with a number of glass tubes filled with small metal balls about the size of bird shot. The resistance of these to ordinary voltages is very high, something over 50 megohms, but the disruptive discharges of lightning readily break across the contacts between the metal shot, much as do oscillatory currents across the contacts of a coherer, finding a ready path to ground, which, however, retains its resistance against ordinary pressures.

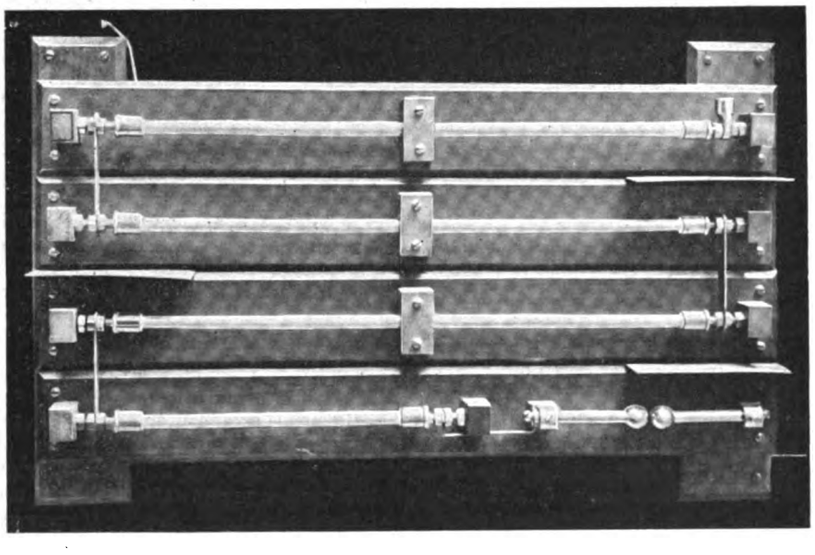

FIG. 2.—A LIGHTNING DISCHARGER FOR LINE USE

### THE HOYT DISCOUNT METER.

An indicator for giving the record of the maximum amount of current which has passed through it since its last setting, this purpose being the same as that of the Wright demand meter, is shown in Fig. 3. Unlike the Wright instrument, in which the indication is the result of the heating effect of the current, the Hoyt instrument is magnetic and mechanical in character.. A solenoid, which appears in the illustration just above the scale and below the wheel, attracts downwardly a plunger attached to a fine cord which passes around a drum fixed to the spindle of the wheel and index finger shown. From the right hand side of the periphery of the wheel another cord supports the piston of a dash pot, which piston also serves as a counterweight and force against which the magnetism set up by the solenoid must draw the plunger. The wheel is also fitted with a fine ratchet which engages with a light spring, serving as a pawl, which tends to hold it in the lowest position assumed by the plunger. When current passes through the instrument it draws down the plunger against the force of gravity on the dash pot piston, the deflection being proportional to the current. The apparatus is held at its point of maximum deflection by the ratchet, and sudden impulses of current are prevented from affecting it by means of the dash pot.

The meter is made by the Whitney Electrical Instrument Company, Penacook, N. H., under the patents of Mr. A. H. Hoyt, the company's general manager.

### PETITE ALTERNATING ARC LAMP.

The latest enclosed arc for alternating current circuits is that, one form of which

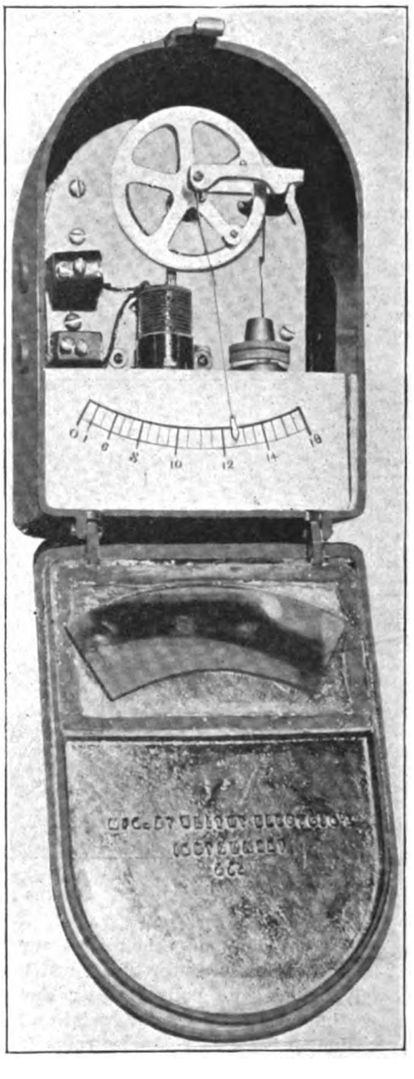

FIG. 3.—A MAXIMUM DEMAND METER.

is shown in Fig. 5, made by the Western Electric Company. The design of the lamp embodies several radical peculiarities. One of the most interesting of these is the regulating mechanism. All previous lamps, with one or two exceptions, employ an alternating current magnet or solenoid, which draws up an armature or plunger when the current through the lamp be-

Digitized by Google

comes greater than normal and allows the armature or plunger to fall away when the current becomes less than normal. The inherent difficulty with such

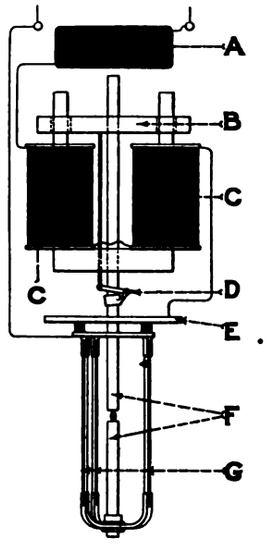

FIG. 4.—DIAGRAM OF PARTS OF PETITE ARC LAMP.

lamps, no matter what the shaping of the magnetic circuit may be, is the fact that the reluctance of the circuit becomes less when the armature is drawn in close to the cores or the plunger is drawn into the solenoid so that it requires a considerable fall of the current before the armature or plunger may be retracted, after which the reluctance is reduced and a considerable rise of the current must occur before they will be again drawn in.

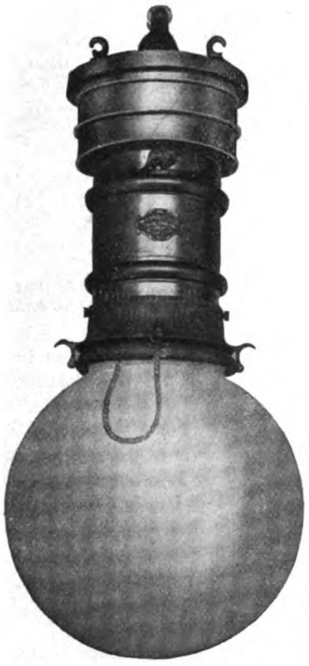

FIG. 5.—THE PETITE ARC LAMP.

The regulating mechanism of the Petite arc lamp is magnetic in character, but instead of the attraction of a magnet for an armature it utilizes the repulsion of an alternating current magnet for a short-circuited secondary. The principle of its operation is shown in Fig. 4, where B is an armature of aluminum, surrounding the upper ends of the cores of the magnet, C, and attached to the clutch shown, which grasps the upper carbon. The repulsion is obtained by means of the currents generated in the aluminum of the armature, which tend to force the latter upward, lifting the carbon with it. The upward motion allows the magnetism to leak away below the armature, keeping the armature in a stable suspension over a considerable range of motion with a small range of current.

Another detail of interest is the return circuit from the lower carbon. This is divided and passes up through the three side rods or supports, G, spaced at equal radial distances around the arc, so that the magnetic effect of the current on the arc is eliminated and the arc does not tend to burn out on one side of the carbons and flame, as it does in some lamps where the current passes up entirely at one side of the arc. The lamp is provided with a choking coil, A, with a ring-shaped magnetic circuit, the windings being tapped out with various terminals for different voltages and the two standard frequencies. The contact with the upper carbon is obtained by means of a clamp at its upper end connected through a flexible cord. An air dash pot is used to prevent too abrupt movements of the parts.

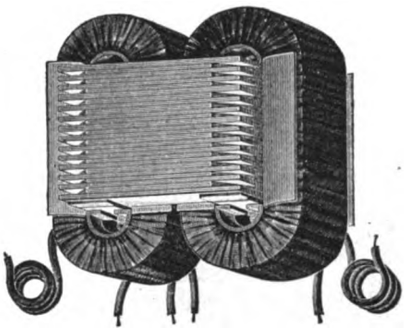

FIG. 6.—AN IMPROVEMENT IN TRANSFORMER CORE CONSTRUCTION.

The lamp is made in various styles, with inner and outer globes or with inner globes and reflecting shades, as well as in a marine type. A hood is provided for out-of-doors service.

### IMPROVEMENTS IN THE SCHEEFFER TRANSFORMERS.

Transformer construction has reached such an advanced stage that further advances are only in the refinement of details. An advance of this kind, simple in character, but for that reason all the more valuable, is embodied in the most recent types of transformers built by the Diamond Meter Company, Peoria, Illinois.

The appearance of the coils and core of this transformer is shown in Fig. 6, the improvement referred to being the arrangement of the corners of the stampings. In a rectangular magnetic circuit the lines of force make but little use of the outside corners of the laminae, rounding the inside corners by shorter paths. Some manufacturers cut the outside corners away and others leave them in place. In the Scheeffer transformer half of them are cut away and the laminae are assembled in bunches, with full and cut-away corners alternating, leaving slots across the corners, such as are clearly shown in the illustration. In this way the radiating surface of the core is considerably increased without the removal of any valuable iron, and hence without increasing the density at any point. The transformer bears other evidences of careful design, notably the semi-circular forms about which the coils are bent, preventing any cutting of the coils on sharp corners.

The improvement in the core structure described is the invention of Mr. G. A. Scheeffer, covered by patent No. 627,144, recently issued.

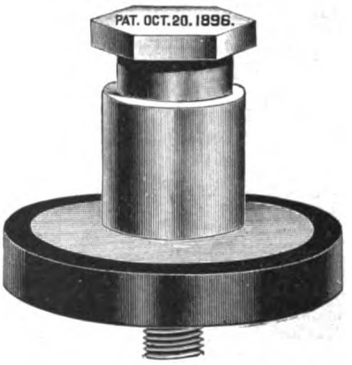

FIG. 7.—PERSPECTIVE VIEW OF PUMP VALVE.

### THE PARKER PUMP VALVE STEM.

An improved form of stem for pump valves is shown in perspective in Fig. 7 and in section in Fig. 8. The latter illustration shows clearly the features which characterize this stem and render it an improvement on older forms. The use of an upper guide, as well as a lower, insures a more accurate alignment and square seating of the valve and reduces the wear, which otherwise causes the hole in the valve to get out of shape or become enlarged. The spring is encased in its own chamber. Broken pieces of the spring cannot get through the pump to damage packing or other parts. After one side of the valve is worn it can be reversed, thus get-

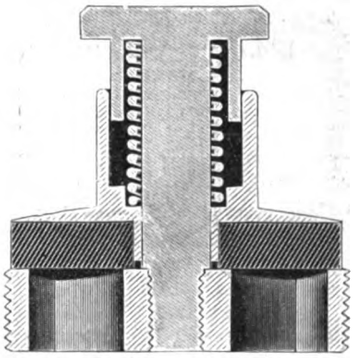

FIG. 8.—SECTION OF PUMP VALVE.

Digitized by Google

ting double wear. It is claimed that the valves seat more promptly, reducing slippage and saving the steam.

This valve stem is manufactured by Jas. McCrea & Company, Chicago, Illinois, in connection with their older product, the Climax steam clamp joint. The pump stem has already come into quite wide use, over 3500 of them being used by the Standard Oil Company at one plant.

### METALLIC GASKETS FOR GENERAL PACKING PURPOSES.

In Figs. 9 and 10 are shown two forms of a metallic gasket, an improvement over the old leather and rubber article, for ren-

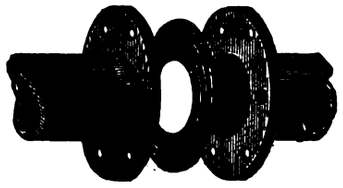

FIG. 9. METALLIC FLANGE JOINT GASKET.

dering steam-tight the flange connections of steam piping, as well as many other bolted joints subjected to fluid pressures. The illustrations show two different patterns of the metallic gasket, which consists of thin sheet copper stamped with concentric currugations. Three to six corrugations answer as well as more, the space available within the bolt holes determining the width of the gasket. Connections made by the use of this improved article are not affected by heat and pressure in such a way as to be blown out after continued use, for each corrugation makes the entire circle of the flange, and so long as the contact is kept complete by compression the joint cannot leak. This style of gasket is naturally not impaired by the repeated expansion and contraction of steam pipes, as its springy nature allows it to follow changes of its bounding surfaces. It is, therefore, of particular value on pipes in which steam is used intermittently. In cost these goods compare favorably with other gaskets now upon the market, and as they are furnished to steam users the exact size re-

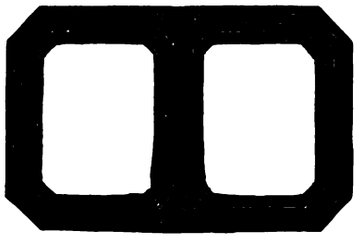

FIG. 10.—METALLIC GASKET FOR RECTANGULAR JOINT.

quired to make a tight joint, there is no surplus material to be paid for.

Aside from the circular and square patterns here illustrated, the manufacturers have also oval, rectangular and irregular shapes for steam chests and cylinders of engines and pumps. Their line embraces lip union, flange union, plain and ball joint gaskets for carrying water, steam, air and gas. Parties desiring to give the goods a trial on any leaking joints may have samples upon application to the U. S. Mineral Wool Company, 2 Cortlandt Street, New York City, or the Bourne & Knowles Manufacturing Company, Cleveland, O.

### AN INTERNAL SELF OILING AUTOMATIC STEAM ENGINE.

The distinctive feature of this new design of engine, put on the market by the Ball Engine Company, is the automatic oiling system.

It will be seen by the sectional view, Fig. 11, that the oil is contained in a pocket in the bottom of the frame. The crank discs in revolving carry over a portion of this oil into a trough in the top of the frame, covered in by the hood. Thence the oil flows in streams into the main bearings, and is also carried by the radial holes to the crank pin.

There are removable guiding plates, one on each side of the connecting rod at the ends of the guides next to the crank discs, so arranged that they make a slot through which the oil is guided directly into the crosshead, which has a large bell-shaped opening to receive it.

As the guiding plates guide the oil directly into the crosshead, the doors on the side of the frame may be taken away for the purpose of taking indicator cards or for examination of the crosshead, without the oil being thrown on the engineer or on the floor.

Another important feature in connection with the oiling device is the dividing wall between the cylinder-head and the crosshead chamber of the frame. By means of this the oil is kept cool and the water of condensation from the piston rod stuffing box is prevented from mixing with the oil in the frame, while access to the piston-rod stuffing box is gained by openings in the frame between the division wall and the cylinder head, as shown.

In the front or crank end of the engine will be seen a hand hole closed by a plate screwed in. By unscrewing the plate access may be gained to the crank-pin boxes for adjustment. This obviates the necessity of removing the hood.

The hood, which is made of cast-iron corrugated, is fitted absolutely oil tight and rests in a groove without fastenings of any kind, and therefore may be readily removed, exposing the discs and crank end of the connecting rod.

The connecting rod and straps are forged from steel blooms. The adjustments are by means of wedges operated by T-pointed set-screws, which move the wedges up or down. As the movement of the wedges is in the same direction, the length of the rod is not altered, nor is the position of the piston changed.

The crank-shaft is a single forging of open-hearth steel, containing the proper amount of carbon to give strength and durability, and ground to an accurate, smooth-running surface. Cast-iron discs are secured to the shaft by keys in such a manner as to prevent their getting loose or impairing the strength of the shaft.

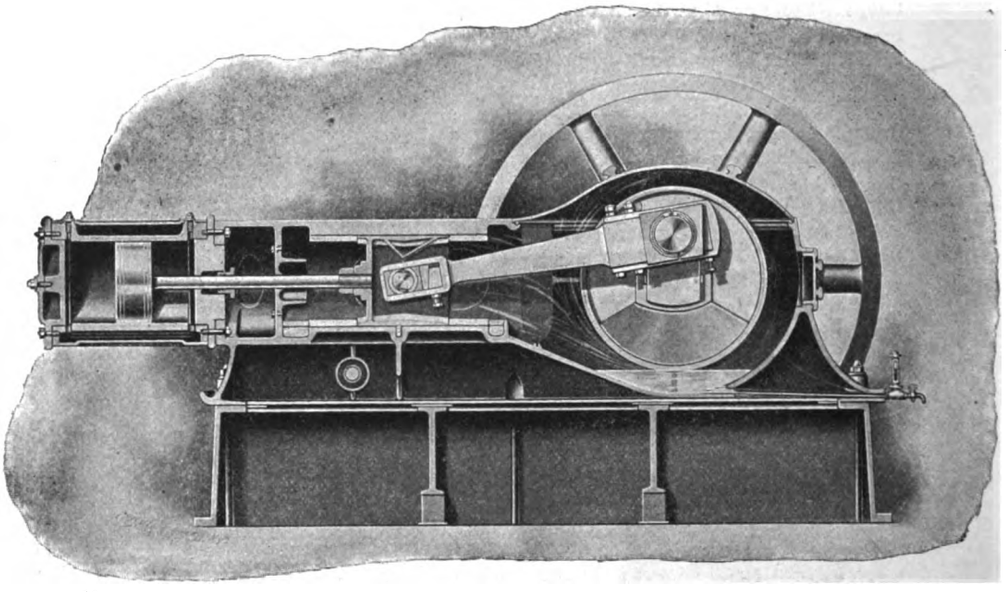

FIG. 11.—SECTION SHOWING CONSTRUCTION AND OILING ARRANGEMENTS OF BALL ENGINE.

The introduction of the shaft into the engine is accomplished by arranging the shaft boxes (which are entirely separate from the frame) in a jaw cutting into the bed deep enough to bring the center of the shaft in a plane with the center line of the engine, finished spots being provided to meet corresponding finished surfaces on the boxes.

A new and desirable feature is the self-oiling eccentric and strap. The straps are designed with a reservoir at the bottom containing oil, and by an arrangement of flanges and grooves the oil circulates around the eccentric while in motion, and only requires to be renewed at long intervals.

Digitized by Google

THE LEFFEL "CLASS B" ENGINES.

The accompanying illustrations represent the class "B" standard center crank automatic cut-off engines being put on the market by James Leffel & Co., Springfield, Ohio. They are intended to meet

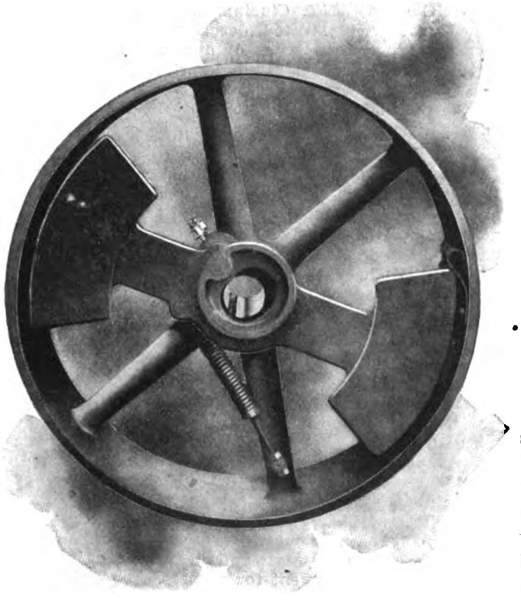

FIG. 12.—VIEW SHOWING GOVERNOR IN BAND FLY WHEEL.

the demand for a thoroughly good, simple and easily cared for line of automatic engines in the smaller sizes up to 50 h. p., that will prove durable and economical in operation. Fig. 13 is a view showing steam chest side, and Fig. 12 illustrates the governor in the band fly wheel.

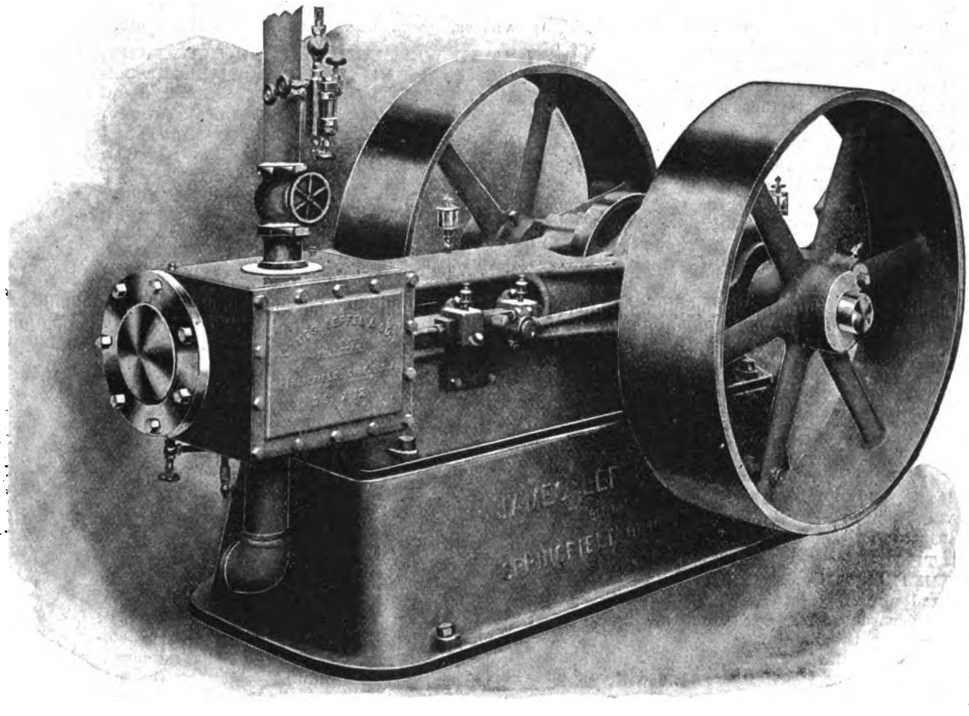

FIG. 13.—VIEW SHOWING STEAM CHEST SIDE OF ENGINE.

The main frame or bed is of substantial proportions, and of a design affording extra strength and stiffness. The cylinder and steam chest are of the overhanging type, cast together, and firmly bolted to bed. The cross-head guides are a part of bed, bored out, and have very generous surfaces. The cross-head is of improved mechanical design, having pin about mid-center, and provided with gun metal wedge-shaped shoes above and below, arranged for convenient adjustment. The manner of fitting cross-head pin enables it to be easily kept absolutely tight at all times. The piston rod is of steel, and turned to a tight force fit in the piston, with a suitable shoulder, against which the piston is forced on rod, the end of latter being then securely riveted over, tightly and firmly holding the piston in place.

The connecting rod is provided with extra heavy brass boxes at each end, easily adjustable for taking up wear and keeping distance between centers same at all times. The main shaft is extra large and strong, forged in one solid piece, from best quality hammered iron or steel, and is provided with suitable counter balance discs, securely attached. The rectangular form of skeleton slide valve is used, balanced by being fitted with a pressure-relieving plate on back between valve and steam chest lid, and is arranged to afford necessary relief in case of water in cylinder, and is also made adjustable for wear. This gives a simple, efficient and well balanced valve, that is easily understood, and no more trouble to care for than the ordinary type of plain slide valve. A simple and convenient device (not shown in cuts) is provided for draining the cylinder, same being operated by one lever, and having outlet from each cylinder cock suitably connected to exhaust pipe.

These engines are equipped with the Rite's governing system, which is the acme of simplicity, as shown in Fig. 12. The governor consists of one piece, comprising the arms and weights, with one spring connection, and is pivoted on one hardened steel pin—nothing complicated, no links, no numerous joints or complicated parts. This governor, with the balanced valve used, affords a regulation that is practically perfect, speed being constant, and the same with engine loaded or running empty.

## NEW BOOKS.

Diagrams and Handbook for Telegraph Engineers. By Willis H. Jones. New York: Pocket edition. The Telegraph Age; 115 pages. Price, $1.00.

This work consists of 47 sheets of diagrams, showing most plainly the connections of telegraph sets in the varied ways of modern practice. The diagrams are very clearly drawn, the different instruments being represented by pictorial figures which cannot be mistaken, and every part of the circuit is named, so that they are practically self-explanatory. These are supplemented by a number of useful tables, rules and other pieces of information.

The Indicator Handbook. By Chas. N. Pickworth. Part 1, the Indicator, Its Construction and Application. New York: D. Van Nostrand & Company. 126 pages, illustrated. Price, $1.50.

This work is a thorough, practical manual on the use and application of the indicator. Three chapters are devoted respectively to the construction of the indicator, of its attachments and of its reducing gear, and following each is a chapter devoted to the errors of the devices described, so that users may find complete data by which to obtain the most accurate results. The work is illustrated by carefully made drawings and wood cuts of ample size to show plainly the exact nature of the devices referred to. The author is editor of the "Mechanical World" and shows throughout the work complete familiarity with the subject discussed.

The Slide Rule. A Practical Manual by Chas. N. Pickworth. Fifth edition, revised and enlarged. New York: D. Van Nostrand & Company; 88 pages. Price, 80c.

The rewriting of this work, which has exhausted four editions in but little more than as many years, has allowed the introduction of considerable new matter, making it a thorough manual on slide-rule computation. Many constant users of the slide rule for simple work have no conception of the value such an instrument would have in their calculations were they capable of utilizing all its functions. The perusal of this manual, which is thoroughly practical in character, would prove of great value to them as well as to those who have not as yet taken up the use of the slide rule at all.

## OBITUARY.

MR. HERBERT H. BROOKS, for the past ten years General Manager of the American Circular Loom Company, Boston, Mass., died suddenly Sunday, July 9th, from lung trouble culminating in consumption. Mr. Brooks was very widely known to the supply men throughout the United States.

## LEGAL NOTES.

THE GENERAL ELECTRIC COMPANY'S RAILWAY PATENTS.—During the months of June and July the General Electric Company has obtained preliminary injunctions under the Van Depoele patent for suspended switches No. 424,695 against the Worcester & Clinton Street Railway Company and the Central Union Brass Company of St. Louis, Mo. Under the Condict patent No. 393,323, on series parallel controllers the company has obtained preliminary injunctions against the Worcester & Clinton Street Railway Company and the Mill Creek Valley Street Railway Company.

THE LEE INJECTOR MANUFACTURING COMPANY is the name of the successor to the Lee-Penberthy Manufacturing Company, manufacturers of the well-known Lee injector and other steam specialties. The change of name signifies no change of policy or interference with the manufacture and sale of Lee injectors, but is simply a result of a suit instituted by the Penberthy Injector Company to restrain the former Lee-Penberthy Manufacturing Company from using the name Penberthy in its corporate title. Mr. William O. Lee, Secretary and Manager of the new company, announces that it will push the construction and sale of the Lee injectors in future as well as in the past, and that Thos. J. Sweeney will be associated with the new company as mechanical expert.

THE TRUSTEE'S SALE OF THE DIAMOND ELECTRIC COMPANY.—On July 20th the accounts and miscellaneous assets of the Diamond Electric Company, formerly of Peoria, Illinois, were sold in bankruptcy proceedings in Chicago. The company became involved last Fall, parties holding judgments against them closing the factory, which was then sold by the United States Marshal in October. The plant was afterwards bought by the Diamond Meter Company, which now operates it, manufacturing Scheeffer transformers and integrating meters. No one connected with the new company was interested in the old with the exception of Mr. G. A. Scheeffer, who was the superintendent of the old, as he is of the new works. The remaining assets of the old company, chiefly unsettled accounts, were placed in the hands of an assignee and sold, as noted above, on July 20th.

## PERSONALS.

MR. G. F. GREENWOOD, consulting engineer of the Consolidated Traction Company, Pittsburgh, Pa., has been selected to be engineer in charge of the work of rebuilding and reconstructing the street car lines in Havana, Cuba. Mr. Greenwood will not commence his new duties until early in the fall.

MR. MARK A. REPLOGLE, well known for his work in the development of water wheel governors, and heretofore associated with the Replogle Governor Works of Akron, Ohio, has connected himself with the Webster, Camp & Lane Machine Company of the same city, which company will make a specialty of equipping water powers with wheels designed and controlled for accurate governing.

MR. G. H. CONDIT, the electrical engineer of the Electric Vehicle Company, has, since the consolidation of this company with the automobile department of the Pope Manufacturing Company, become the consulting engineer of the consolidated interests and has consequently moved to Hartford, Conn. Mr. Condit is well recognized as one of the foremost electrical automobile designers in this country, the development of the electric cabs and broughams now running in considerable numbers in New York City being largely from his designs, as is also the remarkable charging equipment for the same.

MR. HENRY HINE, the general manager of the Stanley Electric Manufacturing Company, has been appointed general manager of the Sprague Electric Company, and assumed office on July 12. This completes the new list of Sprague officers, consisting of A. B. Chandler, president of the Postal Telegraph Company, president; John E. Searles, first vice-president; Frank J. Sprague, second vice-president and technical director; and Henry Hine, general manager. Mr. Hine has been general manager of the Stanley Company for the past eight years, prior to which time he was connected with the Westinghouse and Sawyer-Man Companies, and has always been prominent in the electric manufacturing business. For the present, he will continue in the management of the Stanley Company as well as assuming similar functions with the Sprague Company.

HENRY S. WEBB, until the end of the college year just closing connected with the department of electrical engineering of Lehigh University under the direction of Prof. Franklin, has resigned from this position and accepted that recently vacated by Mr. Kempster B. Miller in the International Correspondence Schools, Scranton, Pa. Mr. Webb is well known to readers of the American Electrician through his contributions, particularly on the subject of telephony. His work with the International Schools will be instruction and preparation of text books on telephony and telegraphy. Mr. Webb is a young man, having graduated from the electrical engineering course of the Massachusetts Institute of Technology only seven years ago. His first work after leaving college was with the General Electric Company, where he spent about a year, after which he engaged for a short time in contracting engineering work in Cincinnati, since which time he has been connected with Lehigh University as noted above, having charge of some of the electrical laboratories and particularly of the telegraph and telephone instruction. Mr. Webb's ability to not only comprehend and keep posted upon the advances of electrical engineering, but also to make them clear to others, has been evident from his contributions to the electrical press. The management of the International Correspondence School has, in obtaining him, shown another instance of its good judgment in the selection of members of its staff of instructors.

## TRADE PUBLICATIONS.

THE C & C ELECTRIC COMPANY, New York City, has issued a new bulletin, No. 129, of its motors and controllers, succeeding several previous publications.

THE FAIRBANKS COMPANY, New York City, has issued a complete illustrated catalogue and price list of its asbestor disc valves, asbestos cocks, vulcabeston packing, injectors, traps, hydrants, service boxes, etc.

THE S. S. WHITE DENTAL MANUFACTURING COMPANY, New York City, has issued a pamphlet on the general subject of painless dentistry by means of cataphoresis, outlining the medical value of this application of the electric current and describing the apparatus therefor.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., has published a 40 page pamphlet on "Brazing by Immersion." The Dixon company makes crucibles especially designed for this process, as well as anti-flux brazing graphite which prevents the brass or spelter from sticking to the metal.

THE AMERICAN STEEL & WIRE COMPANY, the merger company which has absorbed the wire making industries of this country, had representatives at the Independent Telephone Association convention at Chicago, who distributed the thirteenth annual edition of the pocket hand-book on iron and copper wire, as published by the Washburn & Moen Manufacturing Company.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, Ohio, has issued a new illustrated descriptive catalogue of its various types of dynamos and motors, including illustrated descriptions of the Bullock system for operating web presses, the controlling panels made by the company for press driving motors and the company's new magnetic blow-out controller.

THE B. F. STURTEVANT COMPANY, Boston, Mass., is distributing a novelty in advertising literature entitled "2500 Witnesses," which consists of a 48-page list of users of Sturtevant ventilating and heating apparatus. The list is classified so that any one who contemplates the purchase of such apparatus may immediately find a list of others in his own line of business who are using Sturtevant equipments.

THE CROCKER-WHEELER ELECTRIC COMPANY, Ampere, N. J., has taken up in its Publication Bureau the different industries in which Crocker-Wheeler machines may be used, and is publishing special pamphlets for each; one entitled "Electricity for Printers" has recently been sent out to publishing establishments, pointing out the ease of control, efficiency, increased output, flexibility, decreased waste and cleanliness of motor driving equipment for presses.

THE MASON REGULATOR COMPANY, Boston, Mass., has published a convenient catalogue of some 40 pages of the steam specialties for which it has become famous. The exact nature of each device is thoroughly made clear by cross sections of the instrument with accompanying explanations. Central station engineers will therefore find the catalogue—even if they have no immediate need for any apparatus described therein—an interesting and instructive work on valves, governors, damper regulators, etc.

THE WESTERN ELECTRIC COMPANY, Chicago and New York, has published a bulletin, No. 9001, describing the Facil hand register and other accessories of the system of police and fire alarm invented by and named after City Electrician Ellicott of Chicago. The bulletin illustrates and describes a battery of 8 machines used as motor generators in the City Hall, Chicago, put in originally to carry the police and fire alarm lines while the storage battery was being charged. The machines were started up over 4 months ago and it has not been found necessary as yet to put the storage battery again in circuit.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa., has described in a bulletin the equipment of chloride accumulators in the Dun Building. The chief peculiarity of this equipment is the location of the battery, which is in a light fireproof structure on the roof, giving it ample room and light and ideal ventilation with no danger of fumes in the building. The battery has a capacity of 720 ampere hours at a one-hour discharge rate, and serves the triple purpose of smoothing the load curve on the generators, steadying the voltage and providing an emergency or night source of current for the lighting and electric elevators. Owing to the fact that the generators are run at constant load, the fluctuations being taken by the battery, the coal consumption has been found to be reduced 25 per cent. below that with the battery out of service. The building is owned by the well-known house of R. G. Dun & Company, for whom nothing is too good, and the electrical equipment consists throughout of the finest available apparatus.

Digitized by Google

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has issued two new bulletins, one on its type "C" polyphase induction motors for constant speed and the other on its central station transformers and transformer fuse blocks. The former illustrates the latest types of induction motors up to and including the 500 h. p. size, which is the largest of this type built by this company. The other bulletin describes the well-known Westinghouse transformer with the peculiar open ventilated housing designed for interior work, which allows the atmosphere an open circulation around the windings and core of the transformer.

THE PEERLESS RUBBER MANUFACTURING COMPANY, New York City, has distributed a highly colored poster representing pictorially a brownie scene, entitled "The Brainies hold an engineering contest." A comparison of the two pictures shown, one showing the trouble given by an engine on which is used "just as good packing," and the other the running of an engine packed with Rainbow packing, emphasizes the conclusion that the latter is the life of the driving power of machinery. The company offers a reward of $25 for evidence of the substitution of other packing on orders for Rainbow, with the improper use of the name or its abbreviation, Rbw.

THE WARD-LEONARD ELECTRIC COMPANY, Bronxville, N. Y., has published a catalogue, No. 996, listing enamel field rheostats of the Carpenter type. These are designed with what is called a "2 to 1 taper in ampere capacity," this expression meaning that the ampere capacity of the different steps of the rheostats is tapered so that the carrying capacity at the maximum current end is twice that at the minimum current or maximum resistance end, in addition to which the resistance of the different steps is varied inversely as the square of the amperes. The catalogue advises users that good results will be obtained by using rheostats the resistance of which is about equal to that of the field to be regulated.

A SYSTEM OF ENGINES is the title of one of the most interesting and complete catalogues of any engine building house ever published. It describes the various engines built by the Harris Foundry & Machine Works, Harrisburg, Pa. As engine users have already learned, these works do not attempt to specify one type of engine for the many different uses where steam power is needed, but make engines of four general types, each of which is made in several different styles, simple, tandem or cross-compound, etc., and of a large range of sizes. This makes a total of 22 styles of engines, ranging in size from 6 to 300 h. p. capacity. The 4 general types are the Ideal, the Harrisburg Standard Single Valve, the Harrisburg Standard Four Valve and the Harrisburg Corliss. The catalogue has been published in two editions, one on coated paper to show the handsome half-tone illustrations and with the ordinary paper cover, and the other an edition de luxe printed on rough hand-made paper with deckel edge and with a library binding of half morocco. The illustrations in this edition are on artists' proof sheets, separately bound in. As a work of fine book making it is propably unsurpassed in trade literature. The company announces that it has been running day and night for the past ten months and has refused, owing to the crowded condition of its establishment, many otherwise attractive contracts. It is at present having work done in its four separate establishments to keep up with the contracts on hand, while its present output is three times greater than that of 1897.

WIRT RHEOSTATS AND THEATRE DIMMERS are described in a bulletin issued by Chas. Wirt & Company, Philadelphia, Pa., consisting of advance sheets of a new catalogue to be published. Among the good points brought out about these rheostats are the facts that they are completely encased in cast iron, affording ample protection and a good radiating material; there are a large number of steps, no rheostats having less than fifty; the commutator is protected against injury by being placed below the surface level and is made of phosphor bronze; there are no small parts, such as pins, nuts, etc.; the insulation used is mica, capable of withstanding sudden changes of temperature and consequent changes of volume without cracking; and the resistance is a continuous metallic ribbon, containing no contacts liable to break joint. The rheostats are rated in two different ways, one for loads to give a rise of temperature not over 100° F. above surroundings and the other not over 200° F. The first has one watt per sq. in. and the second three watts per sq. in. of cooling area. The theatre dimmers are made in a large number of styles to suit different demands, one convenient form for a main dimmer being made with a vertical shaft, to which plates may be added in any number below the floor, the hand wheel being above. They are also made with pairs of plates for the three-wire system and in the larger sizes with interlocking switches, enabling two or more banks of lights to be controlled together. A dimmer is often called upon to work with much less than its full load. In this case most of the dimming will be done upon the last few steps of resistance cut in, and unless the dimmer has a large number of steps the jumps on these last few contacts will be perceptible. For this reason no Wirt dimmer has less than 50 steps, no matter how small its size.

## BUSINESS NEWS.

THE CENTRAL ELECTRIC COMPANY, CHICAGO, as selling agent, reports that it is gaining many orders for Columbia lamps.

THE OREGON TELEPHONE AND TELEGRAPH COMPANY has recently laid a six-conductor cable, 4725 ft. long, under the Columbia River at Vancouver, Washington.

THE AUSTIN STEAM AND OIL SEPARATOR is reported by the manufacturers, the Austin Separator Company, Detroit, Mich., to be meeting a large foreign demand.

THE KENNEDY VALVE MANUFACTURING COMPANY, at Coxsackie, N. Y., is planning improvements and additions to its plant. The additions are a two-story building, 45 x 120 feet, for offices and machine shops, also a foundry addition of 25 x 75 feet, and the installation of a new 125 h. p. engine.

TROTTER'S MONA COMMUTATOR COMPOUND, as made by Trotter's Mona Manufacturing Company, is a most efficient lubricator for either carbon or copper brushes. A sample will be sent free to any one who wishes to give it a trial and will send his address to Messrs. Goldmark & Wallace, New York City.

MESSRS. SEMPLE BROTHERS, Pittsburgh, Pa., will hereafter manufacture black varnishes by the processes heretofore used by the Sterling Varnish Company of the same city. The latter company will temporarily cease the manufacture of these products owing to press of business in other directions, and its trade in these lines will be turned over to the new makers.

EUREKA PACKING was, during the recent war, carried in the storeroom of every vessel in the United States Navy, according to the statement of the makers, Jas. L. Robertson & Sons, New York City. The demand for it has grown to such an extent that imitations have been put on the market, and users are requested to look for the red diamond-shaped label on every box and also on every two feet of packing.

THE RUMSEY ELECTRICAL MANUFACTURING COMPANY, Philadelphia, Pa., has been appointed Eastern sales agent for the Pittsburgh Transformer Company, its territory including Eastern Pennsylvania, Southern New Jersey, Delaware, Maryland, West Virginia and Virginia. This company is well known and popular among the trade, deservedly so on account of its careful and conscientious business methods.

MESSRS. SHEEHAN & HEWITT, Newburgh, N. Y., electrical engineers, contractors and builders of switchboard and other appartus, have dissolved partnership, Mr. W. M. Sheehan retiring from the firm. Mr. Chas. E. Hewitt has formed a co-partnership with Mr. H. A. Warden, the firm to be known as Hewitt & Warden and to carry on the business previously conducted by Sheehan & Hewitt.

THE STANDARD UNDERGROUND CABLE COMPANY, Pittsburgh, Pa., intends to benefit from the contemporaneous policy of expansion of the United States Government by taking up the manufacture of deep sea cables. The company hopes to secure the contract for the cable which is to connect the Hawaiian Islands with San Francisco. The firm's representatives have examined several sites on the eastern seaboard for the location of a station where the cable can be loaded aboard ship.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, Ohio, announces that the combination of prosperous times with the record the company has established for high-grade electrical machinery has developed such a demand for its apparatus that its new factory—with three times the capacity of the former works—is overtaxed to meet the demand created by its sales department. The difficulty will soon be remedied by a further increase of manufacturing facilities.

THE AMERICAN ELECTRIC TELEPHONE COMPANY has moved into a new building, 38-50 Jackson Boulevard, corner Canal Street, Chicago, Ill. The change in quarters was made necessary by the company's rapidly increasing business, which it reports has quadrupled during the last year. The new building is a modern eight-story structure, which has been equipped with the latest automatic machinery, making it one of the largest and finest telephone manufacturing establishments in the world.

THE H. C. ROBERTS ELECTRICAL SUPPLY COMPANY, Philadelphia, reports a steady increase in the demand for its products, among the recent sales of trolley and feeder wire being large quantities to the interurban electric railway from Dayton to Xenia, O.; the Schuylkill Valley Electric Railway Company, of Pottsville, Pa., and the Norfolk Terminal Company, Norfolk, Va. The company's wire has also been shipped to Lewiston, Pa.; Cincinnati, O.; Rising Sun, Ind., and numerous other places.

MR. H. R. WELLMAN, who has been the electrical engineer of the Armitage-Herschell Company, N. Tonawanda, New York, for some three years, resigned on July 10th to accept a similar position with the General Incandescent Arc Light Company of New York City. Mr. Wellman has done no small amount of difficult and original work with the Armitage-Herschell Company, notably in the design of dynamos and motors, and particularly of motors and controlling apparatus for electric elevator service, one of the most difficult fields of design, his success in which evidences his ability in the laying out of electrical machinery.

THE HOPPES MANUFACTURING COMPANY, Springfield, Ohio, has received the following repeat orders, in addition to those mentioned in the last issue of the American Electrician, which furnish additional evidence, if any were needed, of the satisfaction which its apparatus has given: The Kelly Axe Manufacturing Co., Alexandria, Ind., 400 h. p. live steam feed water purifier, and 400 h. p. exhaust steam feed water heater: The E. L. McClain Manufacturing Co., Greenfield, Ohio., 400 h. p. purifier, and 350 h. p.

Digitized by Google

heater; The South Dakota Hospietal, Yankton, S. D., 200 h. p. purifier, and 400 h. p. exhaust steam feed water heater.

THE RENEWAL OF ACTIVITY AT THE FORT WAYNE WORKS.—Since the sale of the property of the Fort Wayne Electric Corporation to the General Electric Company the works at Fort Wayne, Indiana, have renewed their former air of bustle and activity. They are now running full time with a large addition to the number of men employed. The department devoted to the construction of Duncan meters has been active throughout the corporation's troubles and is now turning out meters at the rate of 600 per week. A new laboratory has been equipped for testing these meters. The works are in charge of Mr. J. J. Wood, of arc light fame, Mr. F. S. Hunting being the new Sales Manager.

PROSPECTS OF THE SIEMENS & HALSKE ELECTRIC COMPANY OF AMERICA.—The announcement that this company had been purchased by the Electric Vehicle Company has been the occasion of the idea that the Siemens & Halske Company would give up the manufacture of the lines of machinery which it has been building hitherto and devote its entire equipment to automobile work. Mr. C. S. Knight, Vice-President of the Siemens & Halske Company announces that this is not the case and that the only effect of the change of ownership will be the extension of the previous lines into new fields, notably the construction of arc and alternating as well as direct current and multiphase apparatus.

MR. JOHN S. NOWOTNY, Cincinnati, O., announces that he severed his connection with the Nowotny Electric Company March 31, 1898. Mr. Nowotny founded the Nowotny Electric Company and managed the business from its start until March 31, 1898. The assignment of the company, which occurred June 30, 1899, in no way affects him. After severing his connection with the above-named company, he immediately embarked in the manufacture of Nowotny's semi-vacuum long burning arc lamps and electrical specialties. The latter named business is owned solely by him and operated under his personal supervision and name, and is in no wise connected with the Nowotny Electric Company, which has made an assignment as noted above.

THE CLING-SURFACE MANUFACTURING COMPANY, Buffalo, N. Y., reports rapidly increasing sales, not only in this country but from Australia, Europe and South America. These, with a fast growing business in Mexico, go to prove that the truth of the oft-repeated phrase, "The days of tight belts are over," is appreciated by belt users. A recent letter from the engineer of Brown, Durrell & Company, Boston, voices the general verdict: "Having tried Cling-Surface on my 12 in. dynamo belt, I have been able to carry full load with 22 in. sag on the belt with no perceptible slip. It surpasses my expectations, and I can cheerfully recommend it to do all that is claimed for it if directions are followed."

THE RIKER ELECTRIC VEHICLE COMPANY has been incorporated under the laws of New Jersey, with a capital of $2,000,000, six per cent. non-cumulative preferred and $5,000,000 common stock. The company will purchase for cash all patents, machinery, contracts and rights of Andrew L. Riker and the Riker Electric Motor Company for the manufacture of electric vehicles. It will purchase extensive works at Elizabethport, N. J., which have a present capacity of five complete vehicles per day. Among those interested in the company are Andrew L. Riker, Charles A. Lieb, President of the Great Falls Power Company, of Washington; O. T. Crosby, of the Washington street railways, and F. C. Stevens, President of the West End Bank, Washington.

THE JOHN A. ROEBLING'S SONS COMPANY, of New York, was incorporated at Albany, N. Y., on May 25, with a capital of $100,000, to manufacture and deal in wire, wire rope, iron, steel, copper and all other metals and other materials used in connection with them, and to contract for building structures of such material and metals. The directors are: Washington A. Roebling, Charles G. Roebling, Jr., Frank O. Briggs, Charles G. Roebling and Ferdinand W. Roebling, of Trenton, N. J., and Henry L. Shippy and Edmund Roebling, of New York City. The company is controlled by the same people as the original New Jersey corporation, the company having been incorporated in New York State for convenience in doing business.

MR. F. C. SUTTER of the Pittsburgh Transformer Company, Pittsburgh, Pa., visited New York July 10th to 12th, his special mission being to obtain an agency for his company's apparatus in New York and New England. Mr. Sutter was fortunate in obtaining the Western Electric Company, who will hereafter handle the Pittsburgh "type K" transformer in these districts. Mr. Sutter stated that the Pittsburgh Transformer Company has found no summer season this year in its business, its orders increasing regularly month after month. The company has been obliged to put in new machinery as fast as possible to handle the growing trade. One large source of business is the active work of the Rumsey Electrical Manufacturers' Company, which is making exceptionally large sales in Philadelphia and adjoining territory, considering the fact that it is the summer season.

MR. E. V. BAILLARD, engaged in the business of machine construction and model making, has recently added extensively to his quarters at 106 Liberty Street, New York City, the extension practically tripling the former floor space. The new space is required for the addition of machine tools and other apparatus required by Mr. Baillard's growing business, which will be supplemented by more complete electrical testing instruments, rheostats, motors and other apparatus of value in experimental and model designing work. This is the second enlargement of Mr. Baillard's facilities during the last few years, the growth of his business being the natural outcome of the remarkable value of his services to inventors, machine designers and patentees, due to his wide experience in machine designing and unusual ability in assisting patrons in the solution of the many electrical and mechanical problems that arise in their work.

MURPHY AUTOMATIC SMOKELESS FURNACES were placed under the boilers of the Central High School building, Detroit, Michigan, about two years ago, displacing ordinary hand-fired furnaces. The economy realized has been so marked and the service so satisfactory in general that the Board of Education has closed a contract with Murphy Iron Works, Detroit, Michigan, to equip the boilers of all the school buildings of the city. Other recent sales are two additional furnaces for the Youngstown (Ohio) Electric Light Company, the Buffalo Cold Storage Company's plant, Buffalo, N. Y., the Home Telephone Building, and the Rose Building, Cleveland, Ohio., and the Union Iron & Steel Company's plant, Youngstown, Ohio. Four additional have been ordered by the United Traction Company, Pittsburgh, Pa., and two additional by the Western Reserve Building, Cleveland, Ohio, as well as two by Stanley R. McCormick's Building, Chicago.

MESSRS. MORRIS E. LEEDS & CO. have purchased the plant, drawings, fixtures, etc., of Elmer G. Willyoung & Co., and will continue the business at the old address, 939 Boyer St., Phila. Mr. Leeds is personally well equipped to conduct the business of manunfacturing scientific apparatus, as he has engaged in this line for the last ten years. His experience in this line has been general while filling the position of manager of the electrical and physical department of Queen & Co., Inc., which he resigned in May of the present year to engage in the enterprise already mentioned. The knowledge gained in his extended acquaintance with foreign manufacturers and methods, supplemented by five years of careful study of the requirements of the scientific public of America, has been of great value, and will be put to good use in developing the business of Morris E. Leeds & Co. Mr. James G. Biddle, 1038 Drexel Building, Phila., who acted as sole agent for Willyoung & Co., will act in the same capacity for Leeds & Co., so that as regards the selling end of the business there is no change whatever.

THE HARRISON SAFETY BOILER Works announces a large list of recent sales of Cochrane Heaters and Cochrane Separators, among which are the following to electric light, street railway and electrical manufacturing companies: Cochrane heaters—Edison Electric Illuminating Company, Boston, Mass., 4000 h.p.; Worcester Electric Light Company, Worcester, Mass., 1500 h.p.; Saratoga (N. Y.) Traction Company, 150 h.p.; Rockland, Thomaston & Camden Street Railway Company, Rockland, Mo., 250 h.p.; Commonwealth Electric Company, Chicago, Ill., 3000 h.p.; Fort Worth (Tex.) Light & Power Company, 850 h.p.; Spartansburg (S. C.) Electric Light & Power Company, 600 h.p.; Cochrane separators—Missouri Railroad Company, St. Louis, Mo., 36-in. vacuum oil and two 12-in.; Saratoga (N. Y.) Traction Company, 10-in.; Missouri Edison Electric Company, St. Louis, Mo., three 10-in. receiver and one 10-in. horizontal; Spartansburg (S. C.) Electric Light & Power Company, three 6-in.; British Columbia Electric Railway Company, Ltd., Vancouver, B. C., two 8-in.; Electric Storage Battery Company, Philadelphia, Pa., 8-in.

MR. ELMER G. WILLYOUNG announces that he has discontinued the instrument business lately carried on by him in Philadelphia, Pa., under the designation of Elmer G. Willyoung & Co., and sold the plant in lump. He has made a close alliance with Messrs. Foote, Pierson & Co., of New York City, for a term of years. By the terms of this compact they will make, under his personal supervision, a full line of high class scientific and technical instruments and apparatus. To this end they have just added additional floor space, amounting to about 5000 square feet, to their already extensive plant, at 82-84 Fulton Street, which space is being equipped with the most modern and improved tools and appliances. Messrs. Foote, Pierson & Co, are the successors of the manufacturing department of E. S. Greeley & Co and are hence known to the electrical fraternity as makers of telegraph instruments and special mechanical devices. The contract constituting Mr. Jas. G. Biddle of Philadeplia, Pa., sole selling agent of Willyoung apparatus has been annulled, and henceforth Willyoung apparatus can be obtained only from Messrs. Foote, Pierson & Co. or the trade generally.

THE WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY has recently equipped with electrical apparatus the building of the University Club, 5th Avenue and 53d Street, New York. The specifications were drawn up by Mr. C. O. Mailloux. The equipment includes one 75 kw., one 50 kw. and one 25 kw., 125 volt "engine type" Westinghouse generators, each direct connected to its own engine. The club will be handsomely illuminated with clusters of electric lamps. Another interesting installment recently completed by the same company is at Baron de Hersch's trade school on 64th Street, between 2d and 3d Avenues, New York City. The equipment includes one 50 kw. and one 25 kw. Westinghouse generator, 125 volts. The entire outfit at the trade school is a typical one, great care having been taken in arranging every part, as the school classes are taught the working of electrical apparatus by studying the operation of the machinery on their own premises. The Westinghouse Company has also contracted with the Burns estate to supply an electrical outfit for the new hotel now building at 5th Avenue and 45th Street, New York City. The installation will comprise one 150 kw. and one 100 kw., 230 volts, Westinghouse multipolar generators, direct connected to steam engines, running at 250 r. p. m.

THE PITTSBURGH BOILER SCALE COMPANY, Pittsburgh, Pa., offers a solution of the boiler scale problem quite different from most others in commercial use. Instead of treating the water by means of chemicals, which are likely to prove injurious to engine valves and packings, and instead of allowing the scale to form and afterwards removing it mechanically, the vaporizing surfaces of the boiler may be coated with a thin film of Pittsburgh boiler scale resolvent, which film will have the peculiar property of preventing the scale from attaching itself to the iron. The introduction of a little of the resolvent with the feed water will serve to coat with a greasy film each individual particle of the material as it solidifies, which will prevent these particles from forming into a hard, scaly mass and help hold them in suspension in the water, so that they may be readily removed by blowing down or washing out the boiler. The compound is a petroleum product, freed from any tarry ingredients that would injure boiler or engine surfaces and having a vaporizing point far above the temperature of the boiler, which insures it from passing off with the steam. It can be applied by means of a brush or swab to the shell, flues or tubes of the boiler when the latter is cold and dry, but may also be introduced into boilers with considerable scale on the surfaces. Its effect in the latter case is to gradually disintegrate the scale already formed, and in time reach the surface of the iron and form a film thereon.

THE UNION BOILER TUBE CLEANER COMPANY, of Pittsburgh, Pa., was organized in 1895 for the purpose of introducing an

entirely new industry, that of removing scale from the interiors of the tubes of water tube boilers. It has machinery especially designed for this specific business, by which it is enabled to safely contract for thoroughly cleaning boilers under a time limit with bond for heavy penalty for non-fulfilment, or to sell or lease tools for cleaning all makes of water tube boilers having straight, horizontal, inclined or vertical tubes, as well as those having curved tubes such as the Climax, Stirling, or even the Hazleton, having closed end tubes. The latter three types have heretofore been considered, and without this company's devices are yet, impossible to clean. The company commenced business as a firm May 1st, 1895, a time of the greatest industrial depression in the history of the country, notwithstanding which the great merits of the devices caused their immediate adoption by the largest concerns in the United States and England. Their value as a fuel saving device, as well as one that increases the efficiency of boilers even when practically new, was such as to call forth the highest praise from users. Such is the continued demand that notwithstanding the company started with a well equipped factory it is constantly enlarging the works, putting in additional machinery, and has more than doubled the force of workmen since the first of the year in its endeavors to keep up with orders. It has a flexible shaft which is unique in its way; having been compelled to design one to clean boilers having curved or other tubes inaccessible for a stiff rod, owing to the fact that other shafts would not stand the wear and tear under great stress.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., have experienced during the last few years a phenomenal growth which shows the enormous demand for the kind of work they do as well as the satisfactory way in which they are doing it. The work of the schools has reached a magnitude which few unacquainted with them would ever imagine. The entire staff connected with the instruction and business department of the school numbers about 1,000 employees, of which 120 constitute the corps of instructors and assistants in the 57 distinct courses of study given. The number of students enrolled reaches the enormous aggregate of some 90,000. The equipment of the schools for handling this work is necessarily quite elaborate. The headquarters of the schools are located in two large buildings recently erected at a cost of $250,000. One of these, five stories in height is occupied by the business offices and instruction departments, and the other, a four-story building, is devoted exclusively to the printing and book-making departments. The amount of work carried on by correspondence is indicated by the fact that the postage expenses of the schools average in the neighborhood of $125 per day. In addition to the home office are more than a dozen branches maintained in the principal cities throughout the country, each under the charge of a superintendent. The territory of each of these branches is further divided into districts, each being in charge of an assistant superintendent. The business dealings of the school with its students are carried on by a number of solicitor collectors, under the charge of these assistant superintendents. The instruction and preparation of text books is carried on at the home office with the exception of a recent departure in the railway courses for which a car has been built which travels about the country giving students an opportunity to obtain a personal explanation of difficult points. This car has proven so satisfactory that two others are being built for the same purpose. The schools are controlled by the Colliery Engineer Company, incorporated with a capital of $1,250,000. The founder and General Manager is Mr. T. J. Foster, who established the schools in 1891.

## HAUNTS IN THE WILD WOODS
AND
## GAY PLACES FOR SUMMER OUTINGS.

Either or both, can be found along the lines of the Chicago, Milwaukee & St. Paul R'y in Wisconsin, Minnesota, Northern Michigan, Iowa and the Dakotas. Among the many delightful summer resorts are Delavan, Waukesha, Oconomowoc, Elkhart Lake, Marquette, Madison, Kilbourn, Minocqua, Star Lake, Lakes Okoboji, Spirit Lake, Clear Lake, Big Stone, Frontenac, White Bear and Lake Minnetonka. In the north woods of Wisconsin, in the forests of Northern Michigan and Minnesota, and in the far stretches of the Dakotas true sportsmen can fish and hunt to their heart's content. Vol. XI. New York, September, 1899. No. 9.

## THE AUBURN STATION OF THE CENTRAL CALIFORNIA ELECTRIC COMPANY.

**An Auxiliary Hydraulic Station Running in Parallel With Another Five Miles Away.**

The Central California Electric Company has recently erected an electric power house at Auburn, Placer County, California, to supplement the power already developed at New Castle and transmitted to Sacramento. The South Yuba Water Company provides irrigation for a vast tract of rich country on the Sierra Nevada Divide, northeast of Sacramento. At points upon the main canal, the water passes through rapids and over falls. One of such changes in level has been utilized by the Central California Electric Company, who two years ago erected a plant at New Castle to generate electricity. A reservoir was constructed and the water piped a distance of 6400 feet to the power house, where it is used to drive Pelton water wheels, which are direct connected to the 400-kw. Westinghouse two-phase generators. The power is generated at 500 volts two-phase, and passed through four 150 k.w. step-up transformers, which change it to three-phase at 15,000 volts, in which form it is transmitted to Sacramento, a distance of 29 miles.

The successful operation of this long distance transmission plant has led to the recent addition at Auburn, five miles beyond New Castle. About one mile north of the city of Auburn, the main, or Bear River, canal of the Yuba Water Company has a fall of about 200 feet within a distance of half a mile. Previous to the summer of 1898 the water flowed down Auburn Ravine, but has since been diverted to the canal. At this point of junction the new power house has been erected. A reservoir, capable of holding a day's supply, was built at the head of the ravine. The pipe connecting the reservoir and the power house is of riveted sheet steel varying in thickness from No. 12 to No. 6 at the receiver end. It is altogether 3100 ft. in length, the first 20 ft. being 54 ins. in diameter, which narrows to 200 ft. of 40-in. and finally to 36-in., which size is

VIEWS AT THE AUBURN POWER HOUSE OF THE CENTRAL CALIFORNIA ELECTRIC COMPANY.

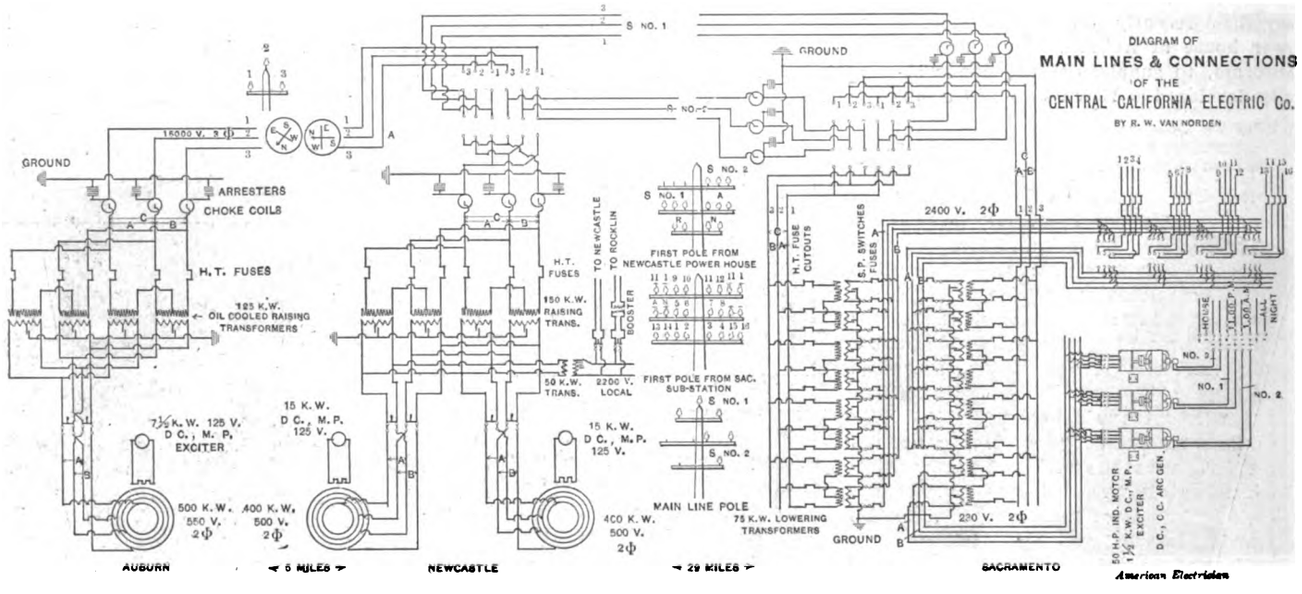
Digitized by Google

maintained throughout the remainder of its length. With the exception of about 200 ft. the pipe is buried at least one foot under the surface.

The power house is a frame structure 30 by 40 ft., covered with corrugated iron, the interior having a wainscoting of redwood up to the eaves. A composite traveling crane of ten tons capacity runs the length of the building. The main generating set is at the lower end, and is on a solid rock foundation. The water wheels being of small diameter, owing to the low load, the floor around their framework is higher than the generator floor, by this means the least possible head is lost in the discharge. The water wheels consist of two double nozzle solid disc 43-in. Pelton impulse wheels enclosed in a cast iron and sheet steel case. Working over the nozzles are deflecting hoods manipulated by a hand wheel in front of the switchboard. The wheel shaft is connected to that of the generator by a fly wheel link leather coupling. The fly wheel is six feet in diameter, and weighs 6000 lbs. The coupling is made by twelve links 6 ins. wide.

The entire electrical equipment was furnished by the Westinghouse Electric & Manufacturing Company. The generator is of the revolving armature type, rated at 500 kw. capacity, 550 volts and 60 cycles at 300 r. p. m. The generator is set on four blocks of granite which stand on the natural bed rock, and are well grouted with cement. The cables from the generator run under the main floor to the switchboard and thence to the transformers which are behind it. On a shelf against the rear wall and over the transformers are the lightning arresters. There is but one panel in the switchboard which, however, contains all necessary instruments.

The transformers, four in number, are of 125 kw. capacity each, and transform from 550 volts two-phase to 15,000 three-phase. High tension fuses are in a framework under the arresters. At one side of the building near the main water wheel, but on the station floor proper, is a 7½ kw. exciter, direct connected to a 12 h. p. Pelton water motor, mounted upon the same base.



The regulation is done entirely by using the deflecting hoods before mentioned, which throw the water directly into the tail race. There is no attempt at saving water at low loads, as the flow in the canal must be maintained at all times. A bypass is provided to keep up the supply of water in the canal when the machines are not running. The main pipe is tapped near the rear of the building with an 8-in. gate valve, with a discharge pipe into the tail race; this, as well as the main pipe in the building, is imbedded in concrete to prevent any vibration or displacement. At the rear of the building a 12-in. gate valve in the main pipe discharges into the ravine. The exciter, main gates, regulator and switch board stand in the power house within a radius of six feet, thus facilitating hand regulation of all to the greatest degree.

The main transmission line consists of three No. 4 hard drawn copper wires supported on Locke triple petticoat glass insulators on locust pins, the latter being boiled in paraffin before using. The poles are of sawed redwood, 30 ft. high. The line runs directly to the New Castle generating station, terminating in a marble "plug board." This board has two panels and four sets of three plugs each. The New Castle and Auburn plants are arranged to run in parallel, the current being transmitted to the city of Sacramento, which is twenty-nine miles distant from New Castle and thirty-four miles from Auburn. The synchronising lamps at Auburn are connected in, one on the transformer and one on the generator side of one of the main switches. In order to synchronise the two plants, current from the plant which is running is allowed to flow to the other station, stepping down through the transformers. The generator is then started, and the switches thrown in in the ordinary manner. There has been no trouble experienced; in fact, if the machines are not exactly in synchronism when the switches are thrown, they will pull together with apparent small effort. When the two stations are running together all regulation is done at New Castle, the station at Auburn carrying a fixed load, dependent on the position of the hoods in its wheel. This load is increased or decreased in 100 h. p. changes, as the total load may require, and at the direction of the man in charge of the New Castle station.

The diagram printed below gives the general lay out of the circuits from Auburn through New Castle to Sacramento with the arrangement of the wires upon the poles of the various lines. Among other things may be noted the ingenious arrangement of the "plug board" at New Castle, referred to above, which is shown in the upper part of the New Castle section of the diagram. By means of twelve plugs either the Auburn or the New Castle plants may be run on either of the transmission lines or both in parallel.

A similar plug arrangement is shown at Sacramento for operating either transmission line or both in parallel independently, on either bank of step-down transformers, or both in parallel. The location of fuses, lightning arresters, etc., if studied, will show an admirable fitness to the purpose of giving maximum protection with a minimum amount of apparatus.

We are indebted to Mr. Rudolph W. Van Norden for the particulars of the building and construction.

THE CIRCUITS OF THE TWO POWER HOUSES AND THE SUBSTATION OF THE CENTRAL CALIFORNIA ELECTRIC COMPANY.

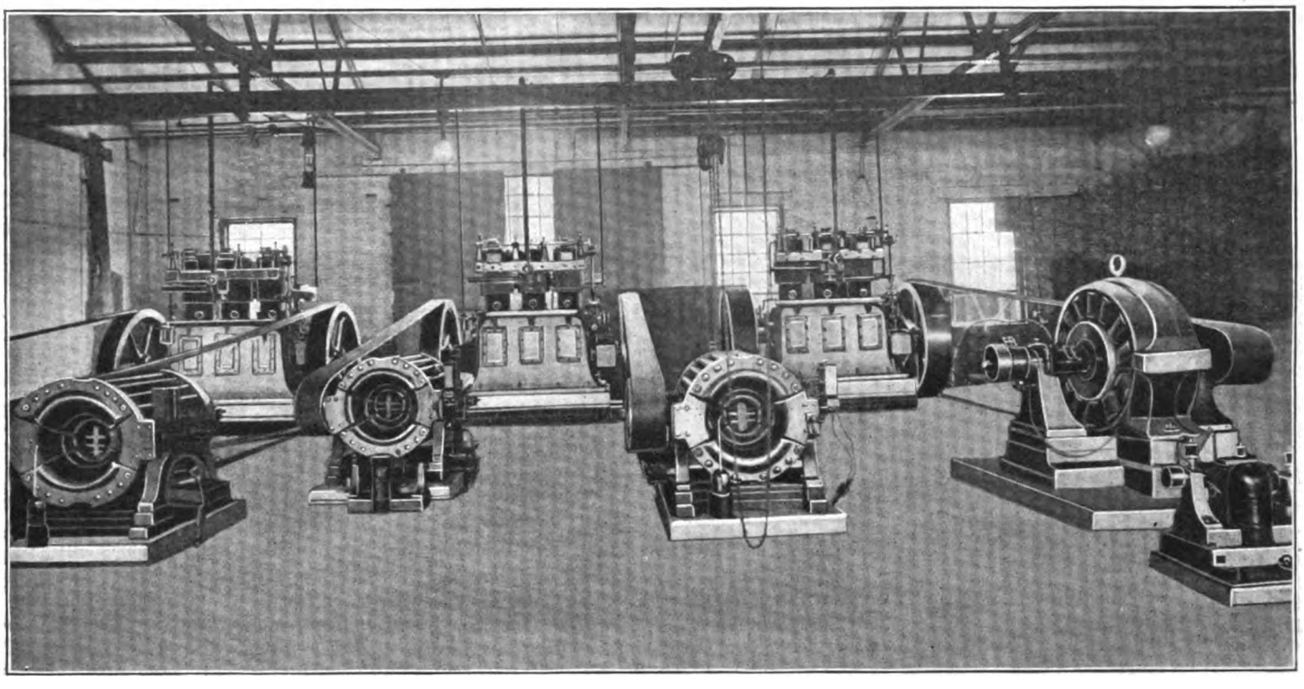
## A GAS ENGINE CENTRAL STATION AT BRADFORD, PA.

The Bradford Electric Light & Power Company, Bradford, Pa., has the largest equipment of gas engines for electric lighting purposes completed as yet in this country. The company contracted some months ago with Messrs. Westinghouse, Church, Kerr & Company for three gas engines of 125 h. p. each, and one of 200 h. p., to be built by the Westinghouse Machine Company, East Pittsburg.

The new gas engine equipment constructed under this order replaces four automatic high speed steam engines of the same aggregate power, two of which were belted to a jack shaft from which the dynamos were driven, the other two being belted direct to dynamos in a wing off the main engine and dyanmo room. Steam for the engines was supplied by four 100 h. p. horizontal return tubular boilers, fired by natural gas. The amount of gas consumed for these engines amounted to fifty-two cubic feet per indicated horse-power per hour.

A new and more convenient arrangement of the floor space in the engine room has been made by placing the four gas engines on one side of the main room and belting them direct to the dynamos. Two of the 125 h. p. gas engines drive the four arc dynamos, two on each engine. One of the alternators is so placed that if necessary it can be driven by one of these engines. The third 125 h. p. engine drives the second alternator, and the 200 h. p. gas engine drives a 125 kw. Westinghouse alternator.



The Bradford plant is unique in that it is the first extensive electrical system in which steam power has been entirely displaced by gas engines. The fuel used is natural gas, of which the consumption is guaranteed by the Westinghouse Machine Company not to exceed thirteen cubic feet per brake horse-power hour. The saving in fuel alone, as compared with the former consumption of fifty-two cubic feet, will be a large item, and pay a handsome percentage upon the investment.

The floor space saved by the present arrangement of engines and dynamos, and the boiler space soon to be vacant, will be of value when additions have to be made to the present plant. The saving in boiler repairs, brick work and labor in boiler room is another considerable item. Better supervision is secured, as all the work is now concentrated in the one room.

A Clayton air compressor, driven by a small gas engine, is used to charge two air reservoirs placed overhead in the engine room. The compressed air is used to start the large gas engines. The small gas engine also operates a triplex pump which furnishes water to the jackets of the gas engines for cooling purposes. The small gas engine is equipped with a governor arranged for three speeds to accommodate the change of loads on the engines.

The view given above shows the plant before the reconstruction was completed, only three of the engines being in place.

At the present time it is too early to state what the average consumption of natural gas will be, but from records already taken the cost of fuel for one engine working 102 arc lights is about $1.12 for eight hours' service. The future working and development of this plant will be a valuable guide to users of power, and will be watched with keen interest.

THE CENTRAL STATION OF THE BRADFORD ELECTRIC LIGHT AND POWER COMPANY, SHOWING GAS ENGINES DRIVING ALL GENERATORS.

## PLEA FOR A WORKING STANDARD OF LIGHT.*

There are scattered over the country many well equipped photometric laboratories, and in the near future every central station and large isolated plant will be provided with means for measuring light. There is not now in existence any workable primary standard which can be used by the ordinary photometer corps.

A lamp user may say to the manufacturer, "Your standard is wrong," and neither ever dreams of suggesting a recalibration; they know by experience that an agreement can not be reached. No observer can even duplicate his own work. What is the result? Every lamp maker in the country is sending out some lamps which are wrongly marked according to his own standard, because some of his customers have standards of their own.

Lamp makers differ among themselves, and there exists no way by which they can be brought together. It is obviously to the interest of the whole electrical engineering fraternity that some action looking to the correction of this condition be inaugurated.

I wish to go on record as saying that in a very few years the incandescent lamp will be adopted as a primary standard. It could be so adopted to-day if lamp makers would only tell what they know.

A committee should be formed which would send out, under proper restrictions, proper seasoned and calibrated incandescent lamps for use as secondary standards. Such lamps, if carefully burned, would maintain their candle power constant and do away with the greater part of existing variations.

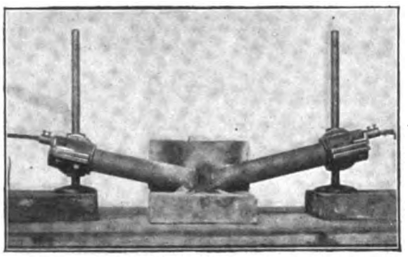
## The Experimental Electric Furnace.

BY SAMUEL AUCHMUTY TUCKER, PH. B., F.C.S., OF THE CHEMICAL DEPARTMENT, COLUMBIA UNIVERSITY.

From the very earliest times it was found necessary to heat substances in order to bring about chemical change, and we know that every alchemist had his forge, which was used in the vain endeavor to transmute the baser metals into gold. This primitive method of heating has been changed with the introduction of gas, which is the usual accompaniment to every chemical laboratory, and indeed the modern gas furnace leaves little to be desired for all ordinary operations, but when higher temperatures are required, special means must be adopted. The discovery of the oxyhydrogen blow pipe gave us a very powerful source of heat, and many refractory substances were found to yield to its influence, for a temperature of 2000° C. is easily reached. A mass of platinum weighing 200 pounds has been melted at one operation by this apparatus. The calcium light is a familiar example of the use of this source of heat, the lime pencil being raised to a high

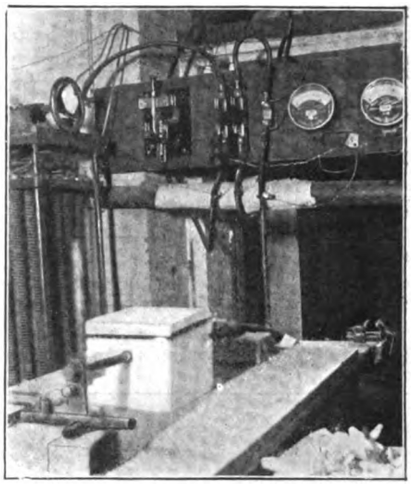


MOISSAN'S FURNACES, ARRANGED TO SHOW THE SUBLIMATION OF SILICA.

state of incandescence when the flame impinges upon it.

The electric arc, however, far exceeds other means for the production of high temperatures, and the ease with which it can be handled, enabling one to produce the heat instantly, makes it a most valuable addition to scientific research.

Every one is now familiar with the electric arc, but few realize what a very intense heat is produced; the carbon particles which form the arc are raised to such a temperature that practically nothing can withstand its effect. The temperature is probably the same in all cases where an arc is produced, that is the volatilizing point of carbon, but this temperature is by no means easy to estimate, for no thermometer or pyrometer can be used; and Violle, who has given us the most information on the subject, was obliged to resort to calorometric methods. His apparatus consisted of a powerful arc produced by a current of 450 amperes at 85 volts between two carbon rods one of which was formed into a button at the end, which could be easily detached; directly underneath this was placed a small copper vessel surounded with a given weight of water at a known temperature with appropriate heat insulation. After the carbon button had become thoroughly heated it was broken off and allowed to fall into the copper vessel. The rise in temperature of the water enabled Violle to calculate that for 1 gramme of carbon at the temperature of the arc to carbon at 0°C, 1600 calories are yielded up. Weber



HORIZONTAL TYPE OF ELECTRIC FURNACE.

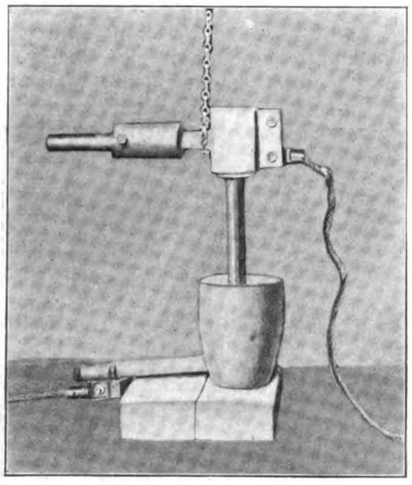
had already proved that 300 calories were necessary to heat 1 gramme of graphite from 0° to 1000°C, consequently there remains 1300 calories from 1000° to the volatilizing point of carbon; and knowing the specific heat of carbon to be 0.52, these 1300 calories represent a temperature of 2500°C, which added to the 1000°, equals 3500°C, which is at least the approximate temperature of the electric arc. It is readily seen that the method is open to several difficulties, for not only is there loss of heat by the fragment of carbon in falling into the calorimeter, but the specific heat of carbon probably varies at different temperatures. However, if we do not know the exact temperature we do know the effects which this form of heating is capable of producing, and they are indeed very remarkable. The use of the electric furnace has become very important in the last few years, for compounds are formed at the high temperature obtained which before were unheard of, and several industries have been established which have been the direct outcome of experimental research in the laboratory.

Henri Moissan stands at the head of this branch of the subject and his furnace is extremely well adapted to work of this kind; it consists of two blocks of chalk, one of which is hollowed out to hold a small carbon crucible, the carbon electrodes passing through two grooves horizontally; the other block of chalk acts as a cover and is cut so as to fit perfectly over the base.

The chalk on heating gives up its carbonic acid, becoming quicklime, which is

ARRANGEMENT OF APPARATUS FOR EXPERIMENTAL ELECTRIC FURNACES.

exceedingly resistant to high temperatures, but even this substance will melt at the temperature of the arc, and we have obtained beautiful crystalline pieces of lime while working with this furnace. At times, especially for continuous use, it is advisable to use layers of carbon in the form of plates separated from the lime by some magnesia, as magnesia forms no carbide.



With this furnace Moissan investigated the many refractory substances with which we are familiar besides the production of carbides and rare metals, and carried on a very brilliant research into the nature of the different varieties of carbon, which led to the production of the artificial diamond. One great advantage which his furnace possesses, is that there is no electrolytic action, the substance to be treated being simply exposed to the radiant heat. A beautiful experiment, and one that well shows the high temperature reached, is the volatilization of quartz which may easily be made with the Moissan furnace. We have used powdered rock crystal which has been previously dried in an oven, a small quantity being placed in the crucible, a hole is bored in the cover to allow the escape of the gases and the current turned on. The best effects are obtained with a current of 300 amperes and 80 volts. The quartz melts instantly and is changed into gaseous silica, which passes through the hole in the cover and may be collected as a fine white powder on a glass cylinder placed above.

The illustration shows the arrangement of the apparatus, and we may judge of the degree of heat obtained when we consider that the parts of the metallurgical furnaces used in the manufacture of steel, are made purposely of silica bricks to withstand the highest temperatures in such operations.

Digitized by Google

We have made the same experiment with a 20-ampere arc, using a small furnace and an ordinary lamp chimney to collect the silica upon, but generally a current of high power is required for this kind of work. In our own laboratory we have a direct current of 300 amperes at 110 volts, and the arrangement is here shown of the rheostats, switches, etc., which are used in controlling and reading the current.

The manufacture of calcium carbide, as well as the carbides of other metals, on a

VERTICAL TYPE OF ELECTRIC FURNACE.

small scale, is not difficult, provided we have a current of suitable power. These substances are particularly interesting and commercially important in the case of the carbides of calcium and that of silicon. Many of them decompose water with the evolution of acetylene gas, according to the reaction:

$$CaC_2 + H_2O = C_2H_2 + Ca(OH)_2.$$

And it was due to this very reaction that Willson, in 1888, noticed the formation of calcium carbide while making some experiments upon the production of metals by heating their oxides with carbon in an electric furnace. The substance itself had, however, been discovered by Wöhler in 1862, who obtained it in a totally different way. The table gives a list of the various carbides, with other information which may be useful.

| | Name. | Formula. | Discoverer. | Remarks. |
|---|---|---|---|---|
| Decomposed by water. | Aluminum | $Al_4C_3$ | Moissan, 1894. | Water evolves methane. |
| | Barium | $BaC_2$ | " 1894. | " " acetylene. |
| | Calcium | $CaC_2$ | Wöhler, 1862 | " " " |
| | Cerium | $Ce_2C$ | Moissan, 1896. | " " " ethylene and methane. |
| | Glucinum. | $Gl_4C_3$ | Lebeau, 1895. | " " methane. |
| | Lanthanum. | $LaC_2$ | Moissan, 1896. | " " acetylene, ethylene and methane. |
| | Lithium | $Li_2C_2$ | " 1896. | " " acetylene. |
| | Manganese | $Mn_3C$ | Troost and Hau'efeiulle | " " methane and hydrogen. |
| | Potassium | $K_2C_2$ | Davy, 1808. | " " acetylene. |
| | Sodium | $Na_2C_2$ | Berthelot, 1863. | " " " |
| | Strontium. | $SrC_2$ | Moissan, 1894. | " " " |
| | Thorium. | $ThC_2$ | Moissan, Etard. 1896. | " " acetylene, hydrogen, and hydrocarbons. |
| | Uranium. | $Ur_2C_3$ | Moissan, 1896. | Water evolves acetylene, methane, hydrogen, and solid and liquid hydrocarbons. |
| | Yetrium | $YC_2$ | Petterson, 1895. | Water evolves hydrogen. |
| | Zirconium. | $Z_2C$ | Moissan, 1896. | " " methane, acetylene and ethylene. |
| Not decomposed by water. | Boron. | $B_4C$ | " 1894. | Harder than corundum. |
| | Chromium. | $Cr_3C_2$ | " 1894. | " " topaz. |
| | Molybdenun | $Mo_2C$ | " 1893. | |
| | Silicon. | SiC | Acheson, Moissan, 1893. | " " corundum. |
| | Titanium. | TiC | Moissan, 1895. | Takes fire at red heat. |
| | Tungsten. | $W_2C$ | " 1893. | Harder than corundum. |
| | Vanadium. | VaC | " 1893. | " " quartz. |

Carborundum, or silicon carbide, is not decomposed by water, but its great hardness makes it valuable as an abrasive substance. For the preparation of calcium carbide we make use of the vertical style of furnace, which is really of the Willson type. The figure shows this furnace, and it simply consists of a plumbago crucible having one of the carbon electrodes passing through a hole bored in the side, the other being suspended vertically with some means whereby it may be easily raised and lowered. Suspension of this electrode by a chain and counterpoised weight is the best arrangement, for it admits of the arc being passed easily over the surface of the charge just as we might pass the flame of a blow pipe over anything which we wished to heat.

The charge is made up of 56 parts of quicklime and 36 parts of coke, both being finely powdered and evenly mixed. The vertical carbon is lowered until it forms an arc with the one through the side of the crucible and the material is gradually added. Good results are obtained by using a current of 150 amperes at 50 to 60 volts, and it takes but a few minutes to form a carbide ingot of fine crystalline structure. The operations may be watched through thick smoked glasses, but the greatest caution should be exercised while working with an electric furnace, for not only the eyes are in danger, but severe sunburn as well as sunstroke are not at all uncommon. For the preparation of chemically pure carbides it will be found advantageous to line the plumbago crucible with carbon, in order to prevent the introduction of any impurities from the clay which is always used in its manufacture. Aluminum bronze as well as ferro aluminum may be prepared in this furnace, or the electrodes may be arranged at an angle as shown in the illustration, the charge of alumina, coke, and copper or iron, as the case may be, being surrounded by fire clay bricks. This is really the manner in which these bronzes were first manufactured by the Cowles process, but at the present time it seems easier to make them by melting together pure aluminum with the necessary metal.

## THE CONSTRUCTION OF A CRADLE DYNAMOMETER.

BY PROF. A. F. M'KISSICK.

The cradle dynamometer, shown in Fig. 1, was built for the purpose of measuring the power delivered by a five-horse-power induction motor (mounted on dynamometer) to a belted dynamo, and, while the cost of construction has been small (not exceeding six dollars), it has been found

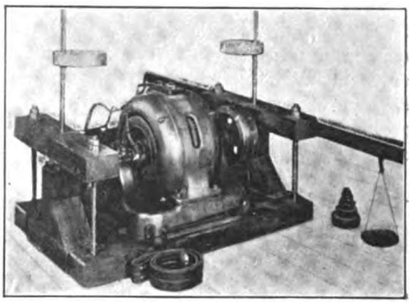


FIG. 1.—CRADLE DYNAMOMETER.

to measure the transmitted power quite accurately, and has proven very satisfactory.

The dynamometer was constructed chiefly of yellow pine (6 in.x4 in.), the knife-edge and support upon which the knife-edge rests being hardened steel, the vertical rods ¾-in. steel and the elliptical counter-weights cast-iron. On account of the belt being horizontal, some difficulty with a side pull was feared, but acting according to a suggestion of Prof. W. E. Goldsborough, in making the knife-edge and support, as shown in Fig. 2, no bad effects were experienced.

It is very important that the two knife-edges should be in line with the axis of

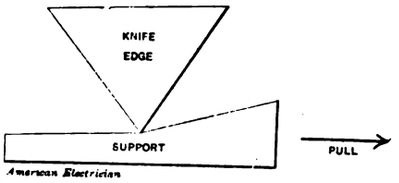

FIG. 2.—ARRANGEMENT TO RESIST BELT PULL.

the machine. An excellent device for setting the axis of the machine in line with the knife-edge is given in Flather's "Dynamometers and the Measurement of Power," on page 103, which is as follows:

"The device consists of two equal weights hanging from each end of a piece of belt, which is hung over the pulley of the machine. The weights together should, preferably, be about equal to the pull of the belt. The machine is adjusted so that hanging these weights on causes no change in the position of the scale beam, and any irregularity in the pulley is eliminated by trying it with the pulley in positions 180° apart."

By means of the cast-iron counter-weights the machine can be balanced, and also the center of gravity of the system be made to nearly coincide with the axis of the machine, being slightly below it.

## THE INDEPENDENT TELEPHONE EXCHANGE OF THE LAFAYETTE TELEPHONE COMPANY.

It was in February, 1896, that the Lafayette Harrison Telephone Company began to serve patrons in Lafayette, Indiana, and at that time its exchange was equipped throughout with the Harrison International apparatus, including the Harrison switchboard. This entering of the field by a new company forced the Bell Telephone management to seek improvements, and they, in turn, refitted their local exchange with all that their skill and experience could discover to improve the service. It was hoped by them that the Harrison Company would prove but short lived, but in this they were disappointed, largely on account of the public feeling in favor of an independent company.

The exchange was then built to accommodate 350 subscribers, that being about 150 more than the city had ever before furnished. In a very few months it was found necessary to add another section of switchboard, and in an additional brief time another was required, and so on until accommodations for 800 were provided. Always on the lookout for anything that would better serve its patrons, the company installed the Beech-Cook transfer system on the old Harrison board, and a decided improvement in the exchange was at once noted.

But still the patronage of the company increased, and further improvements were imperative. The Lafayette Telephone Company, as it had come to be called, then fitted its exchange with the complete equipment of the Sterling Electric Company of Chicago, this equipment consisting of eleven 100-drop sections of switchboard, a distributing board for 1200 pairs of wires, chief operator and monitor's desk, and 11 combined cable terminals and protectors. Fig. 1 gives an idea of the appearance of the board, the distributing board being to the right of the switchboard. To the rear of the switchboard and distributing board can be seen the tops of the combined cable terminals and protectors, as they are located back of the board.

The chief operator and monitor's desk is situated in the middle of the floor and immediately in front of the switchboard. By means of this board the chief operator has constant supervision over the entire working force of the exchange.

The switchboard proper consists of 11 sections of Sterling metallic board of 100 drops each. The drops (see Fig. 2) are a bipolar tubular type, the armature being located midway of the spool concentrating both poles of the magnet at that point, thus deriving all magnetic force possible from the ampere turns, making a very sensitive drop. The core shield and armature are made of imported Norway iron stock. The winding is of single silk magnet wire, each spool having a resistance of 500 ohms. The drops are assembled on metal plates, five to a plate, twenty plates being mounted within each 100-drop cabinet. Each drop shutter is equipped with a restoring slide and under each bank of ten drops there is placed a restoring lever which operates the slide upon each and every drop in the bank of ten.

The jacks are mounted upon a fibre-faced hard wood jackboard, placed immediately under the drop panels. The jacks are of the bridging type and each jack is made of a body casting upon which are mounted three German silver springs, insulated with hard rubber bushings. The jack is held to place in the jackboard by means of a lock nut, placing the jack in from the rear of the board, and the lock nut from the face, this lock nut acting as the barrel to the jack and also the face upon the board. This arrangement is illustrated in Fig. 3. Each jackboard is equipped with 100 jacks, numbered to correspond with the drops directly above them. Immediately under the regular jackboard are placed the transfer jacks, which are used to transfer

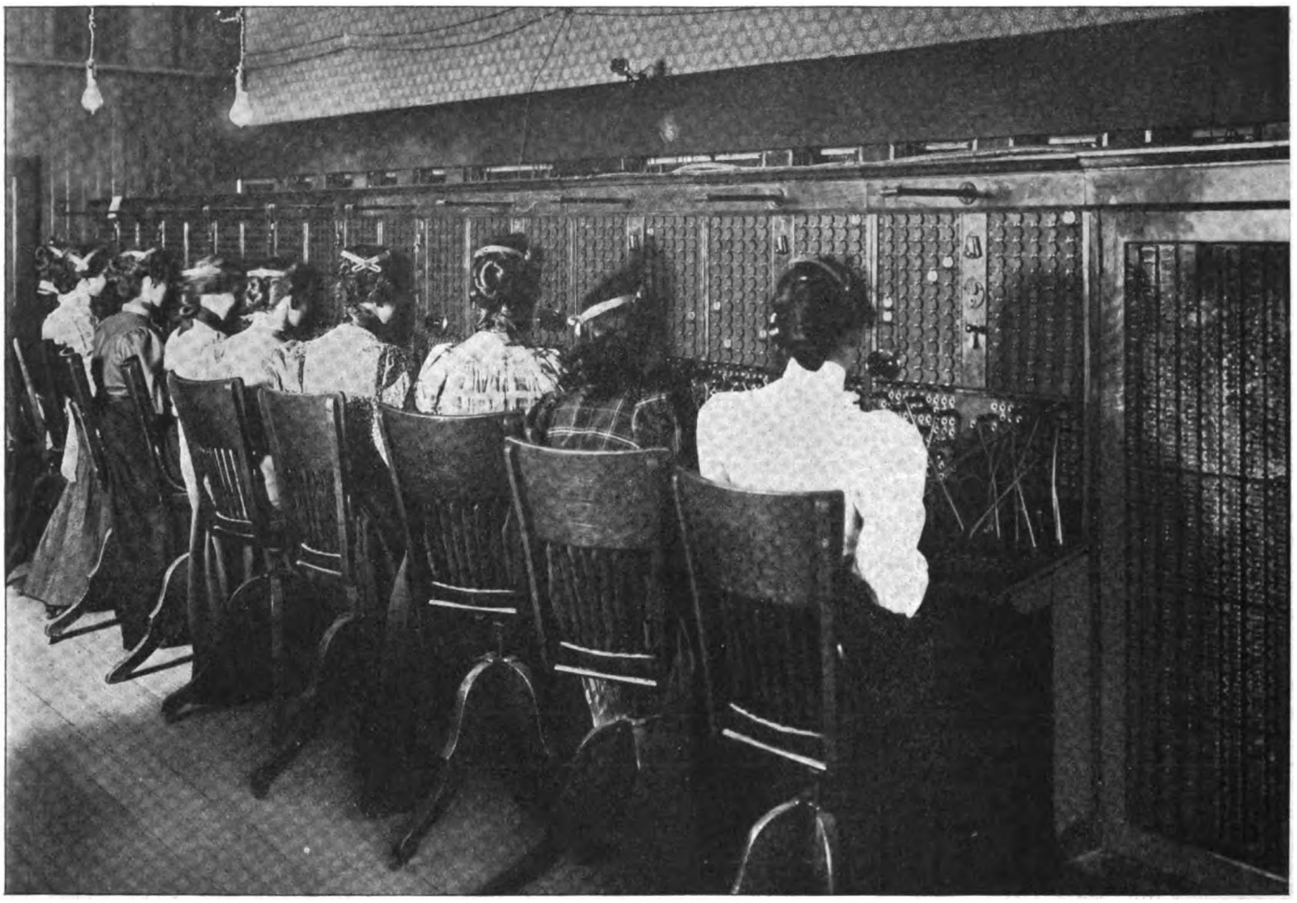

FIG. 1.—THE SWITCHBOARD OF THE LAFAYETTE EXCHANGE.

Digitized by Google

connections to distant boards. These jacks (see Fig. 4) are of brass body casting, mounted in the same manner as the bridging jack, the structural details being different, however.

The keyboard, which is made of three-ply oak, placed upon an incline, is mounted with 10 pairs of metallic cords and plugs, 10 ringing and listening keys, and 22 transfer cords and plugs. The

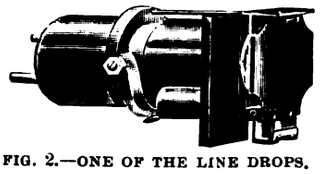

FIG. 2.—ONE OF THE LINE DROPS.

regular cords and plugs are for answering the calls upon that section of board, while the transfer cords and plugs are for putting up connections when called for from distant boards. Immediately in front of each transfer cord there is an order key for testing in upon a transfer cord. Each pair of cords is equipped with one long and one short plug, and the ringing and listening key consists of a cam lever and two push buttons, one push button ringing upon the inner cord and one upon the outer cord, there being but two positions of the cam lever, forward and back, which cuts in and out the operator's telephone set from the cord circuit.

Upon the falling of a drop the operator pulls the cam lever upon the ringing and listening key toward her, taking the short back plug, inserting it within the jack corresponding with the drop, restoring the shutter at the same time, putting up the connection with the front or long plug and ringing by means of pressing upon push button corresponding with that cord and plug, afterwards restoring the cam lever to place, thus cutting out the telephone set. When the parties talking ring off it is recorded by the falling of the shutter of the calling subscriber, which, in putting up the connection, is

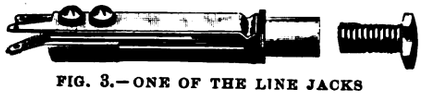

FIG. 3.—ONE OF THE LINE JACKS

FIG. 4.—A TRANSFER JACK.

FIG. 5.—ONE OF THE PLUGS

left bridged upon the circuit to be used as a ring-off drop.

The plug used is shown in Fig. 5, and is made of yellow brass, the tip of which is insulated from the body with hard rubber tubing. Between the connections at the base of the plug there is placed a fibre piece to which the connection of the switchboard cord is firmly lashed, taking the strain from the tinsel conductor. The handles are either of black rubber or fibre, have a shoulder turned upon the same to prevent slipping from the operator's fingers. The ringing and listening key (Fig. 6) is constructed upon a brass body casting, the mountings being heavy German silver springs and insulation of hard rubber, there being a dust-proof jacket fitting tightly over the same.

Immediately under the line drops in the drop panels there are located transfer drops (Fig. 7) which correspond in position with the transfer plugs and cords upon the section of board. Above the transfer jacks upon the jack panel are located order keys for calling the number desired to the distant board. This order key, which is illustrated in Fig. 8, is a brass casting within which are mounted German silver springs. The depression of the rubber button upon the same connects the two talking circuits of the two boards together, that is, the board upon which the order key is located and the distant board to which it is wished to communicate.

The transfer system which is used by

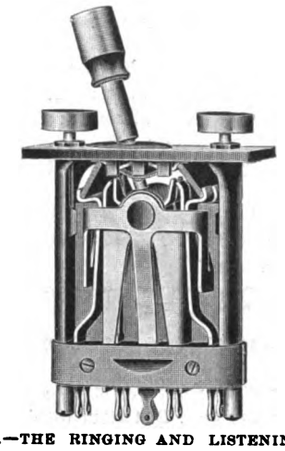

FIG. 6.—THE RINGING AND LISTENING KEY.

the Lafayette Company is what is called the Beach-Cook automatic transfer system. It is claimed to be the only automatic transfer system which independent telephone companies can procure. Its operation is as follows: Subscriber 5, calling upon No. 0 board, asks for 990. The No. 0 operator answers No. 5 with a short plug, placing the long plug of the same pair into the transfer jack leading to No. 10 board, depressing the order key at the same time connecting her talking circuit with No. 10 circuit, calling for 990. The insertion of the plug in the jack upon the No. 0 board automatically drops a shutter upon board No. 10, which corresponds with the transfer cord and plug which No. 0 operator wishes to be used in making this connection. No. 10 operator inserts this plug into jack 990, No. 0 operator calling the same by means of the push button upon the ringing and listening key in connection with the pair of cords upon her board. When the parties are through talking and ring off, this is recorded by the falling of shutter No. 5 upon No. 0 board. The operator immediately tests the connection, taking down the cords. This act automatically drops the shutter in connection with the cord and plug used upon board No. 10, which signals operator No. 10 that the parties are through talking, and to remove the connection.

Should either of the operators, however, through carelessness, remove the connection at one end and leave the same up at the other, there is in connection with this transfer system a hang-up drop and jack upon each board. Should the sub-

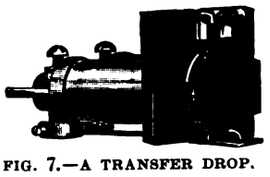

FIG. 7.—A TRANSFER DROP.

scriber who is left connected wish to call central, in doing so it will drop the drop upon the hang-up shutter, his own drop being shunted out by means of the plug in the subscriber's jack. The operator will answer this call by inserting the plug in the hang-up jack, thus learning what subscriber is hung up. Should the operator asking for a transfer connection be careless and allow a connection to be made with a busy telephone upon a distant board, the operator on No. 10 board can test in upon the connection by depressing a hard rubber button upon the transfer key corresponding with the cord and call the connection off by means of her order key to No. 0 board, requesting the No. 0 operator to take down the connection, as the parties are through. A diagram of the circuits of this transfer system is shown in Fig. 11.

The distributing board is located at the right of the switchboard, and is made up in strips 51 inches long, each strip accommodating 50 pair of wires. It consists of hard wood, hard rubber, black fibre, brass and German silver. The switchboard wires all terminate to the left upon each strip, the cable numbers to the right. The distribution or cross-connection is accomplished by means of short bridle wires, starting from the switchboard number, going to the rear and running from the horizontal or vertical lines to the strip

FIG. 8.—AN ORDER KEY

containing the cable number, coming through to the face at that point. It is a very complete, convenient and unique board.

The overhead construction of the Lafayette Telephone Company is good, being of No. 14 iron wire, the major portion of the plant being built upon 50, 45 and 40-foot poles, there also being some miles of 50-pair cable used. The instruments which are being used at the present time

Digitized by Google

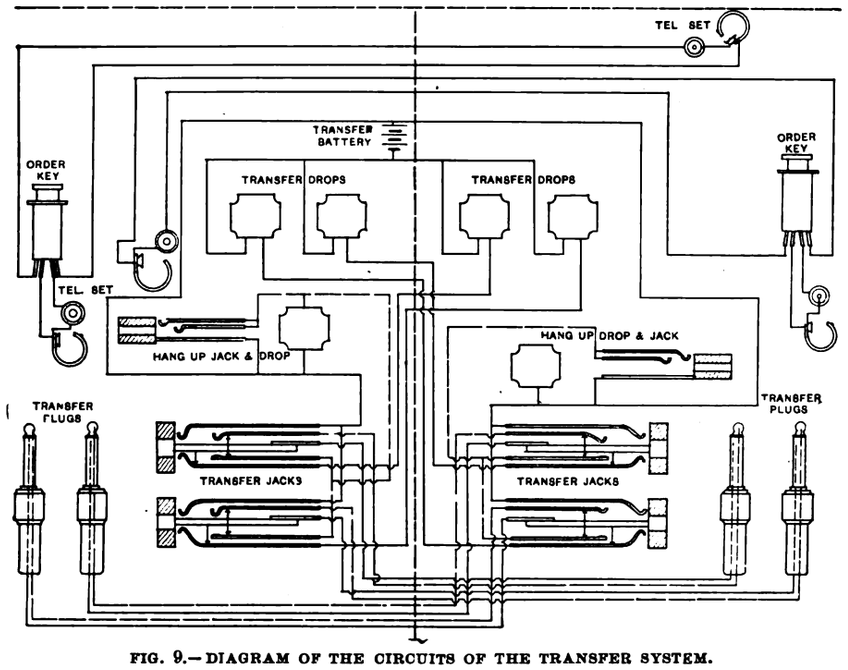

FIG. 9.—DIAGRAM OF THE CIRCUITS OF THE TRANSFER SYSTEM.

are assembled by the company itself, they purchasing what they consider the better portion of different instruments and assembling them as one.

The officers of the company are: Wm. Folckemer, President; Wm. Horn, Vice-President; Henry A. Taylor, Secretary and Treasurer; John F. McHugh, Counsel; Evan Shelby, General Manager; Directors, Wm. Folckemer, Wm. Horn, Henry A. Taylor, Leopold Dryfus and George P. Haywood.

## Among our Foreign Contemporaries

**A Direct Current Integrating Ammeter Without a Commutator.**—For registering the consumption of direct current there is now in use in this country practically only one meter, the Thomson recording wattmeter, even the Edison chemical meter having been quite completely displaced by the other instrument during the last few years. An ingenious meter for the same purpose in which there is no commutator and in which the friction of the recording dials is not a load upon the measuring device was recently described in "L'Industrie Electrique," the instrument being the invention of M. Blondlot. The general appearance of the interior parts of the meter is shown in Fig. 1, which, with a few words of explanation, makes clear the operation of the instrument. A and A are the coils carrying the main curent which passes in series with them through a suspended loop, B, hanging from a pivot, G, around which it is free to revolve. G and G′ serve as mercury cups to introduce the current to the movable coil without friction. Thus far the parts are similar to those of a Siemens electro-dynamometer, which this part of the instrument resembles in principle, the passage of a current tending to twist the movable coil into a plane parallel with that of the fixed coil. Attached to the spindle of the movable coil is an arm carrying a contact point, V, which strikes on the armature, R, of a magnet, E. When the coil, B, twists into the position to which the currents tend to force it, V closes a circuit through R and the high wound magnet, E, across the lines.

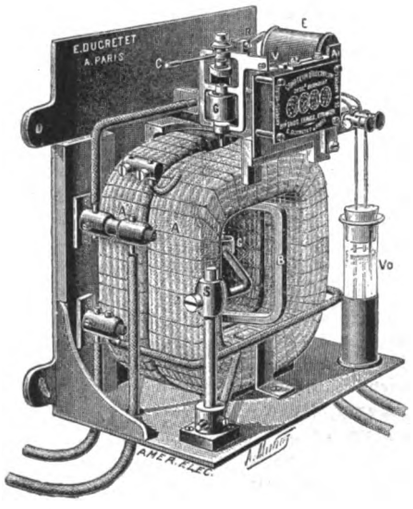

FIG. 1.—AN OSCILLATING COIL INTEGRATING AMMETER FOR DIRECT CURRENTS.

The magnet, E, then pulls up the armature, R, and with it the coil, B, and an impulse is given which throws the coil back toward the position shown in the figure. The coil is then twisted back again by the turning moment of the field set up by A on the currents in B, making another contact at V, getting another impulse from E and so on as long as a load is carried by the meter. The accuracy of the instrument as a measuring device depends upon the principle that the number of oscillations of the coil, B, in a given time is proportional to the square of the force which the coil, A, exerts upon it. As the current passing through both A and B sets up a magnetic force between these two coils proportional to its square, the frequency of the oscillation is exactly proportional to the current. In other words, the quantity of electricity passing through the instrument during the time of one oscillation is a constant, no matter how quick or slow that oscillation may be. All that is required, therefore, to make the instrument complete is a ratchet wheel, driving the recording dial and moved forward one tooth by every motion of the armature of the magnet, E. It is obvious that as the force between the fixed and movable coil is proportional to the quantity measured, the instrument could be used as a wattmeter by making either coil a potential winding. Sparking is minimized at the contact points by shunting a water resistance $V_0$ around the magnet.

---

**Fusing the Neutral of a Three-Wire System**—Puzzling questions have arisen in connection with the advisability or inadvisability of fusing the neutral wire of a three-wire system. There are pros and cons, but after due consideration the rules adopted in Germany state that the neutral wire of a three-wire system or of a multiphase system, as also any bare wires which are intentionally grounded, are not allowed to be fused. Mr. Hess, in the "Elektrotechnische Zeitschrift," however, now shows that a case may arise in which fire could be caused by the fact that fuses are forbidden under these circumstances. In the case he cites the neutral wire is insulated from the earth; a good ground occurs in one of the outside wires and outside of the main fuse of a consumer; in the inside of the building a branch of small cross-section, forming part of the neutral wire, becomes grounded; when these conditions arise a fire may be produced by the heating of this branch of the neutral wire. The current due to these two simultaneous grounds flows through no fuse except the one at the central station or at the transformer and this, being a main fuse, may be too large to cut out the circuit, especially if the current in the building is from a branch wire of small cross-section connected with the neutral. He, therefore, concludes that fuses on the neutral are quite necessary when the neutral wire is not well earthed. On the other hand, there are other difficulties which may arise if the neutral wire is fused; it is therefore a question of the choice of two evils, of which the above mentioned seems to be lesser, and even that case

Digitized by Google

can be avoided if the neutral wire is well grounded.

**The Board of Trade Panel.**—A peculiarity of switchboards of English traction power houses not found at all in American street railway plants is the Board of Trade panel, which is to English stations a feature resembling in appearance the total output panel of the American plant. The panel, or at least the instruments upon it, are to be found in all English railway plants, as they are required by what are known as the Board of Trade regulations. These require that the negative or grounded bus bar shall be connected with two special ground connections, independent of the rail returns, placed not less than 20 yds. apart and making such good grounds that an e. m. f. of 4 volts or less shall send through the earth from one to the other of them a current of 2 amperes or more. When these are connected to the negative bus, the current collected from the earth by them must not exceed either two amperes per mile of single track or 5 per cent. of the total current output of the station. Another requirement is that it should always be possible to reverse the direction of any current between the rails at any point and any pipe in the vicinity by interposing 3 Leclanche cells in series if the current flows from the rail to the pipe, or one Leclanche cell if the current flows from the pipe to the rail. Still another requirement is that the difference of potential between the most distant points of the rails and the negative bus bar must never be more than 7 volts.

A description of one arrangement of instruments on a panel designed to test these for requirements was recently given by Mr. J. Gray Scott in the London "Electrical Review," the diagram of connections being reproduced in Fig. 2. Here the two grounded plates specially provided for one test are connected to the two lower arrow-heads, which lead, as shown, to a double pole, two way dial switch at the lower part of the panel. By swinging the left-hand end of this switch up and the right-hand end down, a battery of two cells giving less than 4 volts is connected in series with the ammeter, $AM_2$ between the two grounded plates. According to the requirements given above, the ammeter should show more than two amperes. This test must be made at least once a month. Normally the dial switch is left with its right-hand end up, in which position the two grounded plates are connected in parallel through the recording ammeter, R A, with the negative bus bar. This ammeter is not what is usually called a recording instrument, but is better termed an integrating instrument in this country, but is really a recording instrument, giving a curve of the current at all time such as is obtained from a Bristol instrument.

Just above this dial switch is a cord and plugs and 6 plug sockets, one of which leads to the negative bus bar through the recording voltmeter, R V, while the others lead to distant rail points. This apparatus is for testing the requirement calling for a difference of potential between the most distant sections of the rails and the negative bus bar at all times

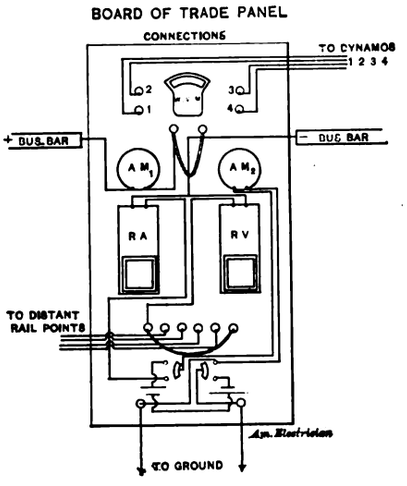

FIG. 2.—SCHEME OF CONNECTIONS OF BOARD OF TRADE PANEL.

less than 7 volts, a requirement which American traction systems would violate almost continuously. The other apparatus at the top of the panel consists of an ammeter and flexible cord for testing the leakage from the positive feeders, which is required to be less than 1/100 of an ampere per mile of track and must be tested daily or rather nightly when all cars are out of use.

**A French High Speed Vertical Engine**—The development of high speed engines has lagged in Europe far behind work in the same direction in this country, but

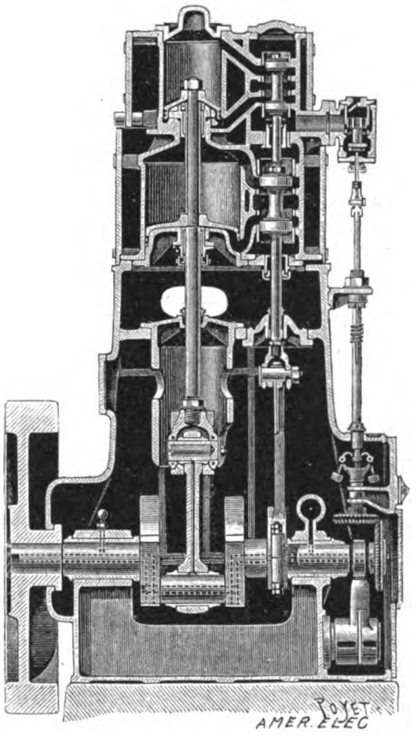

FIG. 3.—VERTICAL SECTION OF HIGH SPEED ENGINE.

some of the more recent designs show interesting details differing from practice here. "L'Electricien" describes a machine of this type designed by Messrs. Boulte & Larbodiere on the general principle of the English "Belliss" engine. A vertical section of the machine is shown in Fig. 3, in which it will be seen that the engine is double acting. The severe conditions of high speed service, notably the generation of heat at the main journals and the crank pin, as a rule render double acting engines out of the question for such work. In single acting engines the pressure is always downward upon the wearing parts and considerable play can be left in the brasses without pounding. If the engines are made double acting the brasses must be so tight to prevent pounding that they soon heat, and for this reason high speed engines are as a rule made single acting, whereby pressure is always delivered in one direction and the brasses can be left slack. Notable examples of such engines in this country are the Westinghouse and Willans. In the French engine, a vertical section of which is shown in Fig. 3, this difficulty is overcome by a novel and more efficient means of lubrication. This consists of a positive oil pump, shown attached to the right-hand end of the crank shaft, which delivers its oil into a passage through the shaft, cranks and crank pin themselves. This passage is shown by the dotted lines. From this central oil duct radial branches lead out to the wearing surfaces, journals and crank pin. Aside from this feature the design of the engine comprises a steeple compound arrangement of the cylinders with one gland between high and low pressure, cone pistons, piston valves, and speed regulation by means of a throttle valve controlled by a fly ball governor within the crank case. The rotating parts splash in oil and the case containing this oil is isolated from the cylinders and steam chests by means of an intermediate compartment open to the air, the piston and valve rod being packed both above and below this compartment. This allows any leakage of steam through the glands to escape to the air without entering the crank case, this feature resembling a similar arrangement on American horizontal high speed engines.

**A Magnetic Scale Collector for Electrolytic Baths.**—In the process of pickling forgings, plates and annealed steel parts to remove black oxide and scale a large amount of the latter material becomes detached from the iron, after which it gradually dissolves in the bath, using up acid that could otherwise be usefuly employed in cleaning the metal surfaces. The Cowper-Coles Company makes for use in such pickling baths a magnetic scale collector, consisting simply of a powerful magnet enclosed in acid-proof material. This, if placed in the lower part of the bath, quickly draws to it floating scale and magnetic oxide which by frequently lifting out the magnet can be readily removed from the bath. By this means a large amount of acid is saved.

**Loss of Light in the Enclosed Arc.**—In order to determine how much light was lost by the deposits formed on the inner globe of an enclosed arc, Messrs. Gerard and Bast made what appears to have been a careful series of tests of a 108-volt, 4.5 ampere enclosed lamp, one set of the tests being made when the lamp was started and the globe quite clean, while the second set was made after the lamp had been running 103 hours. Their results are given in decimal candles, which are practically equal to our candles, or more exactly one carcel is equal to 9.62 decimal candles. They measured the mean spherical illumination as also the mean hemispherical below the horizon. At the start when the globe was clean the mean spherical candle power was 168.8, the mean hemispherical 199.8, the mean watts per candle being 2.9 and 2.45 respectively. At the end of the test, when there was a deposit on the globe, these figures were 129.5 for the spherical and 157.6 for the hemispherical intensities, while the consumptions were 3.71 and 3.047 watts per candle respectively. There is, therefore, a loss of about 16 per cent. in the spherical intensity and 20 per cent. in the hemispherical. The total life of one set of carbons was 110 hours and therefore the second series of tests practically corresponds to the end of the life of a set of carbons. These results were published in "L'Eclairage Electrique."

---

**An English Switch.**—In England electric switches are comparatively rarely made of the knife and clip form so commonly used in this country, the contacts being as a rule of the laminated leaf type, similar to that used in General Electric circuit breakers. A new switch with this style of contacts and several other interesting peculiarities is shown in Fig. 4. The handle is attached through a quick break spring to a U-shaped piece, through which are passed several groups of laminated leaves, separated by distance pieces in order apparently to prevent them from crowding each other and to give increased cooling surface. The U-shaped piece is

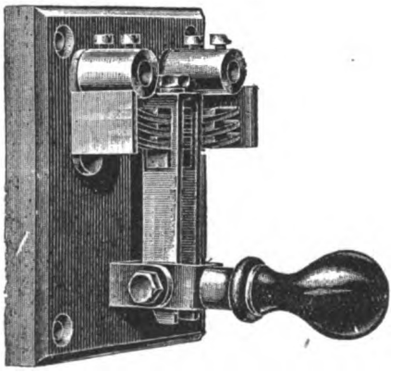

FIG. 4.—A MULTI-CONTACT SWITCH.

slotted in such a way as to allow the mechanical centering of the laminations between the contacts on either side. The laminations are readily removable and replaceable when burned out and the entire switch is made up of stampings so that it can be constructed at a low cost.

---

**A Storage Battery for Traction Service.**—A description of the street railway line of Ghent, Belgium, appears in the "Elektrotechnische Zeitschrift," which contains an interesting description of the accumulator used. Each car is equipped with 108 cells, weighing about 2 tons, sufficient to drive the car 35 miles on one charge, and with the schedule adopted, requiring charging twice a day. The cells are of the new Julien type, the peroxide of the positive being formed electrically. The positive electrode consists of a block built up of many horizontal layers of corrugated lead sheets. A view of this block appears at the left-hand side of the illustration, Fig. 5. The sheets are laid up with the adjacent corrugation at right angles to each other, so as to give numerous channels, and a large space to be filled by peroxide. The plates are burned together at the corners. This block is perforated with 9 vertical cylindrical holes through which pass 9 cylinders, forming the negative electrode, which is shown separately to the right-hand side of the same illustration. These cylinders consist of per-

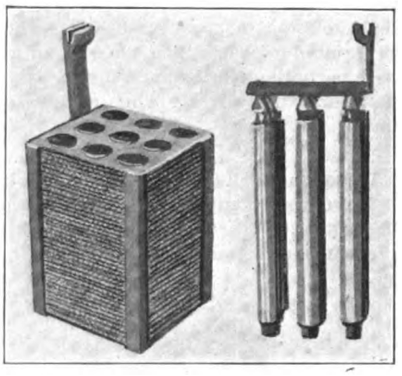

FIG. 5.—A NOVEL STORAGE CELL.

forated lead piping containing the negative active mass in the usual form of porous, spongy lead and of a volume bearing the correct proportion to the active mass of the positive. The negative cylinders are held out of contact with the positive block by means of perforated hard rubber insulating jackets. The performance obtained from this battery is as follows: A cell weighing 55 lbs., including acid, gave 300 ampere hours at a 15 ampere rate and 250 ampere hours at a 50 ampere rate. This high rate of discharge is due to the large surface obtained per lb. of positive material, but it would seem that this surface is quite inaccessible to the acid, and the battery would therefore require frequent rests during heavy discharge in order to allow the liquid to get into the recesses.

---

**A Circuit Breaker for Electric Cars.**—In an article on a German street railway system contributed by Max Schiemann to the "Elektrotechnische Zeitschrift," there is described a circuit breaker for use on cars, which is constructed on an ingenious principle which might prove valuable in other instruments. A view of it is shown in Fig. 6. The magnet coil ap-

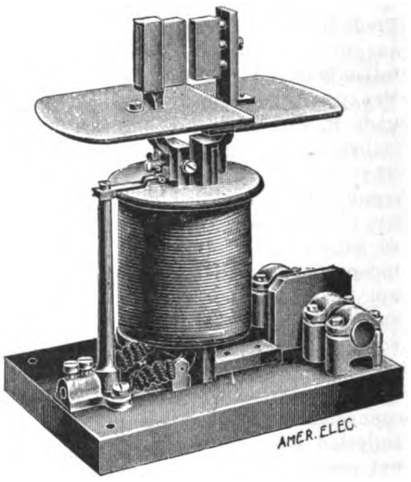

FIG. 6.—A STREET CAR CIRCUIT BREAKER.

pears in the center of the instrument and is evidently much more powerful than those designed simply to trip mechanical triggers of American appliances for the same purpose, the coil of the instrument having to accomplish all the work of opening the circuit by magnetic force. Passing vertically through the coil are two cores, one of which is fixed, while the other is hinged to the base. One of these carries a copper and the other a carbon contact at the top of the instrument above two protecting plates intended apparently to prevent the arc from striking downward. The opening of the circuit is accomplished when the current rises to such a strength that the two cores repel each other with sufficient intensity to overcome the restoring force. The beauty of the instrument is that the same coil that sets up the operating force delivers a field across the gap sufficient to blow the arc out sideways on the magnetic blow-out principle. This field is said to be sufficiently strong to render an opening of less than ¼ in. sufficient to break a 500-volt circuit carrying a street car overload.

---

**A Dynamo and Engine Clutch.**—The municipal electric light and street railway power plant at Plymouth, England, contains some interesting features, which were described recently in London "Engineering." The incandescent lighting is supplied by alternating currents and the two loads are carefully combined on the same engines so as to smooth out the load factor peaks of the two and make any engine useful on either the railway or the lighting system. This arrangement is practically the reverse of that common in this country; where, if traction and lighting are carried from the same station the two loads are carefully allotted to separate engines to prevent the fluctuations of the railway from disturbing the regulation of the

Digitized by Google

lighting. This disturbance is eliminated in the Plymouth case by the use of a substantial storage battery. As the plant is direct connected each railway generator is coupled to a lighting machine of the same capacity, 100 kw., and both are coupled to a 150 h.p. engine, which, it will be noticed, is only sufficient in size to drive either one of them. As it is proposed to run the lighting at times from the storage battery by means of the two machines used as a motor generator, they are both coupled to one end of the engine shaft, rigidly fastened to each other and connected to the engine through a clutch coupling. The latter is of an ingenious type, shown in Fig. 7. Here A is the driving member fastened through the whiffletree, C, with two helical springs encircling the boss of the driven member, B. These springs are of steel, rectangular in cross section and one is wound right-handed and the other left-handedly, so that one will drive in either direction, their other ends being attached to A in the upper part of the illustration. The collar, D, can be slid along the shaft by means of a jaw manipulated by the operator until it forces the shoe, E. This twists the whiffletree, C, until one or the other of the two steel straps takes hold of the boss, B, depending upon which way the shaft is turning. The friction tightens the strap just as does the friction of a rope upon the drum of a windlass or hoisting engine. By means of this clutch the two machines may be brought up to speed by the engine and afterward driven by the storage battery on the railway generator, the engine being uncoupled and stopped.

**An Overhead Conduit System of Traction.**—It has often been proposed to drive electrical omnibuses or other automobiles without rails on ordinary roads and supply them with power from an overhead trolley. In fact, such a system has been designed and put into experimental use in this country, involving two wires on which a small carriage or trolley is pulled along by a flexible connection from the vehicle. A proposed conducting system for the same purpose, consisting of an overhead conduit, is described in "The Railway World," the system being introduced by an English company. Fig. 8 shows the cross section of the overhead conduit proposed. It will be seen that it is supported from a suspension cable which can be given considerable sag, like that of a bridge cable, from the tops of poles placed at considerable distances from each other as compared with the ordinary trolley poles. The conduit is an inverted U-shaped structure of papier mache, supported at frequent intervals by wires and yokes from the suspension cable. Within this conduit and to either side are the conducting rails supported on insulators and on these rails run the wheels of a small four-wheeled carriage, serving as a trolley. This carriage is of course connected by a flexible two-conductor cable to the driven vehicle below with sufficient slack to allow the ordinary deviation of the vehicle from a straight path immediately below the conduit. Some such system offers a promise of satisfactory financial results in country districts, where the cost of a track would not be warranted by the amount of traffic.

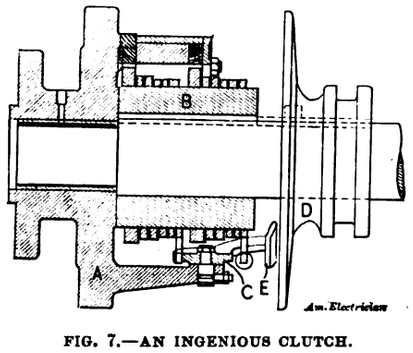

FIG. 7.—AN INGENIOUS CLUTCH.

**Contact Resistance of Carbon Brushes.**—In the elaborate serial on "Electric Generators," being published in London "Engineering" by Messrs. H. F. Parshall and H. M. Hobart, which, by the way, is by far the most complete and valuable work on the subject ever published, there recently appeared a discussion of the contact resistance of commutator brushes. A number of diagrams were given, of which one is reproduced in Fig. 9. This shows the remarkable fact that as the current density flowing across the face of the brush in contact with the commutator goes down the resistance of this contact goes up, so that the drop of voltage at this point is almost constant whatever the load of the machine may be within the limits of current density commonly used with carbon brushes. For instance, if the current flowing is 70 amperes per sq. in. the resistance of the contact is .0125 ohm per sq. in. and the drop is about .87 volt. If now the curent falls to 40 amperes the resistance rises to .021 ohm and the drop remains .84 volt, practically the same as before. This drop is that of one brush and must be doubled to give the total drop due to commutation. While the conditions of speed, brush pressure, etc., change somewhat this factor, the other curves given in the same article for other conditions coincide in character with that reproduced, but give higher values for the resistance, showing that the drop of the two brushes is at least 1½ to 2½ volts. This, it will be noted, must cause a serious impairment of the efficiency of 125 volt machines, this one loss being about 1½ to 2 per cent of the total output. The efficiencies of machies of higher voltages are affected to a lesser extent. The loss can be reduced in any machine over 90 per cent. by the use of copper gauze brushes as the lower curve shows.

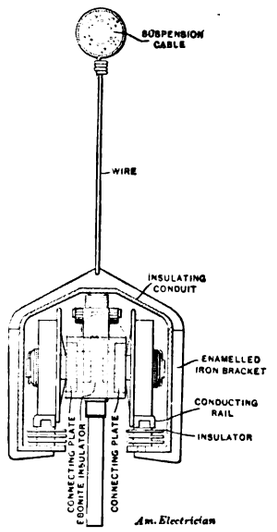

FIG. 8.—AN OVERHEAD CONDUIT.

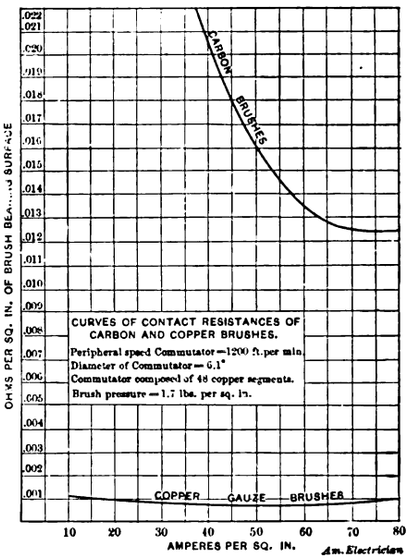

FIG. 9.—CONTACT RESISTANCE OF BRUSHES WITH VARIOUS CURRENT DENSITIES.

## NOTES.

**Anæsthetic Effects of Electric Currents.**—Mr. E. W. Scripture has published in "Science" a communication on the anæsthetic effects of high frequency alternating currents. It appears that with a current of about 28,000 alternations per second passing between the elbow and the hand a needle can be painlessly run into the forearm.

**A New Telephone Exchange in New York City.**—The New York Telephone Company opened on July 10th a new exchange known as the Madison Square, located on East 29th Street. The new office relieves the 18th and 38th Street exchanges, from which 1100 subscribers are gradually being transferred. This makes the fifteenth exchange of the company in old or lesser New York and the thirteenth on Manhattan Island.

**Street Railway Traffic Warranting Two Trolley Wires.** The traffic of the trolley cars over the Brooklyn Bridge is so heavy and the delay so serious in case of any failure of the conducting system that a

Digitized by Google

double trolley wire—not positive and negative, but both wires positive—has been put on the up grades. The bridge has a heavy grade from each terminal to the center. The cars coast down by gravity from this point to the terminal, so that the failure of the wire on the down grades would not stop the cars. In case either wire breaks the trolley can be transferred to the other.

**City Water Pumping in the Plant of the Niagara Falls Power Company.**—The wheelpit of the Niagara Falls Power Company is recessed at a level of about 120 ft. below head water, with 4 great arched chambers cut in the rock. One of these is occupied by the oil and air pumping auxiliaries of the turbines and generators above, and the others are to be occupied by 6,000,000 gallon water pumping engines, for the service of the Niagara Falls Water Company, which is allied to the Niagara Falls Power Co. This will do away with the steam plant formerly used for pumping the water and occasion a considerable reduction of the cost.

**The Use of Aluminum in Printing.**—It may not be generally known among electrical engineers that aluminum, now exclusively manufactured by an electrical process, is coming into extensive use in place of the lithographic stone for printing purposes. In fact, a new word, "aluminography," has been coined to correspond with lithography. Some of the advantages of the new material are briefly the following: Durability, greatly diminished weight and storage space, and the ability to use the plates in rotary presses, as they can be readily curved to fit a cylinder. Several makes of rotary presses adapted for this work are now on the market.

**Punchings for the Single-Phase Rectifier.** In answer to the request in the last issue of the American Electrician for offers of castings, laminae and other parts suitable for the machine the design of which was published in the June issue of the American Electrician, Mr. T. Binford, of 994 Washington Boulevard, Chicago, Ill., offers to make dies for the armature laminae if there appears to be a sufficient demand. Mr. Binford proposes to make the laminae according to the specifications for a dynamo or motor as outlined in one of the queries and answers on page 396 of the last issue of the American Electrician. Readers who propose to construct such a machine are requested to correspond with Mr. Binford direct.

**Graduate Courses in Electrical Engineering at the University of Wisconsin.**—During the coming college year a number of new courses, some of which are suitable for graduate work and bring a second degree, will be offered at the University of Wisconsin. These will be divided between four separate specialties, viz., electromagnetism and the construction of dynamos, alternating currents and alternating current machinery, applied electrochemistry and electrometallurgy, and electrical installations. The University faculty contains a number of the best instructors in these lines, particularly the second and third, in which fields Prof. Dugald C. Jackson and Mr. Chas. F. Burgess are respectively well known through their original work and publications.

**An Excursion of Electrical Engineers to Switzerland.**—The British Institution of Electrical Engineers this Summer holds its convention abroad in the form of an excursion to Switzerland. The proceedings open Saturday, September 2d, with a visit from Basle to the power station at Rheinfelden, followed by an inspection of the works of Messrs. Brown, Boveri & Company at Baden. Four days will be spent at Zurich reviewing the Oerlikon works and plants of interest. From this point the itinerary leads to Schaffhausen, Lucerne, Interlaken, the Stansstad-Engelberg and the Jungfrau three-phase mountain railways and other points, the last date scheduled in Switzerland being Saturday, the 9th. Several hundred members are expected to be present on the trip.

**The Cost of Municipal Lighting in Detroit.**—The fourth annual report of the Public Lighting Commission of the city of Detroit, Mich., for the year ending June 30, 1899, has recently been sent out. The report may be summarized as follows: The number of arc lights has been increased from 1744 to 1868, in addition to which there has been a reduction of the cost of operation and maintenance, bringing the cash outlay per arc lamp per year down to $46.46. The fixed charges are figured as they were last year, viz., depreciation at 3 per cent. and interest at 4 per cent. on the total investment less amounts already charged off and loss of taxes at the city and county tax rates on the assessed valuation of the plant. Thus computed, the fixed charges chargeable to the arc service amount to $29.10 per arc lamp, making the total cost to the city per lamp per year $75.56.

**The International Electrical Congress.**—In connection with the universal exposition in 1900 in Paris, there will be held an international meeting of electrical engineers and scientists, preparations for which are already under way. French electrical engineers have appointed a commission of organization for this congress, which is now circulating applications for membership. The well known engineer, E. Mascart, is the president of this commission. The subscription for membership is 20 francs. The meetings of the congress will last 8 days, beginning Friday, August 18th, 1900. The programme has been divided into five general divisions, as follows:

1. Scientific methods and instruments of measurement.
2. The production of electrical energy, transformers, transfer and distribution, electric lighting, traction.
3. Electro-chemistry, electro-metallurgy, accumulators, electric furnaces.
4. Telegraphy, telephones and various applications.
5. Electro-physiology.

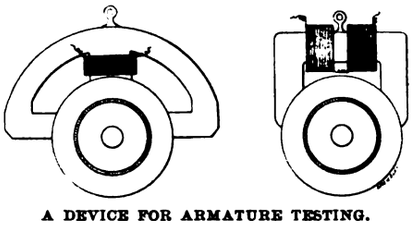
**The Cost of Exhaust Steam Heating.**—A report was recently made by Prof. J. E. Denton on a system of exhaust steam heating proposed by the Narragansett Electric Lighting Company, Providence, R. I., in which report many interesting figures in the form of estimates are contained, which may be abstracted in tabular form as follows:

| | |
|---|---|
| Volume of space to be heated | 25,000,000 cu. ft. |
| Estimated consumption of steam per hour, maximum | 110,000 lbs. |
| Average during winter months, per hour | 75,000 lbs. |
| Back pressure, maximum per sq. in. | 9 lbs. |
| Average | 6¼ lbs. |
| Increase in steam consumption of triple expansion condensing engines | 42% |
| In spite of an increase of the boiler pressure of | 50 lbs. |
| Cost of generating steam per 1,000 lbs. | $.19 3/10 |
| Total cost chargeable to heating | $ 20,615.00 |
| First cost of distributing system | 204,500.00 |
| 15% interest and depreciation | 30,675.00 |
| Cost of maintenance | 13,200.00 |
| Proportional share of interest and depreciation account of station cost | 16,500.00 |
| Incidentals | 8,775.00 |
| Profit, 20% | 10,530.00 |
| Proper income for steam sold | 63,180.00 |
| Square ft. radiator surface | 300,000.00 |
| Price per sq. ft. | $.358 |
| Estimated cost of heating by private boilers, including labor, per sq. ft. of radiating surface | .25 |
| Difference in favor of private heating per sq. ft. of radiating surface | .10 |

**The Westinghouse Company in England.**—Further details have been announced concerning the proposed plant for the construction of electrical machinery under the Westinghouse patents in England. A company has been formed, called the British Westinghouse Electric & Manufacturing Company, Ltd., with a capital of $7,500,000, of which $5,000,000 will be 6 per cent. preferred stock. The common stock will be taken by the parent American company in payment for its patents, good will, etc., while half of the preferred stock has been opened for public subscription to provide means for immediate expenditures in connection with the new plant, the remainder being reserved for future issue. A tract of about 100 acres has been secured in Manchester, on the banks of the ship canal. The buildings alone will have a floor area of 40 acres and will provide for the employment of some 5,000 men. The American company guarantees that the profits resulting from the business during the first two years will be sufficient to pay the 6 per cent. dividend upon the preferred stock. The prospectus of the new British company states that the net profits of the American company for the year ending March 31st last were more than $1,275,000, the value of the total output at Pittsburg being $7,140,000. The orders for Westinghouse apparatus in the United Kingdom and Colonies for the last year were given as amounting to $1,330,000.

**A Novel Selective Call System.**—Some of the Bell companies in the smaller towns are now installing a party line system having eight subscribers on one pair of metallic wires. For talking the

Digitized by Google



complete metallic circuit is used, but for ringing purposes one wire and the ground is used for four stations, the other wire and the ground for the other four stations. The subscribers' bells are polarized and so connected that a pulsating current in one direction over one wire returning through the ground will ring but two of the four connected on that wire, while a pulsating current in the opposite direction over the same circuit will ring the other two subscribers' bells. The four bells between the other line wire and the ground will be operated in a similar manner. At the central station a special motor-dynamo is used, from which can be obtained either an alternating current for ringing the ordinary bells or a pulsating direct current for ringing the party line bells in the system just mentioned. Whenever a ringing current is sent out over one of these party line systems two bells will always ring. Eight distinctive rings, one for each subscriber, are used. Two distinctive rings would suffice theoretically, but it is found more practical to use eight, as stated. At the switchboard there are four ringing keys, two for sending positive and negative pulsating currents respectively over one wire, and the other two for sending the same currents over the other wire, the ground being used in each case as the return circuit. As no device is used for locking out the subscribers not called, any subscriber may cut in at any time and overhear any conversation that may be taking place.

---

**A Steam Power Transmission Plant.**—An electric generating plant for supplying power for railways and mines in the Cripple Creek mining district in Colorado, very similiar to the plant of the Colorado Electric Light & Power Company in the same locality, described in the American Electrician of December, 1898, was officially opened on August 19th by the La Bella Mill, Water & Power Company. The power generating equipment is located in Goldfield, and like that of the other plant described above, is driven by steam power. The building is of masonry and steel and covers 10,000 sq. ft. The stack is of steel, self supporting, without guy wires, 12 ft. in diameter and 210 ft. high. The steam generating equipment consists of 6 Babcock & Wilcox boilers supported on steel girders over an ash tunnel and fitted with chain grate stokers. The coal is dumped from cars on an elevated track into inverted pyramidal steel coal bins hung from the roof. The flue runs through the basement to an economizer located under the pump room. The engine room contains an air compressor with a capacity of 5000 cu. ft. of free air per minute and three 750-h. p. cross-compound, horizontal Allis-Corliss engines direct coupled to General Electric three-phase alternators delivering 6000 volts direct from the machine windings with a frequency of 30 cycles per second. One common condenser is used of the elevated syphon type, with a cooling tower 110 ft. long, 20 ft. wide and 20 ft. high, mounted on an elevated piece of ground near the building. The whole plant is most carefully laid out, the steam and exhaust piping being minimized and other features thoroughly studied to obtain maximum economy and minimum depreciation. The work was in charge of Mr. L. L. Summers, who was retained as consulting engineer.

---

**A Simple Method of Testing Armatures.**—A means of very quickly and cheaply testing the insulation of armatures and instantly locating their faults, such as short circuited coils or wrong connections, is in use by the General Electric Company in the armature department at Schenectady. While the arrangement is of greater value to manufacturers than to consumers of electrical apparatus, it might well be adopted by street railway companies for motor testing and by large dealers for the testing of second-hand machinery. The test does not require the running of the armature, the internal electromotive forces being set up by simply generating an alternating field of force through it. The apparatus is shown in the accompanying sketch, the two figures being two different forms, one bipolar and the other what might be called a tripolar arrangement. The armature can be brought into position in any convenient way, under a magnet shown in the figure, which may be supported by a rope and counterweight. This magnet is of laminated iron and is wound with a coil excited by alternating currents. When energized it sets up internal electromotive forces in the armature conductors, which spread throughout the winding, tending to break down any weak points between the windings or segments of the commutator. A short circuited coil will be burnt out almost instantly. By giving the armature a part of a turn and repeating the process two or three times the whole armature can be thoroughly tested within a moment's time. The test is in its way a severe one, as the internal electromotive forces can readily be made much higher than those which the same armature can possibly generate when running as a part of a dynamo. If the magnet is of sufficient size to saturate the armature core and the frequency is 133 cycles per second, the electromotive forces set up will be much greater than the armature windings themselves can generate at the much lower frequency at which direct current machinery as a rule operates. The apparatus in either the two or three-pole form and with these poles located at any angles can be used on any continuously wound armatures except those designed for multipolar machines and fitted with special internal cross connections between points of equal potential. Since all the lines of force which enter the winding must leave it again, they set up balanced electromotive forces in simple continuous windings which would be short circuited by internal cross connections unless such armatures were provided with special testing magnets with poles corresponding in angular dimensions to those of the fields in which they are designed to run.

A DEVICE FOR ARMATURE TESTING.

---

**A Difficult Piece of Track Conversion** — There is now in course of construction on a section of Broadway, New York City, an open conduit track, the work on which is about as difficult an undertaking of its kind, outside of switches and crossings, as can be imagined. The Metropolitan Street Railway Company has had in use for a year and a half on this section its standard underground trolley track with control conduit and slot. The Third Avenue Railway possesses a right of way through the same street. To operate the latter company's line electrically and by the independent power system of the latter company, a separate pair of power rails in a separate conduit are needed. The existing conduit is therefore being pushed over to one side to give room for the other conduit beside it between the track rails. The difficulties are introduced by the fact that the track is being kept in service for the Amsterdam Avenue cars with a headway of about two minutes, and the conductor rails must, therefore, be kept "alive" throughout the progress of the work. The line runs all night, so that there is no opportunity to work while it is shut down. The change is accomplished as follows: The pavement is first removed and the heavy concrete foundation and conduit wall is broken up and removed piece by piece from around the yokes and live conductor rails, the track being shored up meanwhile to carry the heavy double truck cars which constantly run over it. Temporary wooden yokes are then inserted to maintain the gage of the track rails and the old yokes are loosened from them and pushed to one side, carrying with them the old slot rails, insulators and conductor rails. The conductor rails are then removed in single rail lengths and the free ends are fitted with outwardly flaring slippers to prevent the shoes on the plows of the cars from being carried away, the cars being allowed to drift through this open section. The old yokes are promptly removed and replaced by new ones fitted with appertures for the two conduits symmetrically placed between the track rails. The track as completed has only one pair of tramrails carrying the cars of both lines, the plows of one company going into one conduit to one side of the track center and those of the other company into the other. The work is constantly attended by shocks, short circuits and violent arcs, but the men become accustomed to these features and do not seem to mind them.

### Synchronizing Lamps at the Engine.

In the operation of paralleling alternating current dynamos the adjustment of a fresh machine, just started up, to exact synchronism with those already carrying the load cannot be accomplished entirely at the switchboard, but, as a rule, requires the assistance of a man stationed near the engine. Some engines specially designed for alternating current dynamos are fitted with attachments by which the speed at which the governor tends to hold the engine can be varied up or down a few revolutions, but as a rule these are not necessary, and a fresh machine can be synchronized by simply manipulating the stop valve. This is due to the fact that the governor tends to allow the engine to run light a little faster than the others which are running with their load, since all governors in use on such services must slow down their machines as the load increases. This slight excess of speed can be readily shaved off by nearly closing the stop valve.

The assistance of the engineer in adjusting the engine to just the right speed is best guided by synchronizing lamps so located that he can see them. In direct coupled plants, as a rule, the switchboard is within plain sight from the engineer's position at the stop valve, but in belted plants—especially where the engines are on one floor and the dynamos on another—this is not the case. In one plant in New York City a lamp is placed in the engine room and connected to a plug on the end of a flexible cord hanging over the top of the switchboard upstairs. When a new machine is to be started one of the synchronizing lamps on the panel of that machine is removed and the plug is put in its place. The lamp down in the engine room then becomes one of the synchronizing lamps, the other remaining in operation on the switchboard to inform the switchboard attendant when to close the switch.

This device is a very effective one and constantly used, but is rather slipshod for regular switchboard practice. The same result might be obtained with permanent wiring by using a multi-pointed dial switch of the type commonly used for transferring a voltmeter from circuit to circuit, the switch being properly wired to the engine room lamp and to the synchronizing transformers of each machine.

### Heating by Means of Exhaust Steam.

One of the severest trials of central station men, especially in the large cities, is the isolated plant which does the lighting and motor work of the largest and in many ways the best consumers. The competition of the isolated plant exists almost entirely because of the use in connection with it of exhaust steam for heating. It is argued, and correctly, that the steam must be generated throughout the greater part of the year and might just as well be used for driving dynamos—supplying the lights and running the motors—on its way between the boilers and the heating system. The coal consumption is not materially affected, a certain amount of labor is required in either case and the added cost of the complete plant is less than the charges of the central station for the same service. If the central station were in a position to supply the exhaust steam for heating as well as the power for lighting and motors it would, when favorably located near a business center containing several office buildings with such plants, be able to add greatly to its motor and lighting load, as well as obtain a revenue for an otherwise wasted by-product, exhaust steam. It is hard for the central station contract manager to prove to the owner of a proposed building that the station can light and run its elevators for less than it would cost an isolated plant to run over and above the cost of heating, but it is comparatively easy to compete with the more definite figure of the total cost of running an isolated plant. Such business is, as a rule, profitable at comparatively low rates, owing to the fact that it is concentrated among a few comparatively heavy consumers, easy to reach electrically and to collect from financially, as compared with widely scattered small loads.

A factor which should often be considered in the rates to be charged for exhaust steam is the increased consumption of the engines per horse-power hour. A report on a proposed district steam heating system of Providence, Rhode Island, appears on another page of this issue, according to which the change from condensing to an average back pressure of 6 lbs. gage would increase the steam consumption of high economy engines 42 per cent. over and above any incidental saving and in spite of a considerable increase of the boiler pressure. There appears to be very little published information on the subject of the effect upon steam consumption of a variation of the back pressure, but what there is points to results comparable with this estimate. Theoretically, the change of the back pressure from 2 lbs. absolute to 6 lbs. above the atmo-

Digitized by Google

sphere would nearly double the steam consumption of a theoretically ideal engine taking steam at a boiler pressure of 150 lbs. The reason for this effect can readily be understood by considering an indicator card, in which a change from condensing to non-condensing cuts off about 13 lbs. of the effective pressure the whole length of the stroke, which must be made up by a considerable increase of the length of the admission line. The argument is advanced by some of the advocates of exhaust steam heating that this is easily compensated by raising the boiler pressure the same number of pounds as the back pressure is raised, which is generally an easy thing to do. This argument is entirely wrong, as a little consideration of an indicator diagram will show. The same mean effective pressure must be maintained if the same work is to be done. If the back pressure for the whole length of the card is raised 20 lbs., the forward pressure must be raised on an average the same amount. If the initial or boiler pressure is raised 20 lbs., the cut-off remaining the same, the expansion line will come down at release to within a few pounds of the old expansion line, and the needed m. e. p. will not be obtained. As a rule, to maintain the same consumption of steam with the increased back pressure given above, the initial pressure, if 100 lbs., must be raised to about 150, and if 150, must be raised to about 250. Even this requires a greater fuel consumption, as less water is evaporated per pound of fuel at the higher pressures, and as a rule the whole boiler and engine equipment would have to be altered for such a change.

---

It may be safely estimated that a change of the back pressure from a condenser vacuum to that required for district heating will increase the steam consumption of an engine, if it is single expansion and has a low boiler pressure, by at least 100 per cent., and if it is compound and has a higher boiler pressure, at least 50 per cent. It is therefore unsound to argue, as is commonly done, that no part of the cost of the fuel should be charged to the exhaust steam heating, since, as is commonly argued, the steam is required in any event for the engines. If, on the other hand, all of this increased amount of exhaust steam is required for heating and the charges therefor are made to cover the cost of all the fuel, the effect on the engine efficiency of course makes no difference whatever.

**Motor Driven Centrifugal Pumps.**

The customary methods of pumping water by means of electric power involve as a rule more or less complicated electrical controlling and regulating apparatus for obtaining the proper pressure or flow under different demands, which apparatus may be largely done away with in many instances by combining suitable pumps with properly wound motors. As a rule the pump is required to maintain constant pressure with a variable flow, a requirement to which the positive action or piston type of pump at constant speed is by nature most poorly adapted. In water-works, hydraulic elevator or ordinary house service, the control is, as a rule, obtained by using a tank or pneumatic accumulator and stopping and starting the pump, or worse, opening and closing a bypass by means of a float controller.

---

The advantages of centrifugal pumps for such service do not begin to be appreciated as they should be. A centrifugal pump maintains a nearly constant pressure when run at constant speed over a wide range of flow, from zero discharge up to its capacity. This action can perhaps best be described by a reversion of the old time analogy between the flow of water and that of electric current. Just as a shunt-wound dynamo, when driven at a constant speed, tends to lift an electric current, so to speak, through a practically constant number of volts, whatever the number of amperes passing through it may be within its capacity, so a centrifugal pump tends to give to the water passing through it a nearly fixed difference of pressure whatever the number of gallons per minute may be. This action is quite different from that of piston pumps, which, when run at constant speed, raise the pressure higher if the delivery is impeded so as to force the same amount of water through it, and which, if the reduction is sufficient, compel some part of the electric or hydraulic system to break down.

---

Like the dynamo, the centrifugal pump absorbs less power as the flow through it is checked, the analogy failing if the flow is reversed, as the purely centrifugal pump will not become a water motor. Also like the dynamo, there is a drop of pressure due to internal friction or resistance with increased demand, which with ordinary pumps amounts to about 20 per cent. between no discharge and that of maximum efficiency. On account of the increased load with increased demand the motor may be readily differentially wound so that as the discharge increases the speed runs up to maintain the water pressure constant.

---

On account of this property a centrifugal pump may be used to give a constant head to a system of piping without the use of a storage tank and will maintain its pressure under great variations of flow. The domestic water supply of Bakersfield, California is obtained by means of pumps driven by induction motors, which discharge directly into the mains, with no water tower, maintaining the proper head of 35 to 40 lbs. per sq. in. over wide variations of the flow allowed through them by the opening of consumers' taps. In many isolated plants there are motor driven pumps for maintaining a water service throughout the building or district served, the belts, gears, tanks, float valves, controllers, pistons and general complication of which could be entirely done away with by the substitution of small centrifugal pumps direct coupled to the motors. On account of these complications direct acting steam pumps with their excessive fuel consumption are generally used for small or intermittent work, the steam pump having the advantages of simplicity and partial automatic regulation of water pressure delivered lacking in the motor driven piston pump.

---

At its best the centrifugal pump is rarely as efficient as the more complicated piston pump and its efficiency falls off rapidly with reduced flow, yet the inefficiency of belts or gears required for motors driving piston pumps and the losses involved in frequent starting and stopping may bring down the efficiency of the piston and motor combination to that of the direct coupled centrifugal set. When a bypass is used with a piston pump, the machine running constantly, part of the time against the load and part of the time free from it, but subject to all the internal losses, the efficiency of the piston pump is reduced, as it is also when the flow is varied by slowing down the motor by means of resistance. If the bypass is used as a leak, the pump being kept under pressure all the time and its flow adjusted by varying the opening of the bypass—as is done in some central stations where boiler feed pumps are driven by induction motors of which the speed control is difficult—the efficiency naturally falls to very low values under light deliveries.

## SIMULTANEOUS TELEGRAPHY AND TELEPHONY AND THE CONSTRUCTION OF APPARATUS THEREFOR.

BY H S. WEBB.

The transmission of telegraph and telephone messages over the same wire at the same time is called simultaneous telegraphy and telephony. Before describing the methods of arranging the telgraph and telephone apparatus by which this simultaneous transmission can be accomplished it will be well to consider briefly some of the fundamental principles involved. Fig. 1 shows the connections for the ordinary Morse closed circuit system as used in this country for manual transmission of telegraph messages. Suppose the average speed is 25 words per minute, or about five signals per second, that is the current in the line increases from zero to its maximum value, remaining at this maximum value for less than one-tenth of one second, and then decreases again to zero, remaining at zero for about 1/10th second. This is repeated at the rate of about five times per second. The time required for the current to increase from zero to its maximum, or vice versa, will depend upon the relative values of the self-induction, electrostatic capacity and resistance of the line wires and apparatus.

It has been shown that in a circuit having negligible electrostatic capacity the time for a current to reach its maximum value increases as the ratio of the inductance to the resistance, i. e., T varies as L/R. So that in an overland telegraph circuit in which the electrostatic capacity is very small, the time required for the current to reach its maximum value can be increased by increasing the ratio L/R, and, of course, L/R is increased by increasing L or decreasing R, or both. We can easily increase L/R, but, unfortunately, with a given circuit we cannot increase L without increasing R somewhat.

Suppose we have a simple short overland telegraphic circuit, as shown in Fig. 1. When the key is closed to send a signal over the wire, the current will rise to its maximum value almost instantaneously and fall to zero again almost instantaneously when the key is opened. The current curve will be somewhat like that in Fig. 2, in which time is plotted along OT and the corresponding current in amperes along OI. The time required for the current to reach its maximum even on an overhead line 350 miles in length is less than 1/40th of the duration of a dot. If it is desirable to increase the time insert in the circuit some inductance, that is, a coil of wire wound over a soft iron core. Then the circuit would be as in Fig. 3, in which I and $I_1$ are two impedance coils. Now the inductance in the coils I and $I_1$ acts as a barrier to the inrushing current and prevents it from reaching its maximum value as quickly as before; the larger the ratio of the total inductance to total resistance in the circuit the more gradually will the current rise to its maximum value. Coils having inductance and used for this purpose, are called choke, retardation or impedance coils, because they choke, retard or impede the current.

The reason for this is usually explained as follows: The current in the coil creates in the iron core lines of force which increase as the current increases. This increasing of the number of lines of force generates an opposing or counter electromotive force proportional at each instant to the rate at which these lines are increasing, and, consequently, the resultant electromotive force, and, therefore, the currents reach their steady maximum values gradually and not instantly. Now the induction increases as the square of the number of turns in the coil, and the resistance increases about as the number of turns, from which it is quite evident that L/R increases rapidly as the number of turns increases.

Now when the circuit is broken at the key the rapid decrease in the lines of force threading the iron generates an electromotive force; but this time it is in the same direction as the original electromotive force, and, therefore, tends to resist the sudden decrease of the current, and, therefore, the current decreases gradually until the spark disappears, when it drops to zero instantly.

To make the increase and decrease in the current still more gradual two condensers, C and $C_1$ are connected in the circuit as shown in Fig. 4.

Now C and $C_1$ must become fully charged before the current in the line can reach its maximum value, and thus the rise of the current in the line to its maximum value is delayed, and, upon opening the key, the condensers tend to discharge their current into the line in the direction of the original current, thus causing the current in the line to decrease more gradually to zero. The current curve in the line can be made to approach the curve in Fig. 5 by using proper impedance coils and condensers.

At the rate of 25 words per minute there would be about 5 dots and spaces per second, or five curves like those in Fig. 5.

The induction coils and condensers will necessarily interfere with the use of any rapid automatic system of telegraphy, because the signals would be of such a short duration that there would not be time for the current to reach its necessary maximum value or to return to zero before a succeeding signal would be sent giving a curve somewhat like that in Fig 7. This

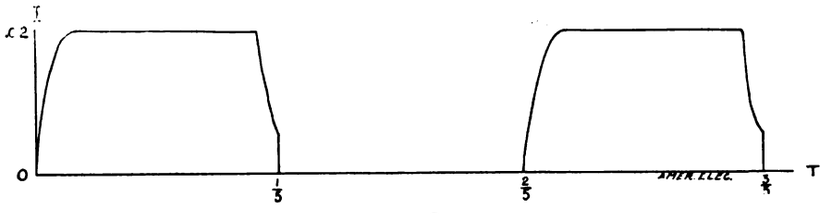

FIG. 2.

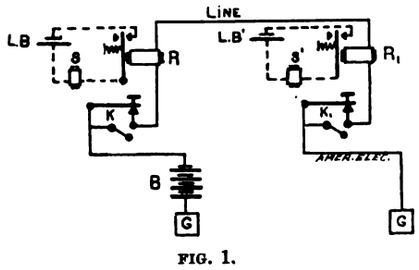

FIG. 1.

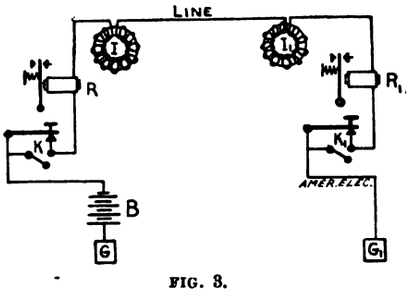

FIG. 3.

message was made by a submarine cable syphon recorder, and such a current would not work a Morse relay properly. Moreover, even if suitable relays could be used, such rapid signalling would seriously interfere with what we are striving for, namely, to telephone as well as to telegraph simultaneously over the same wire. About the lowest audible musical sound is produced by 15 complete vibrations per second. Therefore, an undulating current which changes at such a low rate that it would never cause the diaphragm of a telephone receiver to move as fast as it would be moved by a current having a frequency of 15 periods per second, would produce no sound, not even a click, in the receiver.

Now if a telephone receiver, TR, with its induction coil, S, be connected to the circuit, as in Fig. 8, the telegraph current would go through the receiver circuit to earth in preference to passing through the line and through the distant impedance coil and relay, because the receiver circuit offers so much less resistance to the steady or slowly increasing and decreasing currents. And even if no sound was produced in the receiver still it is necessary, in order that the telegraph signals sent from station A shall affect the relay at station B, to prevent the telegraph current from passing through the receiver. To accomplish this a condenser is connected between the receiver and the line as shown at $C_2$. Fig. 9. It is a well known fact that a condenser will not allow a continuous current to pass through it, because its resistance to such a current is practically infinite. Therefore the telegraph currents will not pass through it, and, although it charges and discharges when telegraph signals are being sent, causing the receiver diaphragm to be moved to and fro, still the rate of change of the current is too slow to cause an audible sound in the receiver, as previously explained.

It has now been shown that the telegraph signals do not affect the telephone receivers. It then remains to be shown that telephone currents sent from station A will operate the telephone at station B, but will not interfere with the telegraph signals at A or B. In ordinary conversation 300 complete vibrations or periods per second is about the average frequency of the sound waves. By talking into a telephone transmitter, therefore, an alternating electromotive force is generated in the secondary of the induction coil whose average frequency is 300 periods per second. This rapidly alternating electromotive force in the secondary coil will charge and discharge the condenser, producing in the line wire an alternating current similar to that in the ordinary telephone line, as shown in Fig. 6. In Fig. 10 let curve A represent the slow undulatory telegraph signal current and B the rapid alternating telephone current. In the line these will be superimposed upon each other, producing a resultant from curve C, Fig. 10.

But why do not these rapidly alternating charges and discharges go to ground through the home telegraph apparatus and interfere with the telegraph signals, instead of operating the distant telephone? In the first place, even if all the telephone current did go through the home telegraph apparatus, it would not affect the signals, for the telephone current is probably less than 1/5000 as large as the telegraph current, so its effect upon the relay would be insignificant, as is evident from curve C.

Now, practically the whole telephone current will go over the line and through the distant receiver for the following reason: It is a well known fact that a circuit containing inductance offers greater resistance to the flow of an alternating current than to a direct current. The resistance of a circuit to the flow of an alternating current is called its impedance. For a continuous current $I = E/R$, but for a simple alternating current

$$I = \frac{E}{\sqrt{R^2 + (2\pi n L)^2}}$$

in both of which expressions I = current, E = electromotive force, R = resistance of whole circuit. $\pi = 3.1416$, n = number of double vibrations or periods per second, L = inductance, in henries, of the whole circuit. The expression

$$\sqrt{R^2 + (2\pi n L)^2}$$

is called the impedance. Now it is evident from this last expression that the impedance increases with the frequency n, and the inductance, L.

Suppose we calculate the impedance of a 500-ohm choke, or impedance coil. One that I made has an inductance L of about 8 henries for a current of 0.013 amperes, and if N = 300 periods per second then $2\pi n L = 15120$ and $\sqrt{R^2 + (2\pi n L)^2}$ = 15128, that is, the impedance of this coil is over 30 times as large as its resistance for a periodicity of 300. The impedance of a 250-ohm secondary coil is about four times its resistance. But the condenser in the telephone circuit tends to reduce the impedance of that circuit and therefore its impedence would probably be less than 1000. In the circuit with the 500-ohm coil there is also the relay, so that the total impedance of the telegraph circuit at one station in Fig. 9 is probably more than 50 times as great as that of one receiver circuit, and, therefore, most all the telephone current will pass through the line and the other telephone. To insure more satisfactory results the number of retardation coils and condensers are usually greater than shown in Fig. 9, and the circuits are arranged as in Fig. 11. I have also found it advantageous in some cases to connect a condenser of one or two microfarads capacity around the telegraph key and relay, as shown by the dotted lines in Fig. 11. This figure gives a complete diagram of connections for one complete metallic telephone circuit and two telegraph circuits over one pair of line wires, the ground being used as a return for the two telegraph circuits. The method so far described was invented and developed by Van Rysselberghe, an official of the Belgian telegraph service.

M. Cailho, a Frenchman, has devised

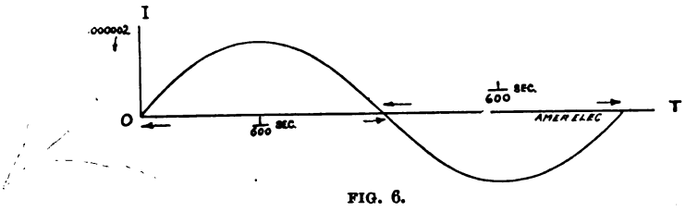

FIG. 6.

FIG. 7.

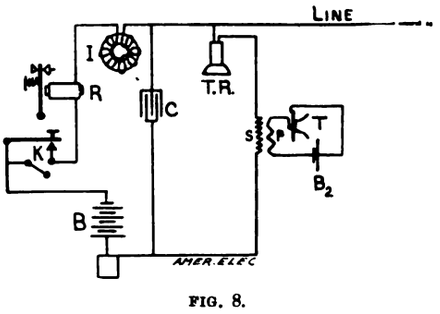

FIG. 8.

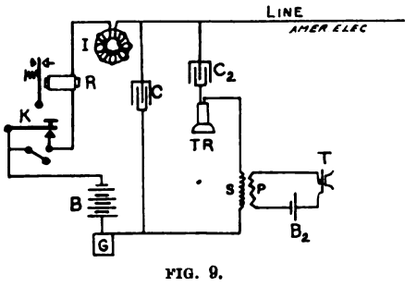

FIG. 9.

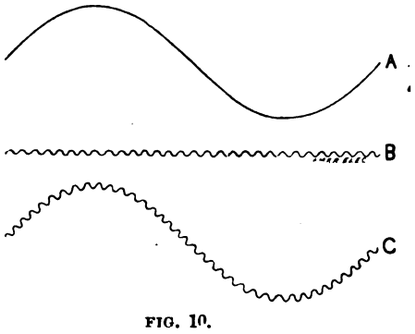

FIG. 10.

Digitized by Google

a method whereby the two line wires forming one complete metallic telephone circuit are connected in parallel for the telegraph circuit, using the ground for the return telegraph circuit. In this method, which is much simpler than Van Rysselberghe's, only one telegraph message instead of two messages, as in the preceding system, can be sent over the two wires. M. Cailho's arrangement is shown in Fig. 12.

The coil A B consists of two identical

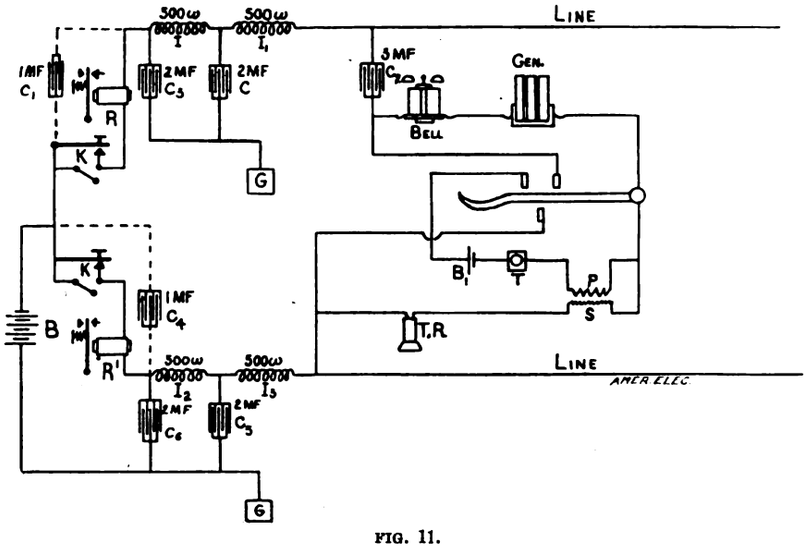

FIG. 11.

windings, A and B each having exactly the same resistance and the same number of turns and wound on the same soft iron wire core. This arrangement is similar to the bridge duplex telegraph system used on submarine cables. The telegraph currents divide at the point F into two equal parts, since the two paths have equal resistance, and pass through the two windings in opposite directions, so that the two coils tend to magnetize the iron core equally but in opposite directions, and, consequently, the self-induction will be practically zero, and the impedance to the telegraph circuit will be no larger than the ohmic resistance. For the telephone currents, however, the case is different. For the telephone currents would pass through the two halves A and B in the same direction and, consequently, the impedance offered by the coil to the telephonic current would be very large, thus practically forcing all this current through the telephone where it belongs. Thus the coils prevent the telephone currents from passing through them, but they do not interfere with the telegraph signals.

M. Cailho has successfully used coils of lower resistance, but the induction was made high. It is said that Morse relay magnets having a resistance of five or six hundred ohms may be used in place of the special coils. In this case the point F in Fig. 12 would be the junction of the two coils of the relay magnet. This method has the advantage that condensers are not absolutely necessary, and the extra apparatus needed is very much simpler than in Van Rysselberghe's method. Furthermore, the talking qualities of the telephone are not interfered with in the least and either regular series or bridging telephone bells may be used. If care be taken that the two halves of the coils A and B have exactly the same resistance and number of turns and the two line wires be reasonably equal in resistance, I have found that the clicks in the telephones will not seriously interfere with talking, although they may be heard. However, if the clicking is found objectionable it may be almost entirely obliterated by connecting condensers of one or two microfarad capacity around the telegraph relay and key at each station, as shown in Fig. 12. This system has been quite extensively used in France.

Of course in Van Rysselberghe's method two telegraph circuits can be operated over one pair of telephone line wires, or, by using the earth as a return for both telephone and the telegraph currents, then over a single wire, both the telephone and telegraph may be operated, while in Cailho's method over a pair of line wires there is only one telegraphic circuit in addition to the telephone circuit. In both systems high-resistance telegraph relays (150 ohms or higher) should be used, and in Van Rysselberghe's method half the necessary batteries should be located at each end. It will require 50 volts or more, depending on the line resistance, to furnish 20 milliamperes for the telegraph relays. Although I have not had the opportunity to try it, I believe that in Van Rysselberghe's method telephone induction coils having more turns in the secondary, say 500-ohm secondary coils, would work better than the ordinary 250-ohm secondary coils.

For the benefit of those who may desire to make the coils and condensers themselves, I will give here some directions which may be of service.

The two five hundred ohm impedance coils necessary at each end of the line in Van Rysselberghe's method may be wound upon one iron core, in which case care must be taken to connect the two windings to help and not to oppose each other. Practically this makes one coil of 1000 ohms resistance, with an additional terminal brought out from the middle of the coil. It may be made of No. 30 B. & S., double cotton-covered copper wire, requiring 9681 feet or nearly 3¼ lbs. for each 1000-ohm coil. No. 32 B. & S. wire would also do.

The core should be made of a bundle of soft iron wire, any size from No. 20 B. & S. to No. 25 B. & S. About 2 lbs. will be needed, and it must be cut up into pieces about 17 inches long. The middle five inches should be wrapped with linen or other insulating material, and two discs of cardboard, or, better still, wood or fibre, slipped on to form the ends of the spool, and securely fastened in place, leaving five inches between them for the coil of copper wire. Fig. 13 is a cross section of the completed coil.

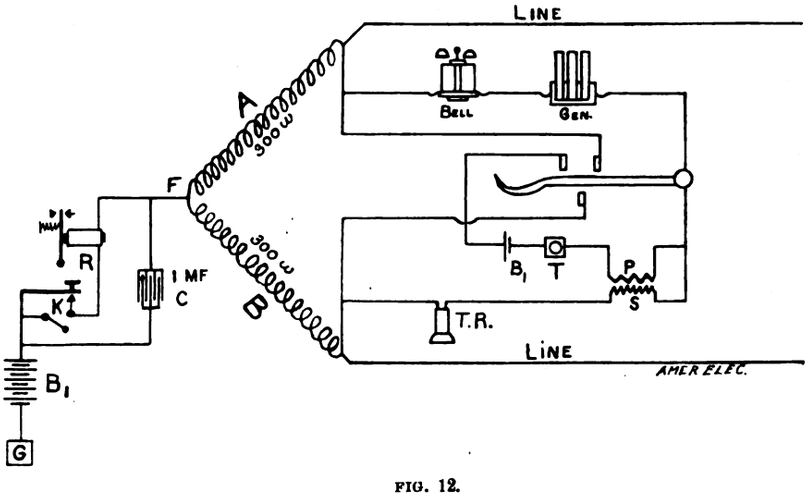

FIG. 12.

After winding on the 1000 ohms of wire the coil should be wrapped with linen and both ends of the iron wire core should be bent around over the coil, making the iron circuit as complete as possible in order to get the maximum inductance.

The coils for Cailho's method can be made in the same way. It will require

Digitized by Google

about 1¾ lbs. of soft iron wire and 2 pounds of No. 30 B. & S. double cotton-covered wire for each coil of 600 ohms. The iron wire should be cut into 12-inch lengths, and the distance between the discs should be about 3½ inches. Two wires should be wound on together to insure having the same number of turns and resistance in each half. The outside terminal of the one coil should be connected to the inside terminal of the other. The winding should be wrapped with linen and the iron wire bent back over it, as described for the preceding coil. The iron core can be slipped into the lathe chuck and the copper wire wound directly on the insulated portion, or the coils could be first wound on spools made of thin wood or fibre and then slipped on the iron core. These coils could also be wound with No. 32 B. & S. wire.

### THE PARAFFIN PAPER CONDENSER.

The condensers may be made of alternate layers of paper and lead foil (which is cheaper than tin foil). Every alternate sheet of lead foil should project beyond the paper on one side and be joined together, the remaining sheets should project on the opposite side and be joined together as shown in Fig. 14. It will be well to make the condensers of one microfarad capacity each, and if more than one microfarad is required simply join the requisite number in parallel.

The capacity of a plate condenser in microfarads may be calculated from this formula

$$C = \frac{k \times s}{4\pi d \times 900\,000.}$$

in which K = specific inductive capacity of the insulating material, S = area in square centimeters, d = the distance between two sheets of tin or lead foil in centimeters and $\pi$ = 3.142, or, if S is expressed in sq. inches and d in inches and K = 1.7 for paraffin paper, then

$$C = \frac{2.54 \times S \times 1.7}{4\pi d \times 900\,000} = \frac{.000\,000\,38 \times S}{d}$$

The capacity of the finished condenser will only approximate the calculated result because d and K can only be approximately determined. 900 000 is a constant used to reduce it from the electrostatic unit of capacity to microfarads. It is well to use two sheets of thin paper between the sheets of lead foil, care being taken to reject any paper sheets having pin holes. Typewriter paper may be used for this purpose. It comes in boxes containing about 480 sheets, 10x9 in., costing about 45 cts. a box for the thin paper. Cheaper paper could be used. Two sheets are about .005 inches thick, but when paraffined will measure about .007. If c is to be one microfarad and d is .008 inches, then the number of square inches of lead foil required can be calculated.

$$S = \frac{.007}{.000\,000\,38} = 18420 \text{ square inches.}$$

Lead foil comes in pound packages containing 12 or 13 sheets 36x8 in. each. Each sheet may be cut into four pieces 9x8 in. and, allowing liberally for overlapping ends, there will be 7½x8 in. in each sheet. The number of sheets required will be

$$\frac{18420}{7.5x8} + 1 = 308 \text{ sheets or } \frac{308}{12x4} 6.4 \text{ lbs.}$$

say 6½ lbs. of lead foil per microfarad.

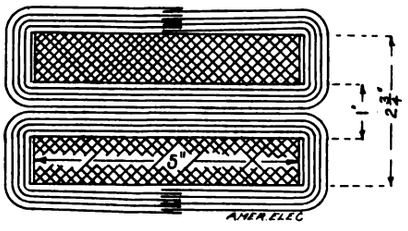

FIG. 13.

By getting paper 9 in.x9½ in., a more economical shape, one microfarad would require

$$\frac{18420}{8¼ \text{ x}8\text{x}12\text{x}4} = 5.7 \text{ lbs.}$$

Paraffin should be melted in a shallow dish large enough to allow the paper sheets to be easily dipped in it. If the paraffin is hot enough the air bubbles will

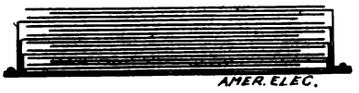

FIG. 14.

run off when the paper is removed from the bath, but care should be taken not to boil or burn the paraffin or singe the paper. The paraffin paper should be allowed to harden before laying it down.

Build up the condenser by laying down first two sheets of paper, upon this a sheet of tinfoil projecting ¾ in. over on the left, then two sheets of paper, then

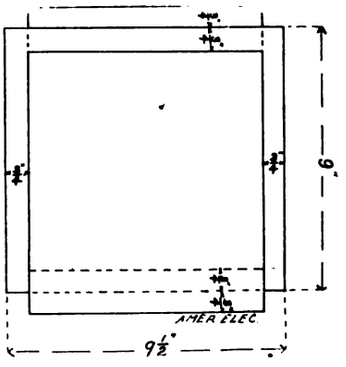

FIG. 15.

one sheet of tinfoil projecting ¾ in. over on the right. So continue to pile up all the paper and foil as shown in Figs. 14 and 15. It should then be pressed tightly together in a letter book press, placed into a shallow wooden box into which it will just fit, and the lid of which, when screwed down, will hold the sheets tight together. For terminals screw down a brass plate on the overlapping exposed ends of the lead foil. To this plate screw or solder a wire which should be brought out through a hole in the box, bushed with rubber tubing. Before screwing down the lid pour melted paraffin around the edges.

## INTERIOR WIRING.

### CONDUITS.

BY CHARLES E. KNOX.

So many changes and innovations have been made recently in conduits that it may not be inappropriate to consider, at this juncture, the various forms of electrical conduits which are used at the present time for interior wiring. Also the various rules and regulations governing their use, together with the requirements as to the covering on the wires to be used in the different forms of conduits.

All the forms of conduits used for interior wiring may be grouped under three heads:

1st—Rigid conduits with lining of insulating material.

2d—Rigid conduits without lining, but having an inner coat of enamel or similar material.

3d—Flexible conduits.

Before proceeding to consider each of these conduits separately, let us review the qualities which go to make up a good interior conduit and the rules and requirements formulated by the National Board of Fire Underwriters for the use of conduits in general.

First and foremost, a conduit for interior wiring should be fire-proof. This should always be the first consideration for any form or type of conduit. There is as a matter of fact no conduit in use today that does not fulfill this requirement. The reason for this is not hard to find, as there exists in every electric circuit for lighting or power, the elements necessary to cause a fire and every precaution should be taken to prevent the conduit from igniting and burning.

In the second place it should be moisture proof. That is to say, it should be of such material or construction as to not absorb or hold moisture and should be of such construction as would either prevent moisture from getting into the tube, or if it be possible, to rid itself of moisture condensing in, or percolating through, the tube by ventilation or by any other similar natural process.

Again it is desirable (although not essential) that the tube should be strong mechanically. It should resist nails, hard blows and should not easily be flattened by being walked upon or by having wheelbarrows run over it. In the modern fire-proof building the conduits are subject to hard usage, as they are frequently installed before the flooring is placed over them. In the days of the old unarmored paper tube and of thin brass armored conduit great damage was frequently done in this manner to the conduits and sometimes entire runs had to be replaced on account of flattened and damaged tubes.

Again, where the conduit is to be used in fire-proof buildings the armor of the conduit should resist the action of cement. The inability to withstand the action of cement on the copper was one of the weak points of the old brass armored conduit.

Again, the lining of the tube (if there

Digitized by Google

be any lining) should be flexible, so that when the pipe is bent the conduit will not crack or break.

Lastly, the tube should withstand a "short circuit" on the wires which they contain, without disrupting.

The requirements of the National Board of Fire Underwriters in regard to conduits in general are as follows: (See "National Electrical Code," Rule 25 "a" to "f.")

a. No conduit having an internal diameter of less than five-eighths of an inch shall be used. (If conduit is lined, measurement to be taken inside of lining.)

b. Must be continuous from one junction box to another or to fixtures, and the conduit tube must properly enter all fittings.

c. Must be first installed as a complete conduit system, without the conductors.

d. Must be equipped at every outlet with an approved outlet box.

e. Metal conduits, where they enter junction boxes, and at all outlets, etc., must be fitted with a capping of approved insulating material fitted so as to protect wire from abrasion.

f. Must have the metal of the conduit permanently and effectually grounded.

Also (rule 49 a), each length of conduit, whether insulated or uninsulated, must have the maker's name or initials stamped in the metal or attached thereto in a satisfactory manner, so that the inspectors can readily see the same.

With the exception of e (and possibly f, in some cases), the above rules are worthy of being strictly complied with in all cases. If a good outlet box is used, there can be no object, so far as the writer can see, of using an insulating cap with the lined conduit at outlets. With the unlined conduit it may be desirable to use it. With either kind of conduit, however, it is well to use them where the tubes enter the cut-out cabinet.

Let us now proceed to consider each of the three groups of conduits separately.

1st—Rigid conduits with lining of insulating material.

In the supplement to the National Electrical Code of 1899 (issued quarterly) containing list of electrical fittings that have been examined and approved by Underwriters' National Electric Association, there are four makes of conduit approved under this head. These four makes are as follows:

Armorite Interior Conduit Company, Pittsburgh, Pa.

Clifton Manufacturing Company, Boston.

Consolidated Insulated Tube Company, Boston.

Sprague Electric Company, New York.

The Armorite interior conduit consists of an iron pipe lined with wood. The lining is made from live kiln dried bass wood cut with tongue and groove in two semi-cylindrical sections; thoroughly treated under pressure with a product of petroleum penetrating every pore and destroying the active properties of the wood excluding gases and moisture. The two sections are then placed together (over a mandrel) forming a complete tube, and forced into the steel armor. The wood can be cut any thickness, but is ordinarily cut, unless otherwise specified, 1/16 inch thick. The object in putting it in the tube in two sections is that it can be easily bent to any angle without affecting the pipe or wood lining. (Quoted from circular issued by Safety Armorite Co.) The objection which has been raised against this tube is that the wood lining is apt to crack in bending the tube.

The tube made by the Clifton Manufacturing consists of a standard iron pipe lined with vulcanized rubber.

The conduit made by the Consolidated Insulated Tube Company is very similar in material and construction to the Clifton conduit. Neither of these conduits have been used to any great extent. In fact, so far as the writer knows, their use has been almost entirely limited to the neighborhood of Boston. For this reason little can here be said of their practical merits or demerits.

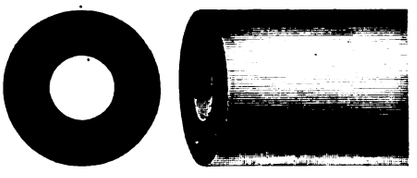

FIG. 1.—CONDUIT WITH HEAVY IRON WALL AND HEAVY INSULATING LINING.

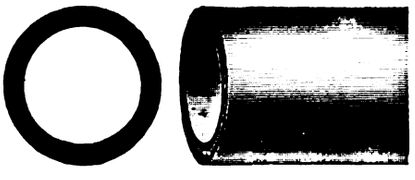

FIG. 2.—CONDUIT WITH THIN IRON WALL AND THIN INSULATING LINING.

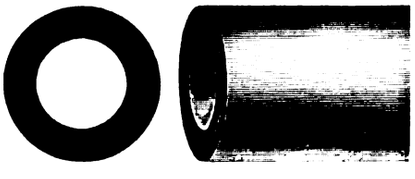

FIG. 3.—CONDUIT WITH HEAVY IRON WALL AND THIN INSULATING LINING.

The iron armored conduit made by the Sprague Electric Co. (formerly the Interior Conduit & Insulation Co.) consists of an iron lined with a tube of paper treated with an asphaltic compound. This tube is cemented or fastened to the inside of the iron pipe so as to form an integral part of the same. Cuts 1, 2 and 3 show the various evolutionary forms of this conduit. Figure 1 shows an iron pipe of standard thickness and diameter of ordinary gas pipe, with a thick insulating lining. This conduit was in use about three years ago. About two years ago the thickness of both the iron pipe and the paper lining were reduced and the conduit shown in Fig. 2 was the result. This was approved by the Board of Fire Underwriters and has been in use up to the present time. The Board of Fire Underwriters has recently passed a rule (see National Electric Code, Rule 49 b) that the metal covering of all conduits must be equal in strength and thickness to the standard gas pipe of the corresponding size. The insulating lining may, however, be the same as that used on the conduit shown in Fig. 2. This heavy armored conduit is shown in Fig. 3. This rule goes into effect on all contracts closed after July 1, 1899.

The new rules governing the use of these lined metal conduits with insulating lining, and which go into effect on all contracts signed after July 1, 1899, are as follows:

49. Interior Conduits. Metal Conduits with Lining of Insulating Material.

b. The metal covering or pipe must be equal in strength to the ordinary commercial forms of gas pipe of the same size, and its thickness must be not less than that of standard gas pipe, as shown by the following table:

| Size. Inches. | Thickness of Wall—Inches. | Size. Inches. | Thickness of Wall—Inches. |
|---|---|---|---|
| ⅜ | .109 | 1¼ | .140 |
| ½ | .111 | 1½ | .145 |
| ¾ | .113 | 2 | .154 |
| 1 | .134 | .... | .... |

An allowance of two-one-hundredths of an inch for variation in manufacturing and loss of thickness by cleaning will be permitted.

c. Must not be seriously affected externally by burning out a wire inside the tube when the iron pipe is connected to one side of the circuit.

d. Must have the insulating lining firmly secured to the pipe.

e. The insulating lining must not crack or break when a length of the conduit is uniformly bent at temperature of 212 degrees Fahrenheit to an angle of ninety degrees, with a curve having a radius of 15 inches, for pipes of one inch and less, and 15 times the diameter of pipe for larger pipes.

f. The insulating lining must not soften injuriously at a temperature below 212 degrees Fahrenheit and must leave water in which it is boiled practically neutral.

g. The insulating lining must be at least one-thirty-second of an inch in thickness, and the materials of which it is composed must be of such a nature as will not have a deteriorating effect on the insulation of the conductor, and be sufficiently tough and tenacious to withstand the abrasion test of drawing long lengths of conductors in and out of same.

h. The insulating lining must not be mechanically weak after three days' submersion in water, and when removed from the pipe entire, must not absorb more than ten per cent of its weight of water during 100 hours of submersion.

i. All elbows or bends must be so made that the conduit or lining of same will

Digitized by Google

not be injured. The radius of the curve of the inner edge of any elbow not to be less than three and one-half inches. Must have not more than the equivalent of four quarter bends from outlet to outlet, the bends at the outlets not being counted.

We will now proceed to consider the next class of approved conduits:

2d. Rigid conduits without lining, but having an inner coat of enamel or similar compound.

The various makes of unlined enameled conduits approved in the "List of Electrical Fittings" issued by the Underwriters National Association are as follows:

Armorduct, Armorite Interior Conduit, Company, Pittsburgh, Pa.

Electroduct, Boston Electroduct Company, Beaver Falls, Pa.

"Loricated Pipe," Safety Conduit Company, Rankin Station, Pa.

As far as the writer can ascertain, these conduits are very similar and differ chiefly in the color of the enamel lining—not a very essential point. The iron tubes are smoothed and cleaned before being coated with the enamel and present a very smooth uniform interior after being enameled. It is claimed that these tubes can be bent without cracking the enamel, which is true if ordinary care is taken in making the bends. This conduit has the advantage over the lined conduit of being smaller in external diameter with the same inside diameter of the lined conduit. The latter conduit has the advantage over the unlined pipe, of being better able, on account of the lining, to resist the rupture of the pipe, which is apt to be caused sometimes by "short circuits" occuring on the branch circuits carried within the conduit. Fig. 4 shows an unlined enameled conduit of this class.

The rules of the National Board of Fire Underwriters governing the use of unlined metal conduits are as follows:

UNINSULATED METAL CONDUITS.

j. Plain iron or steel pipes of equal thickness, and strengths specified for lined conduits in No. 496, may be used as conduits, provided their interior surfaces are smooth and free from burs; pipe to be galvanized, or the interior surfaces coated or enameled to prevent oxidization with some substance which will not soften so as to become sticky and prevent wire from being withdrawn from the pipe.

k. All elbows must be made for the purpose, and not bent from lengths of pipe. The radius of the curve of the inner edge of any elbow not to be less than three and one-half inches. Must have not more than the equivalent of four quarter bends from outlet to outlet, the bends at the outlets not being counted.

3d. Flexible Conduits.

Under this head there are two conduits which are approved in the Supplement to the National Code. The first of these is the Circular Loom Conduit, made by the American Circular Loom Co., Chelsea, Mass.

The Circular Loom tube is constructed of a spiral of insulating fibre wound with a heavy Para rubber friction tape; over which is a continuous woven jacket of cotton similar to that used in the ordinary garden hose. The whole tube is then saturated with an insulating compound. After this the tube is dipped in,

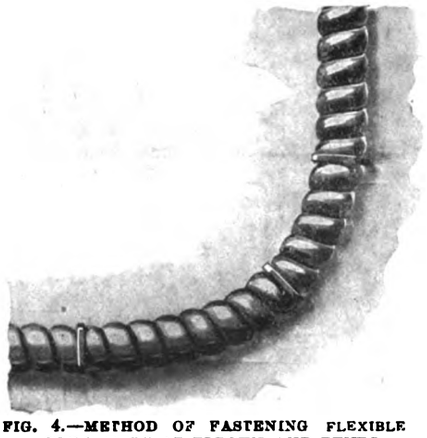

FIG. 4.—METHOD OF FASTENING FLEXIBLE STEEL TUBE AT ELBOWS AND BENDS.

or run through powdered mica, which makes it less likely to take fire.

The advantages claimed for this tube are that it is "flexible, water proof, it requires no joints or elbows, will not readily ignite, wires will not stick in it and it can be furnished in any length." As a matter of fact, however, it is not waterproof, does not resist the action of cement and wet plaster, and obviously it is not strong mechanically. For certain purposes, however, it is very useful, as for example in finished buildings, back of switchboards and other similar places. The rules of the Fire Underwriters practically limit its use to old or finished buildings of frame construction where it may be fished in between the beams and plaster and where it is not liable to the action of wet plaster or cement, or to injury from nails, etc.

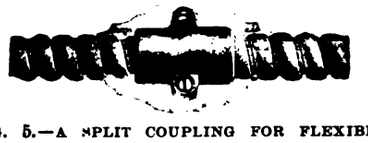

FIG. 5.—A SPLIT COUPLING FOR FLEXIBLE STEEL TUBING.

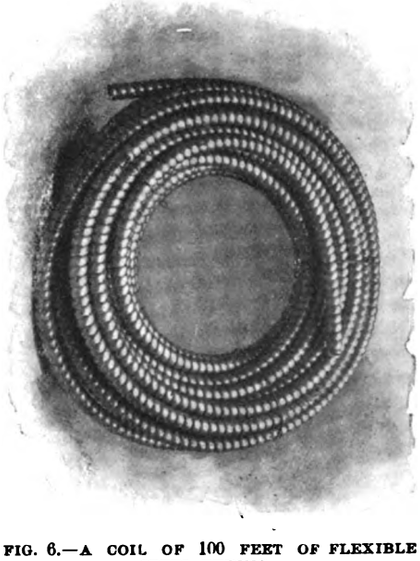

FIG. 6.—A COIL OF 100 FEET OF FLEXIBLE STEEL TUBING.

The Greenfield flexible steel conduit, which is approved by the National Board of Fire Underwriters is governed by the same rules as the unlined metal conduits. It is a new conduit introduced by the Sprague Electric Co. within the last six months. The conduit is described as a "conduit composed of convex and concave metal strips. These strips are wound spirally upon each other in such a manner as to interlock their concave surfaces, and present their convex surfaces, both exterior and interior, thereby securing a smooth and comparatively frictionless surface inside and out."

The advantages claimed for this tube are continuity, flexibility, ventilation and mechanical strength.

A continuous tube has a great advantage over a tube which comes in short lengths, as it avoids joints, couplings, etc., and can therefore be much more quickly installed. This tube comes in coils of 100 feet. Fig. 6 shows a coil of 100 feet.

Flexibility in a conduit is not always an advantage. In many cases it is very desirable, but sometimes it is a decided disadvantage. Of course it dispenses with elbows, as a bend of almost any radius can be made with this tube, with no other tools than the hands. But, mark this carefully, the greatest trouble may be caused by this flexibility, unless proper care be taken in installing this tube. It is of the utmost importance that each tube be securely fastened in at least two, and preferably three, points at the elbow. If this precaution is neglected, it will make it very difficult if not impossible to pull the wire through the conduit, because the tube will buckle and assume such shapes as to cause it to effectually bind or grasp the conductor, which is being pulled through the conduit. Fig. 4 shows the proper method of fastening this conduit at elbows and bends.

There is no doubt about this tube being a ventilated tube. If smoke is blown through one end of a short length of this pipe it will all come out through the fissures between the spirals before it reaches the other end. In many places this would be an advantage, as, for example, in exposed work, or in places where it would be concealed in cement or plaster. But it is very questionable that it is an advantage under tiled floors or in plastered walls where water (and other things beside) might get in the pipe, and where the ventilation would be reduced to its lowest limits. In such cases as these there is no doubt that a solid pipe with leaded joints would be much dryer and better.

The tube is quite strong mechanically, although not absolutely nail proof.

Fig. 5 shows a coupling for this conduit, and the method of using it with the conduit.

This new conduit will of course find its proper place in time. That there is a place for it there is no question, as for some particular purposes it is superior to any of the other conduits.

## VALVE REPAIR TOOLS.

It has been stated in these columns that solid seat, metal to metal valves are the best while they last, but that they are very easy to damage by too much screwing down when closed. It is again in order to state that solid seat valves should have the disc merely touched down upon the seat when closed. Pressure applied after this only does damage and does not close the valve any tighter. The same is true with the soft packing valves, but they are not injured quite as much by the hard screwing process as are the solid seat valves. The principal cause of leakage in this class of valves is in the cutting or abrasion of the seat or disc, through being screwed against some hard substance. Perhaps an iron chip from a pipe thread is one of the most prolific causes of injury to solid seat valves. The presence of sand, boiler scale, or other earthly matter also spoils many seats and discs. Sometimes the partial closing of a valve against some soft substance, like a chip or a bit of string, allows steam or water to leak through and cause injury to seat or disc through cutting caused by the "sand-blast" action of water or other foreign matter which is carried along by the steam.

In all cases where solid seat valves are used provision should be made for the regrinding of the seat and disc or for the renewal of the closing surfaces by milling or filing the damaged surfaces. To this end a number of machines or devices have been perfected and placed upon the market, and several of these are illustrated herewith. In previous articles several types of "regrinding" valves have been illustrated and described. These are ordinary solid seat valves, made with solid discs, also, and so constructed that by means of pins or clamps the valve stem may be relieved from its screw and locked to the disc and the grinding effect-

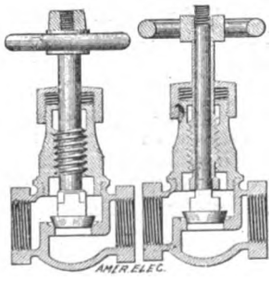

FIG. 1.—SPAULDING VALVE GRINDING DEVICE.

ed by rotary motion applied with pressure direct to the valve stem, the hand wheel being either grasped directly in the hand or caught by the chuck of a bitstock or a breast drill. In this kind of valve reseating the grinding is effected either by the use of grindstone dust, or, what is better, by the use of pulverized glass or silica sand. Emery is not good for this purpose, for, while it cuts away the metal very fast, it has an ugly habit of becoming so imbedded therein that it cannot be removed by any ordinary means, and continues to cut and grind while the valve is in use, thereby defeating the very purpose for which the cutting material was applied to the seating surfaces.

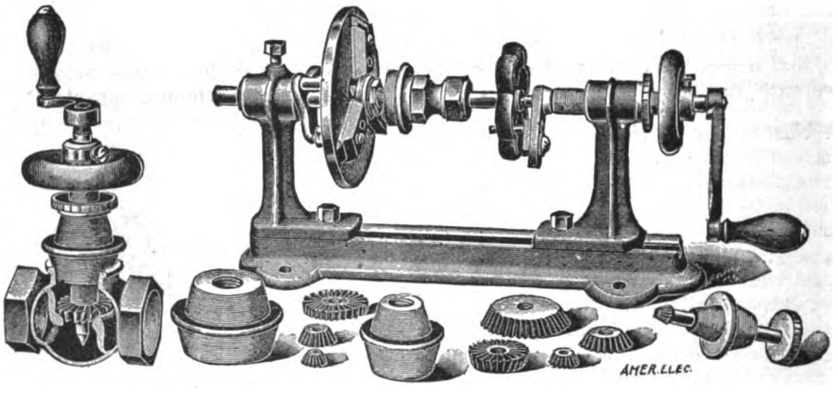

FIG. 4.—STANDARD VALVE RESEATING MACHINE.

Fig. 1 shows a valve specially constructed for this purpose, and as shown by the illustration the stem is independent of the screw, being placed inside a sleeve which carries the latter, and

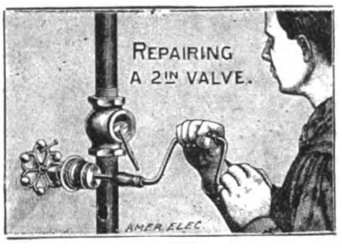

FIG. 2.—DRAPER'S VALVE FACING TOOL.

locked rigidly thereto by means of a cap nut at the hand wheel end and a shoulder collar near the disc. This valve was invented by A. R. Spaulding, Clinton, Maine, and possesses several points of

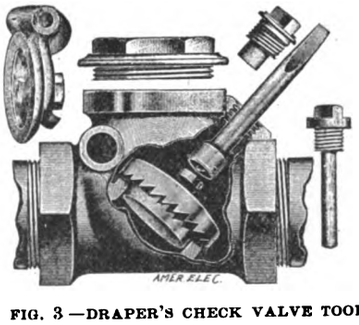

FIG. 3.—DRAPER'S CHECK VALVE TOOLS.

excellence. By attaching the valve stem to a bitstock, by means of a short plug hole in a tapped chuck, the disc, which can be locked to the valve stem, is rotated in the usual manner and the grinding prosecuted at any speed desired. For this purpose the hand wheel may be turned until the disc bears with any required pressure upon the seat. There is, then, no need of applying pressure upon the bitstock by the operation, but the hand wheel may be used to feed the disc down as fast as the disc or seat is ground away, or accordingly as the abrading material becomes reduced in cutting power.

Several types of valve repair outfits are made to be used with an ordinary bitstock, and the one shown by Fig. 2 may be taken as a fair representative of this class. It is simplicity itself, and comprises two bitstock tools for each size of valve. The engraving shows the whole operation so plainly that little description is necessary, except to state that the disc centers itself, no matter at what angle (within limits, of course,) the bitstock may be held. In cutting down the seat the file disc is so guided by the seat that it is quite easy to mill the surface thereof to a level condition. It is, however, possible to cant the tool and mill one side of the seat lower than the other, but this may always be avoided by proper care in doing the work. Some of this class of tools are provided with a taper threaded plug through which the cutting tool stem passes, thus allowing the same plug to fit several sizes of bonnet openings in different makes of valves. This tool is manufactured by T. Draper, Port Huron, Michigan. Another form of this tool, which belongs to the "valve-file" class, is shown by Fig. 3, and is used for repairing swing check valves. In this engraving both the application of the tool is shown, also the method of getting it into place, the reamer disc being separable from the stem, the parts being put in place from different directions. Here the seat forms the guide for the cutting disc, the joint in the stem serving as a ball and socket joint to render the disc independent of the movements of the stem and its connected bitstock.

It is easy to divide valve repairing tools into two general classes, in one of which the circular or segmental file is used; the other using a lathe tool for obtaining a surface. Either of these classes may be subdivided according to construction into several types, according to the method of application of the cutting tool, or to the manner of holding the work. In some types of the first class the so-called files, or reamers, have been developed into high grade milling cutters. This is particularly the case

Digitized by Google

with the tool shown in Fig. 4, which represents the Standard Valve Reseating Machine, as originally manufactured by F. S. Dangerfield, Auburn, New York.

The taper bushing mentioned above is used in this machine, and several sizes are shown in the engraving thereof. Cutters are furnished, both flat and taper. There is a hand feed arrangement for small valves, and a large, positive feed device for use with the larger sizes of valves.

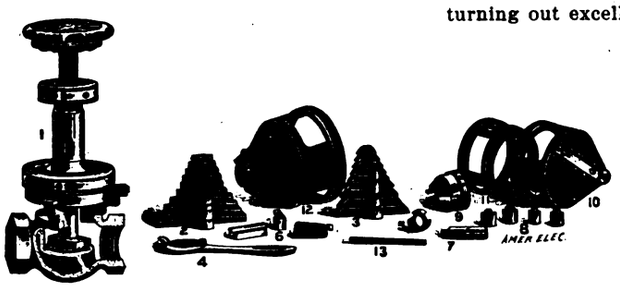

FIG. 5.—MORSE VALVE RESEATING MACHINE.

The hand wheel serves to feed the cutting tool, and the crank applies power for obtaining the necessary rotary movement. For regrinding the disc the mechanism above described is placed in a standard, which, in turn, is mounted on a small iron bedplate, the disc cutting arrangement is built up in an adjustable manner upon a face plate, as shown in the engraving. This plate carries a yielding dead center which serves to center the valve stem, then recedes before the valve as the latter is pushed up to the cutter by the feed screw. An opening in the face plate allows the wings of check valves to project.

Some of the "file-cutter" valve repair machines use only a narrow section of a cutting disc, virtually becoming machines of the class that use a lathe tool to do the cutting. But to reduce the number of types of machines as much as possible, this type will be here described as belonging to the "filing" or "milling" valve tools.

Fig. 5 represents what is known among engineers as the "Morse and Dexter" machine. It is put on the market by the Leavitt Machine Company, Orange, Mass., and is made in several forms, as shown by the succeeding engravings. As shown by Fig. 5, there is a tool which may be centered in the bonnet opening by means of a three-jawed internal chuck, and the seat ground by a positive feed of the milling tool, as already described.

Both straight and taper tools are provided for milling off flat and countersunk seats, and a number of small mills are supplied for the smaller sizes of valves. For turning up bevel discs the conical "pencil-sharpeners" are provided, and there is also a small chuck which is found useful in handling little valves. This form of valve machine is capable of turning out excellent seat surfaces owing to the great rigidity of the mechanism which attaches it to the valve, which, by the way, need not be removed from the piping when reseating is necessary. Three steps are provided on the internal jaws of the chuck, which are threaded to suit the bonnet openings. To ensure still smoother carrying of the stem, the sleeve in which it runs is split and fitted with a taper thread and nut wherewith all the lost motion is taken up and the cutting tool made to run without even the sign of a chatter. The conical reamer shells are threaded to fit the bonnet of a valve. The disc is then fed down by the hand wheel and screw, and rotated therein until the seating edge is brought to the required degree of perfection.

Another set, the Morse and Dexter machine, by the same maker as above, is shown by Fig. 6. In this machine the conical cutter is dispensed with and a small screw-driven slide nut carries a tool and is set at the proper angle to cut down the edge of a disc.

A horizontal machine, with a frame made of round steel, carries the disc turning device, and can be adjusted to almost any size of disc. Two internal chucks come with one of these machines. The slide rest tool, cutting at but a single point, reduces the irregularity of the disc without the possibility of springing the stem under heavy pressure, thereby turning out the best possible results.

Bushings for attaching different sized valve discs are also provided, as shown in the illustration.

Still another "Morse" outfit is prepared by the Leavitt Company, as shown by Fig. 7. This will dress both flat and bevel seats and discs from one-fourth to six inches in diameter, and the "universal cut" principle is used. The narrow parallel segment cutters, with cutting teeth at both ends, are employed, as described elsewhere in this article.

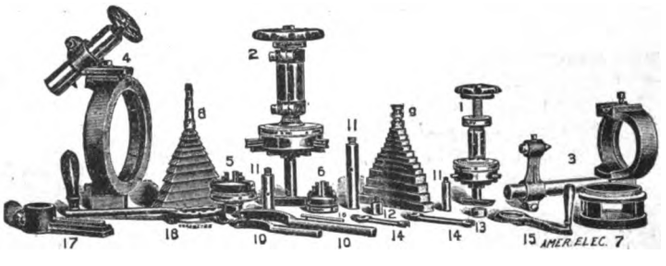

FIG. 6.—MORSE AND DEXTER VALVE MACHINE.

In this tool the bonnet, with contained stem, is screwed into a circular frame which carries three bevel cutters arranged like the jaws of a chuck, and by revolving the chuck ring by means of a spanner, thereby enables any size of disc to be turned up, a set of bushings being supplied for the very smallest bonnets.

A very simple, yet efficient form of the Dexter tool is shown by Fig. 8. In this the discs are chucked in the same tool which is used for turning up the seats. A circular frame carries the cutter, said frame being screwed into the vise when in use for cutting discs. When a flat disc is to be recut, the holder, 5, is put on. When seats are to be cut the tool is removed from the circular frame, a cutter, 3 or 4, is put in place of the disc and the device is fastened into the bonnet opening by means of the internal chuck already described.

A form of chuck is shown at 10 for use in attaching check discs and some other peculiar forms of valve discs.

By a recent improvement in this form of cutter greater stability has been given to the disc when in process of being cut, particularly when some of the "loose" discs are used.

## A SIMPLE COAL HANDLING EQUIPMENT.

BY JAMES F. HOBART.

A coal handling machine which is in operation on South Street, New York City, a short distance north of Fulton Ferry, seems to contain several points of considerable value to power station managers. This device is a self-contained power hoist, yet it is portable and easily managed. One man can run the hoisting engine and attend to the crane when a boat is nearly empty. Then it is quicker to shovel up by hand the few lumps of coal that remain, although they can be almost all picked up by the big shovel if the operator is satisfied with the few lumps of coal at a time which chance to be immediately under the shovel when it strikes the bottom planking.

Fig. 2 shows the shovel filled with coal. It has closed and is ready to be hoisted. An old sail is shown in the foreground which is stretched between the boat hatchway and the dock, to catch any pieces of coal which may chance to fall out of the shovel.

Fig. 3 shows the whole machine, the hoisting engine being enclosed in a house which is mounted on wheels, although in this case it has been raised considerably by blocking under the wheels. This, however, is unnecessary if the pile of screenings be kept well cleaned away, so that a wagon body can go under the screen without trouble. The shovel is shown filled and in the act of being hoisted, and when it reaches the boom, or yard, the latter swings up to a vertical position, being pivoted at the bottom for that purpose.

The action of the boom is thus entirely automatic. When fully raised it inclines a very little from the vertical, just enough in fact so that it will be sure to fall when the hoisting chains are slacked off on the drum. That portion of the truck frame which lies forward of the boiler is planked up in the form of a hopper, which will hold about eight or ten tons of coal. At the bottom of the hopper a sliding door is arranged through which coal may be drawn directly into a cart, or into an elevator or conveyor, as may be necessary. When used by a coal dealer and several kinds of coal are to be handled, it is necessary to have several chutes, as shown on the ground in the foreground. These chutes are detachable and are readily removed. The bottom of the chute is covered with wire netting, different sizes of mesh being used to screen out the fine coal and dirt, a pile of which is shown on the ground.

Fig. 4 shows the completion of handling a shovel full of coal, the load having

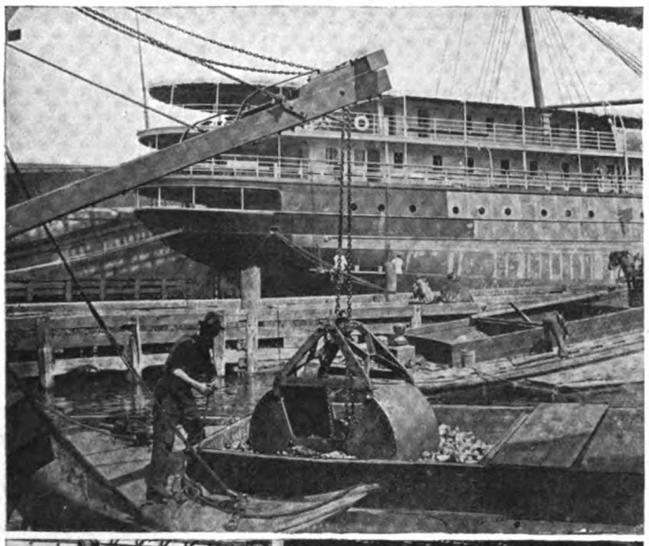

FIG. 1.—FILLING THE SHOVEL.

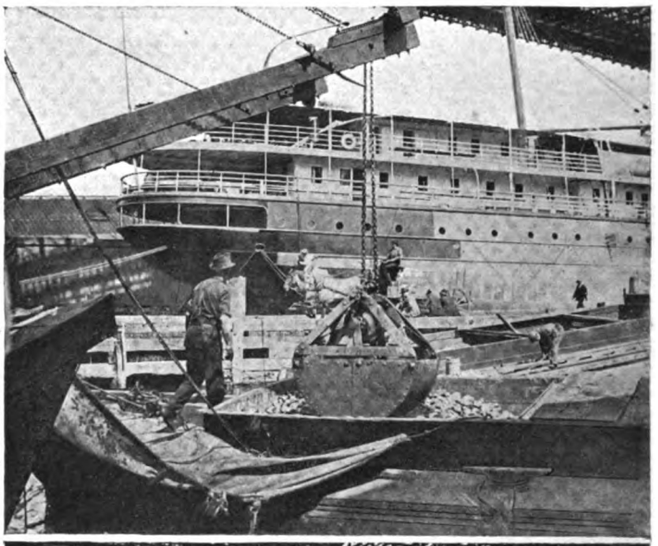

FIG. 2.—SHOVEL SELF-FILLED.

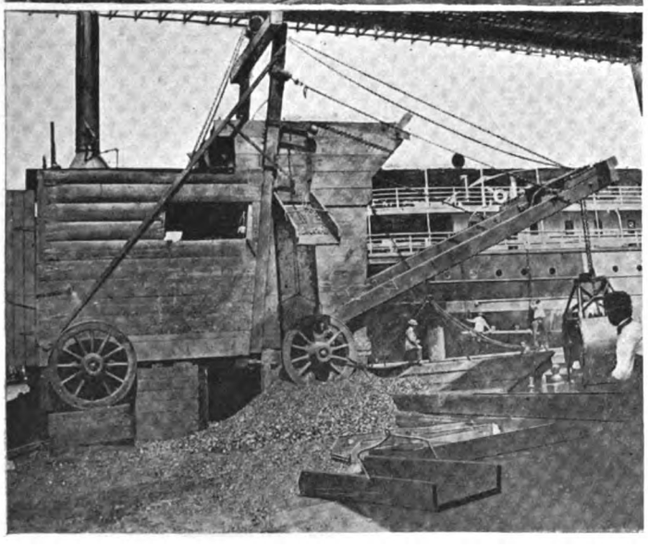

FIG. 3.—HOISTING A SHOVEL FULL.

FIG. 4.—DUMPING SHOVEL INTO CART.

manipulation, which is almost automatic in its action, there being but two chains to pull, the boom or yard taking care of itself. But one other man besides the engineer is necessary, and he attends to placing the shovel in the canal boat, seeing that the shovel, which is self-loading, and is shown in the act of filling in Fig. 1, does not get cramped against the side of the canal boat or jammed against a vessel's bulkhead or side.

There is nothing novel about the shovel. It is of the self-filling variety and nothing need be done to it except

Digitized by Google

been dropped into the chute, and being shown in the engraving in the act of running through the screen chute into a cart, to be teamed away.

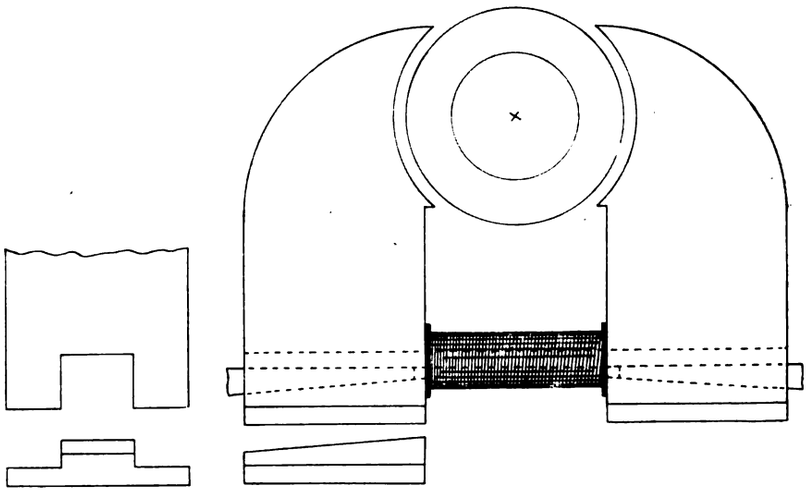
Once the bucket and boom have been hoisted to the end of their travel, it is only necessary to let go the loading chain and the shovel spills its contents without further manipulation. There is a cart loading chute on both sides of the hopper, and the engraving shows another team on that side also. A complete cycle of operations can be gone through with in about 45 seconds, although 60 or even more can be spent to advantage when there is no great occasion for the highest working capacity.

As stated, this rig, or a modification of it, would prove of considerable value in central station or power house work, and a machine of this kind could be advantageously built upon a car body and fitted with a pair of motors in place of the steam engine here employed. Not only would this arrangement be valuable for handling coal, but it would do great work with ashes, or in ordinary excavating, between or alongside street railway tracks. In such cases the earth could be loaded directly into carts or chuted into cars placed upon the other track alongside. If desired, the boom could be fitted to swing, thereby uniting the virtues of a coal hoisting machine, a steam shovel and a dredging machine.

## A PERMEAMETER FOR SHOP SERVICE.

BY CECIL P. POOLE.

The accompanying sketch shows roughly a design for a permeability testing machine which was built by the writer several years ago and was found to be thoroughly satisfactory under conditions of shop practice where the more delicate appliances commonly used for testing iron were absolutely unreliable because of disturbing influence. The machine is, broadly, a dynamo having for its magnet core the piece of iron to be tested; the pole-pieces and armature core are relatively massive, and the winding, of course, is calculated to give convenient ratios between exciting current and magnetic flux.



The pole-pieces were 5 inches square. with the edges rounded off to ½-inch radius; the cross-section was maintained unchanged up to the air-gap. The bottom of each pole-piece or yoke was slotted, the slot being 2 inches wide and 1½ inches deep; a foot-piece was provided for each yoke, having a central rib fitting snugly in the slot and tapering from ⅜-inch high at one end to ¾-inch at the other, as shown at the left of the sketch, giving the slot in the yoke an inclined floor. The yokes were bolted to a heavy wooden base, the bolts passing through the foot-pieces just described, so as to make their position relative to the yokes permanent.

The test piece was 2 inches wide, fitting within the yoke slots snugly; 27/64-inch thick and 15 inches long. The distance between the sides of the yokes was 5 inches, and the exciting coil was 4 15/16 inches long over the heads, so as to be easily removable. The test piece was clamped firmly against the surfaces of the yokes forming the upper wall of the slots by means of wedges driven in at each end, as indicated by dotted lines; these did not need to be driven hard home by any means, a couple of light taps with a machinst's hammer, after being pushed in as far as possible by hand, being sufficient.

The armature core was 6 inches in diameter and the radial depth was 1¼ inches; the net axial length was 4 inches, giving a cross-section of 10 square inches. Fibre end rings were used to fill out the length of armature necessary to put the clamping rings (of composition metal) beyond the reach of the field, and the armature was wound, ring fashion, with three layers of No. 13 wire, 375 turns per layer, giving a total of 1125 turns. The direct-reading. An ordinary Weston voltmeter was used, having a range of 150 volts, but it would have been more convenient, obviously, to use an instrument of lower range with a wider scale.

The armature was driven by a small plating machine used as a motor and supplied from two storage cells, a liquid rheostat being used in series with the armature for regulation as the e. m. f. of the cells became lower; the speed was carefully taken four or five times for each test, with a portable tachometer, and the value ascertained originally to be the proper one was, of course, secured before testing.

The machine was calibrated, so to speak, by using a "standard" piece of wrought iron, the permeability curve of which had been previously determined by several ballistic galvanometer tests, and, although this piece was religiously preserved and the machine frequently tested with it, it was never found to vary from the results originally obtained.

PARTS OF A PERMEAMETER.

length of each air gap was ¼ inch; the core was smooth.

The exciting coil was 4⅝ inches long, net, and wound on a bobbin of very thin brass, the interior of which measured 2 1/16 inches by 15/32 inch, the clearance being just enough to permit it to slip over the test piece readily. The coil consisted of No. 12 wire wound in two layers of 50 turns each, so that each ampere of exciting current gave 100 ampere-turns. This coil was excited from a storage cell capable of a discharge rate of 30 amperes, less than 2 volts being required at the highest magnetic densities. The magnetic circuit (beyond the test piece) required 50 ampere turns per 1000 gausses density in the test piece, so that it was a simple matter to deduct from the total exciting force (in ampere-turns) that portion used elsewhere than in the specimen. The speed of the armature was 1017 revolutions per minute, at which speed a voltmeter connected to the brushes indicated 1 volt for each 1000 gausses in the test piece, making the apparatus practically

The reason for using a test piece of rectangular cross-section and lapping the ends was that the machine could be used for testing sheet iron, the sheet being cut into strips of the proper length and width and enough of them bundled together to make the requisite thickness. For testing solid metal only it would have been more desirable to make the test bar round and only 5 inches long (or 4 31/32, to slip easily between the yokes). Firm contact at the ends could have been secured by means of a tightly fitting plug, screwed through one yoke so as to butt against the end of the test piece. Then the exciting force could be expressed in ampere-turns per inch of length, whereas with the rectangular test piece the permeability curve had to be plotted first, the abcissae being in ampere-turns instead of in terms of H. It was intended originally to thus build the machine, but the more universal character obtained by making the test piece rectangular outweighed the greater convenience incidental to the other construction.

## A SMALL STORAGE BATTERY PLANT FOR DOCTORS.

BY F. E. WOODFORD.

As the use of storage batteries for large power houses and sub-stations is continually increasing, their adaptibility for almost every kind of work is becoming more and more realized. With their increased demand, a corresponding increase in their quality has been the result, until at present, with their high efficiency and the flexibility with which they can be operated, their use as small auxiliaries of electric power has gone far past the experimental stage. But while portable storage batteries for the use of physicians have been on the market for a long time, it is only lately that doctors are having complete storage battery plants installed in conection with their offices to operate such devices as may there be used. It is not every locality or condition that will warrant its use, but in a great many cases, as with the one in question, it will prove very satisfactory and convenient. As nearly every case has its peculiar requirements, which are different in detail, I will not try to describe such an installation in a general way, but take up the details of an individual case.

In small towns, where the central lighting plant is run only at night, and in some places where this is even limited to part of the night, the physician who wishes to keep up with the times and whose success depends partly on the use of modern methods and appliances, is handicapped in a great degree. If he has an examination of the ear, throat or nose to make, he must use a kerosene lamp and intensifyer or make an appointment for evening, in order to have the benefit of the electrical appliances for such purposes. Delicate operations of the throat and nose can only be performed to advantage in the evening in such places. He has to use a battery which is expensive and cumbersome to heat his cautery knives, and is compelled to do many things by old methods, which, if electricity were available at any time during the day, could be accomplished in a much more successful manner. Nor is this the limit of his troubles. If the door bell rings and he is called at 2 o'clock in the morning, he arises to find he cannot turn on a light or that the light is unusually dazzling from an extremely high voltage, the outcome of a nap on the part of the attendant at the lighting station.

In some towns the lighting plant is shut down at midnight or 2 o'clock every morning. Such is the case with the physician who has made use of the storage battery plant under consideration. His house and office are supplied with electricity from dark until 2 o'clock A. M., a time which it might almost be said in his profession he needed it least. After making a thorough canvas of the appliances he wished to operate and the results he wished to obtain, it was decided that a small storage battery plant for this particular case was the most desirable.

Very good lamps can be obtained on the market that will give from sixteen to twenty candle-power at 30 to 38 volts. As these lamps, which are placed in the office, sleeping apartment and on the porch, are the appliances requiring the highest voltage, this determined the number of cells required. Sixteen cells were accordingly selected and arranged to be connected in series direct to these lamps when otherwise not in use.

As the heating of the cautery instruments requires the greatest amount of current in the list of physicians' instruments, it is the current used here that determined the size of each cell. The size of each cell is such that eight of them will heat the heaviest cautery knife, leaving the other eight to operate such instruments as might be in use at the same time. Each cell is capable of discharging eight amperes, consequently this battery of eight cells connected in multiple series, two in each series, will discharge 32 amperes at four volts, and for a short period of time still more current without injury.

The connections of the apparatus are shown in Fig. 1. With the switches open, as shown, the battery is connected direct to the lamps in office, bedrooms and on the porch. Everything in connection with the battery and medical apparatus is operated from the cabinet switchboard, which is placed in the office and as near to the batteries as was possible, to save wiring. The battery is charged by closing the switch at the top of the figure, which connects it through the resistance, R, to the 110-volt lighting circuit. The resistance coil, R, is made to carry the same amperage as one of the lamps, to prevent the lamp from burning out should it be turned on during the time of charging. In case two or more lamps are turned on at such a time, the battery will discharge into the line, thus keeping them to their full brilliancy. When the switch is closed to charge the batteries, it also cuts off all the medical apparatus at the switchboard, thus preventing its being damaged by the 110-volt current.

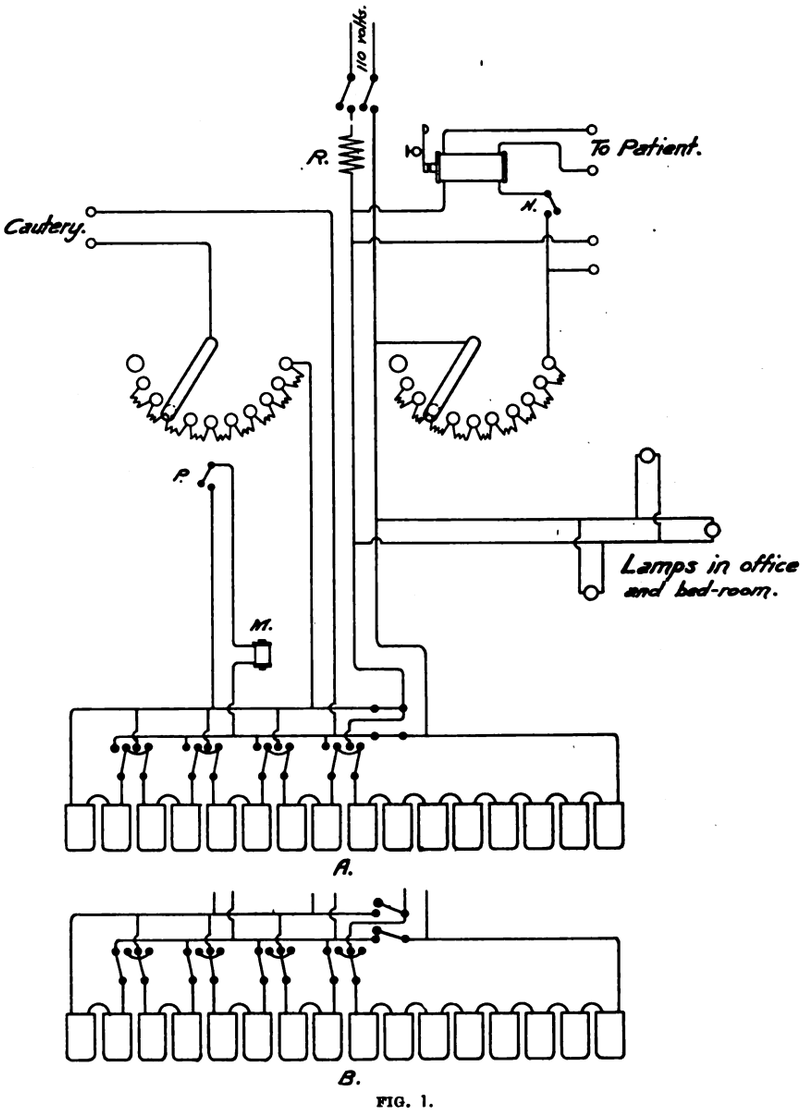

FIG. 1.

The cell being appreciably large for the small amount of current it has to furnish for the lamps, has its advantage in this direction, as well as for use with other

Digitized by Google

appliances, as it is discharging below its normal rate, which lengthens the life of the cell, and its charging is consequently less frequent. And while its size must be such as will meet the demands upon it by the cautery instruments, the current thus used is for such a short period of time that this discharge is ineffective upon its capacity. It has, therefore, been found that while the size of these cells is barely sufficient to meet their heaviest requirements, their use in the doctor's office is very successful and practical.

When the instruments connected to the switchboard are in use the battery is placed in connection, as shown at B, Fig. 1. The eight cells on the left supply current for the cautery knife alone. The cautery terminals, together with its rheostat, are shown on the left. The rheostat has 32 steps graduated to control the current from zero to five volts, making it possible for a variety of instruments to be heated from these terminals.

The eight cells on the right are left in

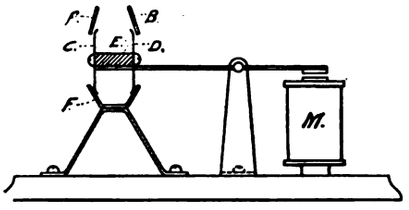

FIG. 2.

series, as shown, their current being conducted through the rheostat shown on the right to the lower pair of terminals. From these terminals can be operated a physicians' mouth lamp of one-half candle-power, also a head lamp of fourteen candle-power, and other lamps of the miniature type used in examinations and operations. This rheostat has a wide range of resistance and is also adapted to graduate the pressure of the current delivered to the induction coil from zero to sixteen volts. This induction coil is shown above and to the right in the figure. The secondary leads are conducted to the patient through the upper pair of terminals. These instruments are always operated from the eight cells to the right, and when the battery is connected, as shown at B. Their operation is, therefore, never affected by the cautery current.

The changing of the battery connections from A to B is accomplished with the apparatus shown in Fig. 2. A and B are sections of the conductors whose terminals lead up to the cautery side of the switchboard. Immediately under these copper strips, which form the main conductors, are five pairs of brass springs, C and D, screwed to the fibre strip, E. These brass springs are connected to the terminals of each series of two cells and each forms the arm of a switch. By their own weight they make a contact with the copper strips, F, which are four in number, thus connecting the whole battery in series. By closing the switch, P (Fig. 1), the magnet, M, is supplied with current at 32 volts. The magnet consequently gives a strong pull, raising the springs, C and D, which press against the conductors, A and B, thus putting the battery in the connection shown at B, Fig. 1. The magnet of the apparatus is now supplied with current at four volts, which is sufficient to hold the springs in a good contact with the conductors until the switch, P, is opened, when they will be released by the magnet and again drop, putting the battery in series. The fifth pair of springs, C and D, by this same action throw the battery into the two sections of eight cells each.

## Letters on Practical Subjects

### The Corrosion of the Leading-In Wires of Incandescent Lamps.

*To the Editor of American Electrician:*

Sir—A short time ago I installed a small electric light plant in a plating shop to the entire satisfaction of the owner, but lately the incandescent lamps gave trouble. Frequently one or two lamps would go out and not one of the filaments was broken. I was finally called in to inspect the plant.

After careful tests and finding all fixtures and wiring O. K., I naturally turned to the lamps, and although the filaments were intact, every lamp was open. Upon smashing one of the lamps I found that considerable moisture and fumes from the plating baths had gathered in the hollow base of the lamp and had partly filled the inner tube of the lamp just above the seal of the platinum wires.

This of course formed an excellent plating bath on a small scale and electrolysis soon ate the positive wire clean through. I did not anticipate that so much acid could be deposited in the base of a lamp, but this shows the importance of selecting a lamp with a solid base wherever fumes are present. I would also suggest that the plaster in the base be thoroughly varnished with shellac, to prevent absorption.

### Electrically Illuminated Tower Clocks.

*To the Editor of American Electrician:*

Sir—The subject of clocks is always an interesting one to me and illuminated tower clocks more so. I have noticed recent patents on the latter and wish to say that I experimented in that line some twenty years ago. My plan accomplishes three things. It does away with ground glass dials, which are expensive. It does away with inside lighting. It enables the time to be told at a much greater distance. I use but three lights on each dial, a red one on the end of the minute hand, a green one on the hour hand and a white frosted or a yellow one on the center post. No effort is made to light up the figures on the dial; the time is told by the position of the red and green lights on the hands as they revolve around the white one on the center post, just as blind man can tell the time by feeling the hands of a watch. I used a five-foot dial and had a number of assistants, mostly boys, strung out in a line for half a mile and could tell the time within a minute or two at 2,400 feet. The lights were changed by an assistant at random a number of times, all of us keeping a record, the boys singing out the time instantly.

The lamps may also be rigged out on light extension pieces, so as to double the length of the hands, making the dial appear twice as large and, of course, increasing the distance at which it may be seen. I took no patent on this, but give it to the world for what it may be worth

### Smoke Consumption and Economy of Fuel.

*To the Editor of American Electrician:*

Sir—I have recently seen the "Advance Sheets" of some consular reports dated May 20th, 1899, and the first article is headed "Smoke Consumption and Economy of Fuel," in which Consul General Mason of Berlin, Germany, tells about what he evidently thinks is a new and important system, although it consists simply of hollow grate bars carrying to the fire a hot air blast. If Mr. Mason knew what an egregious ass he made of himself in that article, in the eyes of all who are posted on boiler furnace systems, he would avoid hereafter being quite so ready a tool of those who give a new name to an old method and then by the use of the names and influence of men of position seek to fool someone into buying a patent which is not worth the paper it is written on.

That so-called "new system" of Mr. Paul Cornelius is in fact a very old system, and, in the nature of the case, not at all satisfactory as a smoke preventing system, or desirable from the economical standpoint in burning bituminous coal of any grade.

The spectacle of one of the Consul Generals of the United States looking at such an apparatus and gravely recording in a "Report" its freedom from smoke when burning "Coke Dust," makes it very clear that Mr. Mason's anxiety to serve his countryman has been taken advantage of by a shrewd "promoter," who seeks to catch the gullible capitalist.

If they succeed in getting the government of Sweden to pay any considerable sum for what Mr. Mason styles, in parrot-like form, the "Swedish patents," that will be a double-header sale, for both the patent and the people of Sweden will be sold.

# Electrical Catechism

*332. How much is the pull on a single wire carrying current through a magnetic field?*

The pull (measured in dynes) is found to be equal to the product of the strength of the field (measured in lines of force per square centimeter) by the strength of the current (measured in the C. G. S. unit, which equals ten amperes) and by the length of the wire (in centimeters) which is in the magnetic field. Using grammes, centimeters and amperes, the pull in grammes equals the product of the amperes by the number of lines of force per square centimenter by the number of centimeters length of wire in the field and divided by 9,810. Using English measures, the pull in pounds equals the number of lines of force per square inch multiplied by the number of inches of wire in the magnetic field multiplied by the number of amperes through the wire and divided by 11,303,000.

*333. How much is the pull on the whole surface of an armature of a motor?*

If the magnetic field is assumed to be of uniform density, we may calculate the pull on each wire as above and multiply by the number of wires on the armature, remembering that the current in each wire is only half the whole current through the armature of a two-pole machine, and considering as the length of each wire only that part that is on the cylindrical surface, neglecting that on the ends. An easier method is to consider the number of lines of force through the armature. The number of dynes pull on the surface, measuring in C. G. S. units, equals the product of the number of lines of force through the armature by the number of wires and by the current divided by the circumference of the armature. The pull measured in grammes equals the product of lines of force by amperes by number of wires divided by the circumference, multiplied by 9810. The pull in pounds equals the number of wires by the current by the lines of force divided by 35,525,000 times the diameter in inches.

*334. Give an example of calculating the pull on an armature.*

Take the case of an Edison bipolar motor taking 80 amperes at 117 volts running at 1400 revolutions per minute, having 200 armature wires and 2,500,000 lines of force through the armature, which is 6½ in. in diameter. The pull on the surface is then

$$P = \frac{200 \times 80 \times 2\,500{,}000}{3.14 \times 6.5 \times 35{,}525{,}000} = 200 \text{ pounds.}$$

*335. What is meant by torque?*

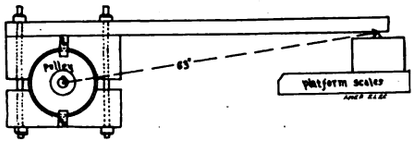
By torque is meant the pull at unit radius. In metric system it means the number of dynes pull at a distance of one centimeter from the center or the number of grammes pull. In English measures it means the number of pounds pull at a radius of 1 in. or of 1 ft. Torque is measured in dyne-centimeters, gram-centimeters, pound-inches or pound-feet. In the case of street railway motors it is common to speak of the torque exerted on the circumference of a wheel 33 in. in diameter.

*336. How is the torque calculated?*

The torque in pound-feet equals the product of armature wires by amperes by lines of force divided by 852,500,000. For example, the torque in pound-feet of the above machine is

$$T = \frac{200 \times 80 \times 2{,}500{,}000}{853{,}500{,}000} = 48 \text{ pound feet.}$$

*337. Can the torque be calculated from the power taken by the motor?*



It can, roughly. The above machine takes 80 amperes at 117 volts, or 9,360 watts, which, divided by 746, is 12.55 horse-power; this multiplied by 33,000 gives 414,150 foot-pounds as the energy taken by the motor and given out by it if there were no losses in the motor. Since it makes 1400 revolutions per minute, the velocity at a radius of 1 ft. is 6.28 times 1400, or 8792 ft. per minute. Dividing the 4.4,130 foot-pounds by this velocity gives 47.1 as the pull at the radius of 1 ft. This agrees closely with the 48 pound-feet of the previous calculation.

*338. How can the torque of a motor be actually measured?*

The easiest way is to stop the motor, remove the belt, attach a spring balance to the pulley in such a way as to measure the pull at its periphery. Then, using a rheostat to control the current, send as much current through the armature as is taken in regular working, and measure the pull on the spring. Another way is to clamp a piece of wood to the pulley and arrange a platform scales so as to measure the downward thrust when the motor attempts to start; the scales then weigh the pull at a radius equal to the distance from the center of the shaft to the point where the lever touches the platform. There are several forms of transmission-dynamometer for measuring the amount of power developed by actually weighing the difference between the pull on the tight and on the loose sides of the belt.

*339. How can the power of a motor be measured?*

A prony brake is the most convenient method for general use. A simple form

A SIMPLE FORM OF PRONY BRAKE.

suitable for short tests consists of two blocks curved to fit the pulley and having a long arm and two bolts, as suggested in the figure, and two guide pieces on each side to keep it from slipping off sidewise. The end of the arm rests upon a sharp edge, which is supported upon the platform of a scales. The scales measure the torque at a radius equal to the distance from the center of the shaft to the knife-edge. If in a given case the pressure is 5 lbs. at the distance of 63 in., the torque is 315 pound-inches, or 26.25 pound-feet.

*340. Can the work done by a motor be measured by such a device?*

It is only necessary to let the motor run and then measure the pressure on the scales and also measure the speed. The work equals the product of the torque by the velocity at that radius. The calculations are simplified if the distance is 63 in., for then the circumference of the circle passing through the knife-edge is 33 ft., so that 1 lb. pressure at 1 000 revolutions per minute would mean 33,000 foot-pounds, or 1 horse-power. In such a measurement it is desirable to lubricate the blocks by soapy water or by a ham-rind, to prevent jerky action.

*341. Give an example of a test on a prony brake.*

Suppose the arm is 63 in. long, the pressure is 8 lbs. and the speed is 1400 revolutions per minute. Then the point at the knife-edge would travel 33 ft. in each revolution, which at 1 400 per minute would be 33x1 400, or 46,200 ft., per minute. Now, multiplying this by 8 gives 369,600 foot-pounds work done per minute. But 33,000 foot-pounds make one horse-power, hence dividing by 33,000 gives 11.2 as the horse-power.

*342. How can the efficiency of a motor be determined?*

Connect an ammeter in series with the motor and a voltmeter across its terminals, so as to measure the electrical energy supplied. Measure the mechanical work given out by the prony brake. Reduce both to horse-power or watts and divide the work given out by that absorbed.

*343. Give an example of measuring efficiency.*

Suppose the motor measured in No. 340 takes 84 amperes at 117 volts. The electrical energy taken is then 84x117, or 9828 watts, or 13.2 horse-power. Dividing that delivered by that received gives 11.2÷13.2=0.85, or 85 per cent., as the commercial efficiency of the motor at that load.

*344. How can the efficiency at different loads be determined?*

By clamping the two blocks together more or less tightly, the load may be varied, and so the electrical and mechanical power may be measured for different loads.

*345. How can one tell how much power a motor is giving out when it is in regular service driving machinery?*

If the motor can be cut loose from the regular load and a brake applied, the efficiency may be determined for different currents as above indicated. Then by measuring the current and voltage while it is working at its regular load and multiplying by the efficiency of the motor for such load, we can determine the power being delivered.

# Queries and Answers

Readers of the American Electrician desiring answers to inquiries through this department are requested in every case to give their full names and Post Office addresses. The number of inquiries is so great each month that complete answers to all would fill many pages of the American Electrician. A large number of these inquiries, such, for example, as requests for the size of wire for a given motor, are not points of general interest; others necessitate a request for further data before they can be answered; still others are so general in character that they can only be answered by the reading of a book. The publication of all these queries and answers would fill these pages with much matter of no value to the general reader. All questions will be, so far as possible, answered by mail, and only those bringing out valuable points, sufficient in number and length to fill this page will be published. Readers who do not receive a response to their queries may attribute it to their failure to give a proper mailing address.

---

In the experiment of heating an iron rod in a bucket of water by electricity, to a red or melting heat, what salt is added to the water? Does this act chemically, or is it just to increase the conductivity of the water? E. T.

Ordinary common salt or sulphuric acid may be used. The action is not chemical, the purpose of the salt being simply to reduce the resistance.

Do you have to use two pairs of lamps with each pair in series and two grounds for a ground detector on the three-wire system? E. H. S.

No. Use 4 lamps in series with one ground between the two middle lamps and connect one of the outside lamps to the positive and the other to the negative main.

(1) Can an ammeter with a range of from zero to 10 amperes be used on a primary circuit of 1000 volts and read accurately?

(2) If you cut a voltmeter in a circuit ahead of the ammeter, will you get the current through the voltmeter and will it have any effect upon the reading of the voltmeter and vice versa?

(3) How can I find the current that a motor takes, horse power, voltage and speed being given? A. C. R.

(1) Yes, if it is built for alternating current. (2) The ammeter will not indicate the current going through the voltmeter, but the latter is, as a rule, negligible, owing to its small amount. The ammeter will have no effect upon the reading of the voltmeter, nor vice versa. (3) Multiply the horse-power by 800 and divide by the voltage.

Will you give the rules in designing transformers for the size and amount of wire? I have a number of old transformers to rewind and wish to change the secondary voltage from 52 to 104 and from 52-104 to 104-208. What is the effect of using transformers wound for 125 cycles on 60 cycles? Can you give me the name of a book covering the above in a practical manner? E. L. E.

To double the voltage of the low tension side of transformers the number of turns in the secondary should be doubled. The cross-section of the wire will then have to be reduced at least 50 per cent., which is 3 numbers on the Brown and Sharpe gage, and as a rule somewhat more, owing to the greater amount of insulating material. Thus, if the original size of wire in the secondary is No. 8, to get double the voltage it will have to be rewound with practically No. 12 wire, using twice as many turns. Transformers built for 125 cycles can be used on 60 cycles. See the American Electrician, May, 1899, page 225. A good book on transformer design is "Haskin's Transformers, their Theory, Construction and Application." Price $1.25.

Suppose I had a switchboard containing several circuits and that I found I had a heavy ground or short circuit, what would be the best way to determine on what circuit or where the ground is? Assuming I had ground lamps on switchboard and also not having them. Should I first try the generator for a ground, and not finding it on the machine, should I then try each circuit separately with galvanometer or voltmeter? By trying each circuit separately and having ground lamps, could I tell it on the ground lamps? J. B. F.

If each circuit is separately fused the location of a short circuit can be determined by the fuses which blow. In case of a ground proceed, as you have indicated, trying the ground lamps first with the machine alone in circuit and then adding the various feeders until the ground is indicated. In case you have no ground lamps on the board you can temporarily rig up a pair connected in series across the mains with their center connected to ground, or you can use a voltmeter, connecting one of its terminals to the ground and connecting the other terminal first to the positive main and then to the negative. If the voltmeter shows no voltage on either line there is no ground. If it shows full voltage when connected to the positive line the negative is grounded and if it shows full voltage when connected to the negative line the positive is grounded.

I have a small wheel-break interrupter run by a motor to connect with the primary of a 1-in. spark induction coil. It is 3 in. in diameter and is made to give 50 interruptions per revolution. No insulation is used except air insulation between the breaks. One of the terminals connects with the shaft, the other with a copper strip pressing on the wheel. Now, with the common vibrator interrupter I can get the longest spark, while with the wheel I only succeed in getting a much smaller one in spite of more pressure in the primary and increased interruptions. In fact, I can place my hand on the secondary terminals without much pain. Can you tell me what the trouble is? E. H.

The trouble is undoubtedly due in large part to the increased rate of interruptions. The current does not get time to get well started in the coil each time the circuit is made before it is again interrupted. The counter electromotive force of self-induction chokes back the current when the circuit is first made, and it takes perhaps one-tenth of a second for the current to reach approximately its full strength. You do not state the speed of your wheel, but if it gives 50 interruptions per revolution and runs at 300 r. p. m. it will give 250 breaks per second. If the make is the same length as the break the current will only have 1/500th part of a second to build itself up in the coil, which is altogether too short a time. The wheel should be run at a very low speed. Its contacts should also be shunted by a condenser, just as is the ordinary vibrator.

I have a small motor used to run on 110 volt circuits. The fields are shunt wound and the armature is a smooth drum core with 12 sections. I wish to make it run on alternating current. Would I be able to do so by having two collector rings attached to opposite sections of the commutator; would it be self-starting, and would it still run on direct current without disconnecting rings? M. N.

Your motor will work as a synchronous machine on alternating current circuits if you can run it up to the proper speed. Assuming that it is a bipolar motor, its speed must be 3600 r. p. m. for 60 cycle current and 8000 r. p. m. for 133 cycle current. It would still run on direct current without disconnecting the rings and would serve also as a rotary converter to change direct into alternating current, or vice versa. Its alternating voltage would be about 78 volts. It would not be self-starting and would have to be started by direct current or by external mechanical means. If it cannot be run at this high speed, there is no practical means of making it operative on alternating current unless it has a laminated field, in which case it can be rewound as a series motor and used with a. c. supply, but will only give an output considerably less than that as a direct current motor.

(1) How can I test the core loss in transformers?

(2) On what does the voltage, amperage and light giving power of incandescent lamps depend?

(3) What are arc light carbons made of?

(4) In what way do series incandescent lamps differ from those intended for parallel use?

(5) In electrical work, what is the use of a condenser? V. M.

(1) Obtain an alternating current wattmeter capable of measuring the core loss, which is about 3 to 5 per cent. of the rated capacity of the transformer, i. e. for a 20-light or 1 kw. transformer the core loss will be about 30 to 50 watts. The core loss can be measured on the secondary circuit, the primary being disconnected. (2) Upon the cross section, length and specific resistance of the filament. (3) See "American Electrician," June, 1899, page 295. (4) Series incandescent lamps have filaments much thicker, shorter and of a great deal lower resistance than multiple lamps, as they are designed to work on lower voltages, generally only 20 to 30 volts. They could be worked in parallel on these low pressures if it were desirable. (5) Condensers are used sometimes on alternating current circuits to compensate for lagging currents. In telephony they are quite generally used to let pass alternating, but choke back direct currents, and in telegraphy they are used to balance duplex systems for line capacity.

## THE MERSHON COMPENSATOR.

Many central station engineers, who are familiar with or even use the Mershon compensator for obtaining correct voltmeter indications on alternating current circuits, find it difficult to understand thoroughly how the instrument works or why it gives such correct results on loads of any magnitude or any power factor, doing away entirely with the need of pilot wires. The writer thought he knew

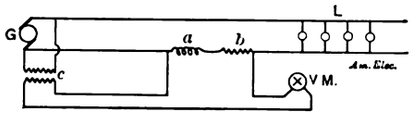

FIG. 1.—SIMPLE CIRCUIT WITH NO SERIES TRANSFORMER.

its principle, but when asked recently about it found he could not explain it properly and improved the opportunity to look up the patents, No. 551,982 and No. 571,839, issued to Mr. Ralph D. Mershon, covering the principle of this ingenious device. An explanation of the instrument in its two most simple forms may be given in untechnical language as follows:

Referring to the diagram shown in Fig. 1, G is the generator supplying a load, L, which may consist of motors or arc or

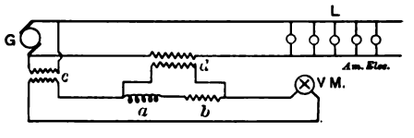

FIG. 2.—CIRCUIT WITH SERIES TRANSFORMER

incandescent lamps supplied through transformers. c is the instrument transformer designed to supply only the voltmeter, VM, and the purpose of the compensator is to make the voltmeter indication proportional to the pressure at the load center instead of at the generating station. In order to do this the compensator must subtract from the pressure upon the transformer, c, a certain amount proportional to both the ohmic and inductive drop in the lines and in step therewith, and this must be done whether the current in the lines is in step

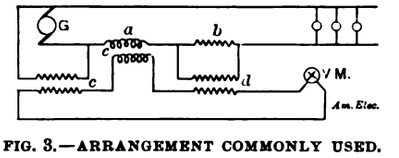

FIG. 3.—ARRANGEMENT COMMONLY USED.

with the electromotive force, lagging behind it or leading ahead of it. The arrangement indicated in the upper diagram is very simple.

Assuming that the machine is a 2000-volt generator and the transformer, c, has a ratio of 20 to 1, the normal scale reading of the voltmeter being 100 volts, then the proper drop is introduced by inserting at b an artificial resistance equal to 1/20 the total resistance of the line or feeder and at a an artificial inductance equal to 1/20 the total inductance of the line or feeder. The circuit from the instrument transformer, c, to the voltmeter, VM, is passed through this resistance and inductance. When there is no load upon the line the small current given to the voltmeter will occasion no perceptible drop in this resistance and inductance, but as the main line load rises 1/20 of the main line drop occurs in this resistance and inductance and is subtracted from the voltage of the secondary of the instrument transformer, c. Thus, if the generator pressure is 2000 volts and the drop 100 volts, the drop in a and b will be 5 volts, which will be subtracted from 100 volts at c, giving the voltmeter 95 volts, exactly equal to what would be impressed upon lamps connected to a 20 to 1 transformer at L. It will be noticed that if the current in the main line lags behind the impressed electromotive force, thus increasing the reactive drop, it will do the same in a and b, increasing the effective drop in the path of the voltmeter.

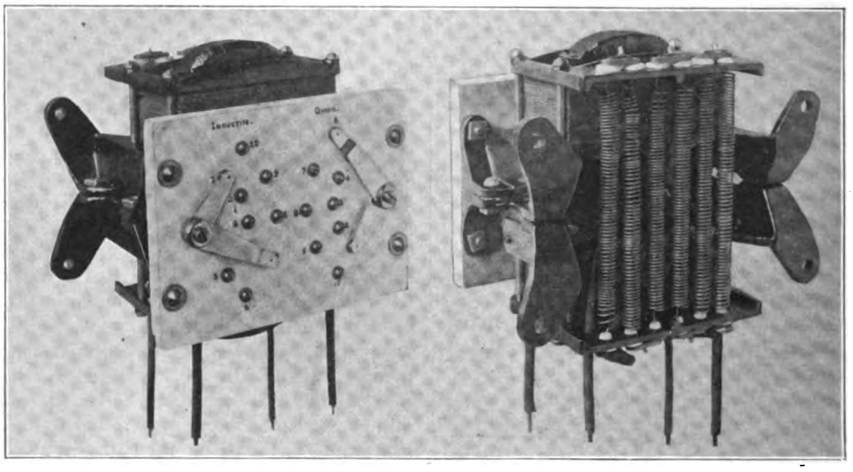

FIG. 4.—FRONT AND REAR VIEWS OF THE SERIES TRANSFORMERS, OHMIC AND INDUCTIVE COILS AND ADJUSTING DEVICES AS ARRANGED FOR SWITCHBOARD USE.

The diagram Fig. 2 gives the circuits as they would be when a series transformer is used in the main line to avoid the necessity of connecting the instrument electrically with the high tension circuit. In this case the arrangement is exactly the same except that a and b are supplied with current proportional to and in step with that in the main line by means of the series transformer, d. c is as before, the instrument transformer supplying VM through a and b. The drop in the latter is made proportional to that in the line by means of proper transformer ratios, so that the instrument gives an indication proportional to the voltage at the distant end of the line. In case of a feeder running to one large step-down transformer or even supplying scattered smaller transformers, the inductance and resistance of a and b can be made proportional to both the properties of the line and transformer, so that the drop of both can be compensated for, the instrument giving the pressure upon the secondary system at all times, even with heavy lagging currents.

There are many other possible arrangements of the circuits for accomplishing the same purpose, but of them all the Westinghouse Electric & Manufacturing Company prefers to use commercially that indicated in Fig. 3. Here again, G is the machine supplying the load, L and c is the instrument transformer for the station voltmeter, VM. The inductance, a, and resistance, b, are in this case inserted serially in the high tension circuit and their drop is introduced into the voltmeter circuit by means of two small transformers, e and d. As the inductance, a, is wound on an iron core, this core is used as that of the transformer of which the inductive winding, a, becomes the primary. The primary of d is shunted around the non-inductive resistance, b, its secondary being connected in series with the secondary of the inductive transformer, e, as well as the instrument transformer, c, and the voltmeter. The transformer, e, has an open magnetic circuit to increase the self induction, while d has the usual closed core. In this arrangement c gives to the voltmeter a pressure proportional to that of the generator, while e introduces into the voltmeter circuit a drop proportional to and in step with the inductive drop of the line, and d introduces into the voltmeter circuit an e. m. f. proportional to the ohmic drop in the line. The result is that the voltmeter indicates the pressure at the distant center of distribution.

The resistance and inductance apparatus as made by the Westinghouse Company is shown in Fig. 4. Here the non-inductive resistance consists of helical wire coils of the ordinary form and the two small transformers indicated by the letters d and e in Fig. 3 may be seen on the back of the marble slab. Both the ohmic and inductive drops are made adjustable by the rotatable contacts shown, so that the instrument can be set at any time for the properties of the line to which it is connected.

## THE SCIENTIFIC TREATMENT OF IMPURE BOILER FEED WATERS.

BY J. H. PARSONS.

The subject outlined above is one of great importance, on account of its perplexity, and hence commands the immediate and careful attention of every steam user. It involves interests sufficiently extensive to give it great importance and demands the utmost exertions of engineers towards the solution of its problems and the provision of remedies to counteract the evil effects of impure boiler feed water. The subject is partly a chemical and partly a mechanical one, and so requires a study from the theoretical as well as the practical side.

Compounds and water purifiers, both chemical and mechanical, frequently fail to work, for several reasons. Often the steam user expects and looks for too much A successful treatment may not be necessarily a complete annihilation of all troubles. No one compound can be made to do work for all waters and it is absurd for any one to offer such a compound for sale. Even were it possible to prepare a standard remedy, the dose and form of application would not suit all cases. Where lime and magnesium exist in the water in the form of carbonates without sodium salts, it would be an easy matter to treat the water successfully with a simple remedy. But suppose the lime to be in the form of a sulphate and the magensium a carbonate, with a large excess of the former, the treatment could not be a success without a more energetic and thorough transformation of the salts. Then again in the presence of chlorides the magnesium salts change to chlorides, which under heat liberate hydrochloric acid and this acts on the metals of the boiler. This condition has to be understood, and we must determine whether it will arise when the special sample of water is heated, before a formula for a good antidote can be devised.

In the case of iron pyrites, sulphate of copper and sulphate of iron in water under heat, free sulphuric acid is often produced in large quantities. After careful laboratory tests we can determine how much of the acid is formed under heat and pressure, how much of the acid will unite with the lime and magnesium contained in the water, and how much will remain as free acid. Different reactions require different remedies. The chemist must use great care in preparing each formula. He must use the results of experience with boilers with his knowledge or chemistry to make the formula a sure, economical and safe one. He must not put into the preparation anything which will of itself decompose into, or form with the salts in the water, a troublesome element.

An analysis of a sample of water may be correct, but if misinterpreted or if the final results which take place in the water under heat and pressure are misunderstood, it becomes a matter of guesswork and the remedy, if made, is not a scientific one, but a conglomeration of half a dozen, often more, ingredients sent out with the hope that some one or two in the lot will hit the nail on the head or do the work required.

It is only by a careful preliminary study of the water used, and by the use of a remedy which will precipitate each of the scale forming salts contained in the water in the form of a non-crystalline or non-adhering mud or silt, at the same time neutralizing the corrosive elements that it is possible to prevent incrustation and corrosion. By this method of treatment the rapid deterioration of the metallic sheets of the fire surfaces of the boiler and the danger of explosion are lessened.

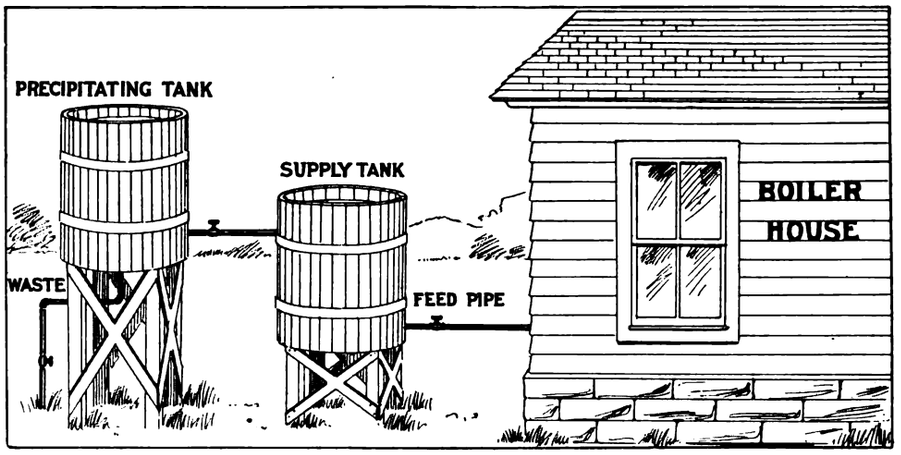

FIG. 3.—ARRANGEMENT OF TANKS AND PIPING FOR FEED-WATER PURIFICATION.

FIG. 1.—SCALE FORMED OF SULPHATE OF LIME.

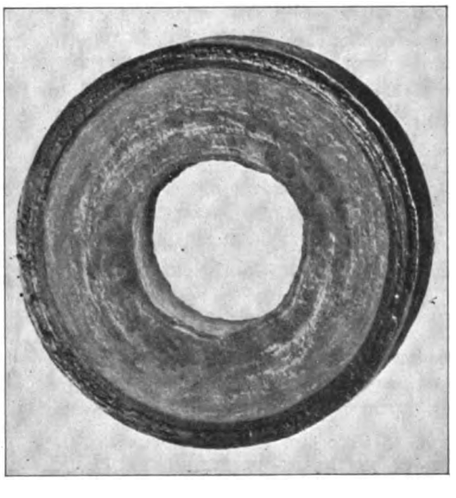

FIG. 2.—A TUBE FILLED WITH CARBONATES.

Fig. 1 shows a scale formation composed largely of sulphate of lime. Fig. 2 shows a scale formed from magnesium carbonate and from magnesium sulphate.

For waters very heavy in salts of lime and magnesium (sulphates and carbonates), silica, iron and salt, the writer would recommend a treatment to secure the precipitation of scale forming silts and neutralizing corrosive elements without the aid of heat, a precipitating tank being used.

When properly treated, generally 85 per cent. (often more) of the scale forming salts can be precipitated and all of the corrosive elements neutralized before the water reaches the boiler. By doing this properly and drawing the precipitate out before feeding to the boilers, the trouble universally experienced when using impure feed water can be prevented.

There should be two tanks, each holding about the day's supply. The water from the first, or precipitating tank, after being treated with our remedies, may be run into the second, or supply tank, and from this fed to the boilers, while the first tank, filled again, is being treated and settled for the next day's supply. The waste pipe with stop valve should be placed in the lower extremity of the tank. One tank will answer if the supply water is drawn from it after the precipitate has had time to settle and has been drawn off. The illustration shows a plant erected by the J. H. Parsons Chemical Company of 1509 Masonic Temple, Chicago, Ill., capable of treating waters from 500 gns. of total solids per gallon down to 25 gns. per gallon, the remedy being made to suit each water after the analysis is made.

## THE BRUSH MULTI-CIRCUIT ARC DYNAMO.

In the course of the first ten years' development of series arc lighting, the size of generators gradually increased from a few lights up to 65 lights, requiring approximately 3000 volts from the dynamo to operate the circuit. At this point the building of larger arc dynamos was checked for the want of better line insulating materials. These, however, were found by a few electric light companies, and during the years of 1893 and 1894 the Brush Electric Company brought out its 125 light arc dynamo, 6250 volts, 9.6 amperes, 500 r. p. m., known originally as No. 9, and later as No. 11. The companies had much trouble in introducing these machines, due to the poor line insulations upon which many of them were operated, causing many burn-outs and troubles on the circuits. What was desired was a machine on which a larger number of lamps could be operated without increasing the potential in proportion to the number of lamps run. The multi-circuit arc generator filled this want.

The Brush arc generator was particularly well adapted for the multi-circuit system of arc lighting, the armature being constructed in a sense as though it were several separate and distinct armatures or generators, each taking its share of the load, so that they could be readily divided up. In single circuit machines the separate armature divisions are connected directly in series with each other and all the lamps in one series, as shown in Fig. 1, thereby giving the maximum difference of potential across the terminals of the machine, as illustrated in the curve of potential gradients, Fig. 2.

The multi-circuit system, which is covered by patents, consists, broadly speaking, of dividing up the lamp load into several circuits, and interposing the different sources of electromotive force, or the different armature divisions in the Brush arc generator, between the different lamp circuits all in series. Taking, as a practical example of this, the original 125 light Brush arc generators with three separate commutator rings, generating upon each one of these practically 2200 volts, the three connected in series will give 6600 volts between the outside brushes connected to the armature, and allowing approximately 300 volts for fields, there will be left 6300 volts at the machine terminals. The drop of potential in the 126 lamps, going around the complete circuit, will absorb this voltage, as indicated in Fig. 2.

To employ the multi-circuit invention to the best advantage upon this generator, the circuit of 126 lamps should be divided into 3 equal circuits of 42 lamps each, and these interposed between the different commutators in the following manner:

Starting in at the negative terminal of the machine, the circuit goes through the fields and thence on to the negative brush on the first section of the armature, through this section and out onto a circuit of 42 lamps; thence it comes back to the negative brush on the second section of the armature, passes through this section to the positive brush, through a second circuit of 42 lamps, and back to the

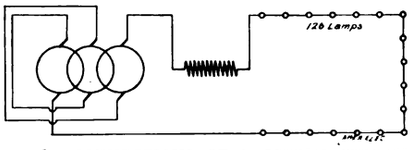

FIG. 1.—CONNECTIONS OF A SINGLE CIRCUIT ARC MACHINE.

negative brush, on the third section of the armature, through it and out to the positive brush through the third circuit of 42 lamps, and returns to the negative terminal of the machine whence it started. This arrangement is shown diagramatically in Fig. 3.

It is quite evident that, considering the voltage generated in the different arma-

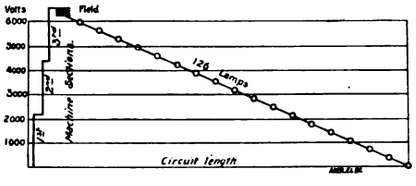

FIG. 2.—RISE AND FALL OF POTENTIAL IN AN ARC CIRCUIT.

ture circuits as plus, and the drop in the different lamp circuits as minus, there will be the following voltages around the circuit:

$$-300 + 2200 - 2100 + 2200 - 2100 + 2200 - 2100 = 0.$$

The voltage between any two of the positive brushes will not be over 300, and the same will be true of the negative brushes. The maximum difference of potential under these conditions will be that between the positive of the third circuit,

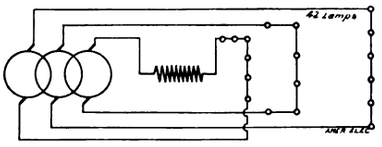

FIG. 3.—CONNECTIONS OF A MULTI-CIRCUIT ARC MACHINE.

and the negative brush of the first section of the commutator, being made up as follows: 2100 volts in line, and 300 volts approximately in the fields, making a total of 2400 volts. The curve of potential gradients for this condition is shown in Fig. 4.

While the generators which the Brush Company was building at the time this in-

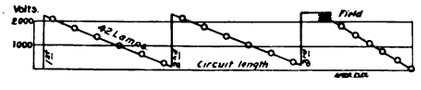

FIG. 4.—RISE AND FALL OF POTENTIAL IN A MULTI-CIRCUIT LINE.

vention was made are perfectly applicable for multi-circuit running from a scientific point of view, from a commercial point of view they are not particularly well adapted to it, due to the fact that it requires too many small lamp circuits.

Six thousand volts on arc circuits are to-day run in a great many cities, and have been run for a long time, and the advantage to be derived from dividing up one of the earlier machines is comparatively slight, for the simple reason that it increases the cost of the arc circuits, and also decreases their efficiency, owing to the increased amount of wire, except in the case of factory and near-by lighting, where there will be no appreciable extra cost of construction and the higher voltage is objectionable. The multi-circuit device can for such cases be attached to any of the earlier generators.

The particular advantage to be gained from the multi-circuit generator is in the station itself, in reducing the number of generators required to supply current to a given number of arc lights with a given maximum voltage, making large savings in the power, floor space, belting, attendance, oil, etc., over many small generators. Another advantage lies in the operation of circuits, due to the fact that it is not necessary that the loads should be divided equally between the two circuits on one machine, but upon machines below 8500 volts, it may be divided in any manner desirable between the circuits, the one regulator keeping the current constant on both circuits.

In the operation of multi-circuit machines, a ground on one circuit or two grounds on one circuit will not affect the operation of the generator. A bad ground upon each of two circuits very seriously affects the operation of the multi-circuit generator, but in this case the two circuits can be readily put in series with the other and the machine run as a single circuit dynamo.

The only advantage of operating two separate arc generators in series upon the multi-circuit plan—as is done in some stations—with the loads divided and interposed between the two would be in the case where one of the circuits was larger than what a single machine would carry, and the other somewhat smaller, the two circuits making the full load or less for the two generators. A disadvantage of this arrangement is the fact that grounds upon the two circuits of a multi-circuit system or group of machines seriously affect the operation of the same, besides which there is some difficulty in getting two automatic regulators to run satisfactorily in series with each other. The best plan in such cases is to cut out one regulator and let the other one care for variations in load.

### BREAKING ARC LIGHT CIRCUITS.

It has been argued against this multi-circuit plan that the full voltage of all sections of the machine is concentrated across any break in the circuit, increasing the strain on the insulation in case of such a mishap.

There is only one practical way for determining wthout elaborate apparatus the instantaneous voltage upon breaking a circuit—namely, the distance which the current will jump. The best method is by connecting needle points, carefully set a given distance apart, across the break, and breaking the circuit many times,

Digitized by Google

bringing the needle points gradually closer together until the current jumps.

Fig. 5 gives a curve of the distances between needle points and the direct voltages which will jump over these distances. This curve has been arrived at after a long set of experiments, very carefully made, in which Brush arc generators were loaded up on a resistance and lamp load with needle points set at a

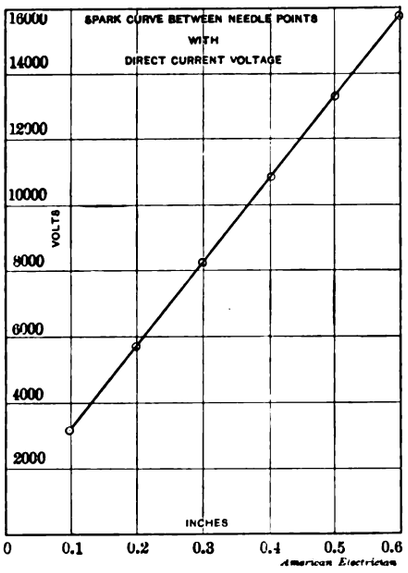

FIG. 5.—SPARKING DISTANCE OF DIRECT VOLTAGES IN AIR.

given distance, and the voltage slowly raised until the current jumped between the needle points.

With this curve as a basis, tests have been made upon breaking a single circuit Brush arc machine in the middle of a lamp load, the capacity of circuit being small. The results showed that the voltage of the machine terminals would not rise 5 per cent. above the maximum voltage which the machine would give under normal operation at full load, and that

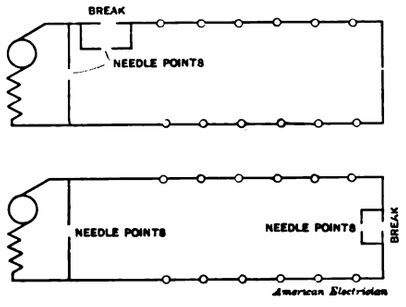

FIG. 6.—CONNECTIONS OF DYNAMOS FOR VOLTAGE TESTS.

at the break, about 60 to 75 per cent. of the normal voltage of the machine would appear, the balance evidently being used up in lamps and line. The same results were found upon breaking the circuit at one end.

Fig. 6 gives diagrams of connections for these experiments. Experiments of the same nature were carried on with a multi-circuit generator, showing a maximum voltage across the break in line, with circuits equally loaded, less than 50 per cent. above the voltage of one section of the generator.

These results are rather surprising, but upon looking into the principles of the open coil arc generators it may readily be seen that the opening of the circuit instantaneously places an infinite load upon the machine, which draws the point of commutation back under the brushes and causes the machine to flash, short circuiting the armature with no damage, and relieving the electrical strain upon the line. In other words, the flashing of an open coil machine acts very much the same as the safety valve on a boiler. The officials of the Brush Company have arranged to show prospective customers at short notice at the Lynn Works of the General Electric Company experiments of this nature, so that they may be thoroughly satisfied that such is the case.

### THE OIL REGULATOR.

To get a better control of the current strength of the Brush arc machine the

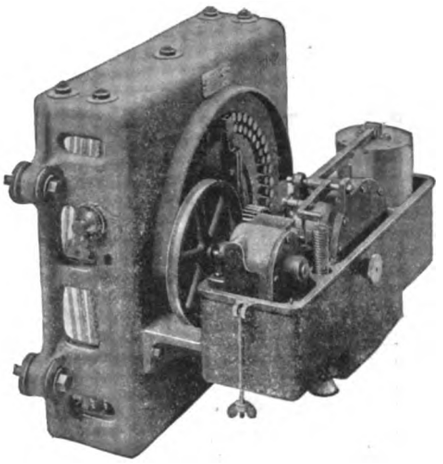

FIG. 7.—THE OIL REGULATOR.

General Electric Company has developed a new type of regulator known as "Form 2," for use instead of the magnetic clutch regulator, until recently in service on such machines. The new instrument, like the old, varies the resistance of the shunt to the series field winding and also adjusts the position of the brushes on the commutator, and is mounted in the same place on the machine, namely, below the commutator and in front of the rheostat in a cast-iron enclosing case. It requires no wall controller. The mechanism consists of an oil pump driven constantly by a belt from the armature shaft and supplying oil through a two-way valve to a rotary piston or vane, the motion of which is communicated to the rheostat arm and brush-rocking mechanism. The position of the valve is determined solely by the magnetic pull of the main solenoid in the series circuit, the restoring force being the usual spring. With an excess current the valve is displaced in one direction, admitting oil under pressure to one side of the main vane and allowing it to be discharged from the other side, while with a current less than normal the reverse action takes place. In the normal position the oil leaks past the valve ports.

The chief advantage of the improved regulator is the fact that the rapidity of its motion is to a certain extent dependent on the variation of the current from normal. Thus, in case of a sudden change

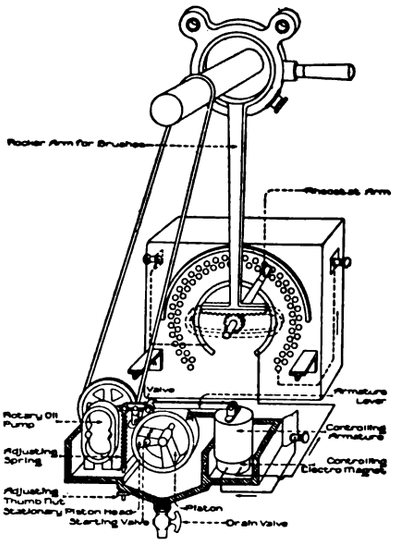

FIG. 8.—GENERAL SCHEME OF OIL REGULATOR.

of load the motion of the regulator is at first rapid, and slows down gradually as normal current is approached. This avoids the hunting or pumping action which occurs with a regulator like the old clutch, which moves at full speed or not at all, and constantly overruns, "hitching" the mechanism back and forth.

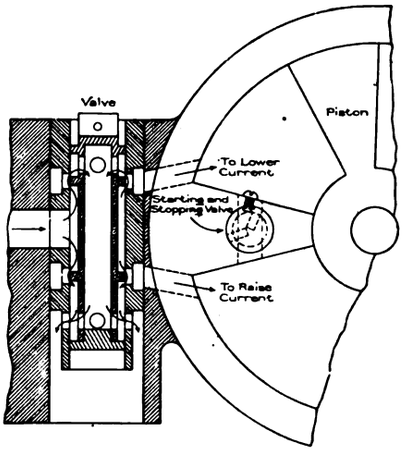

FIG. 9.—SECTION OF OIL REGULATOR VALVE.

There are obviously in the new regulator no sparking contacts and few moving parts, the latter being almost entirely in the enclosing case and partly surrounded by an oil bath. A safety valve is provided to relieve the pump from excessive pressure. The new regulator may be substituted for the former instrument either with or without a new rheostat.

## TURBINE WHEELS FOR DIRECT COUPLING TO ELECTRICAL GENERATORS.

Unfortunately for the builders of hydraulic power plants, the problem of designing water wheels and generators to run at the same speed so that they may be direct coupled is in many instances more difficult than that of bringing the speeds of dynamos and engines together.

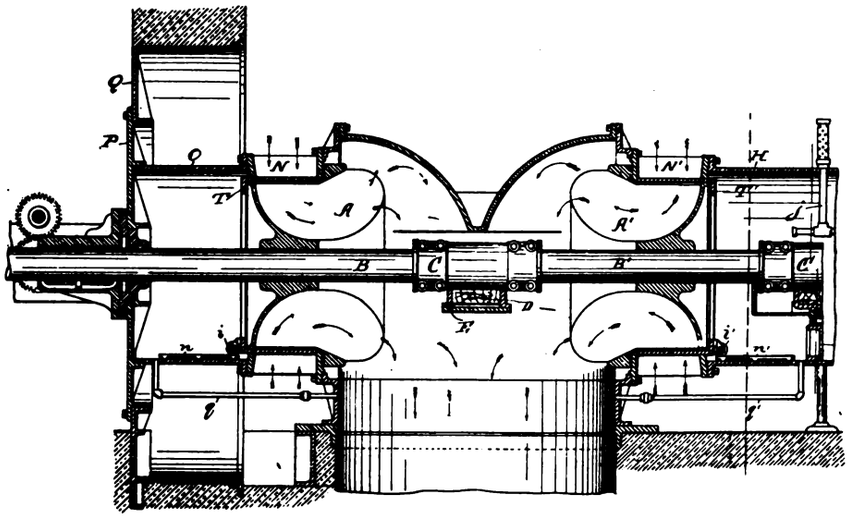

FIG. 1.—VERTICAL SECTION OF VICTOR TURBINES.

Where the head of water is high, from 100 ft. up, the problem is an easy one. A plain bucket or impulse wheel is generally used in such cases and a considerable range of speeds in revolutions per minute, comparable with those in dynamo work, can be obtained by varying the diameter of the wheel, while a range of capacity can be obtained by varying the number of jets acting on one wheel, or the number of wheels on the shaft. As the wheels are narrow, several of them can be readily put on one shaft without occupying much space.

In case of low heads, turbine wheels must be used to obtain any considerable power in a given space and the peripheral speed of these bears such a definite relation to the head of water that a large number of revolutions per minute would make them of ridiculously small diameter and power. In case of direct coupled engine sets the problem becomes more easy in the larger sizes as large dynamos can be economically built at common engine speeds. Single turbine wheels of high powers at low heads cannot be built to run at dynamo velocities, so that heretofore it has been considered necessary to gear a number of vertical shaft turbines to a horizontal dynamo shaft running along immediately above them. The advantages of direct coupling so greatly outweigh this clumsy arrangement that it is far preferable in most cases to place a number of horizontal shaft wheels in a row on one dynamo shaft.

To illustrate the problem, suppose the generator is of 1000 h.p. or 750 k.w. capacity. If, as is usual, it is an alternator, it should run at about 300 r.p.m., as lower speeds give either very crowded poles or an excessive diameter and short axial length of the armature and field magnet structures. With a head of 40 ft. this output could be obtained with a pair of 30 in. wheels of the type described below. If the head is only 30 ft. two pairs of 27 in. wheels must be used; if the head is only 25 ft. three pairs and one single wheel 24 ins. in diameter must be used, all connected on one shaft.

Direct coupling in such cases necessitates, as a rule, horizontal shafts, as the difference between tail water level and high back water and the maximum height of a draft tube is insufficient to place many turbines. The problems of compactly arranging the wheels so as to economize floor space and of coupling them together, and supporting them and their cases so as to keep them in accurate alignment, as well as of operating their numerous speed controlling gates, have been solved for one make of wheels in a most thorough manner by Mr. A. C. Rice. His designs in this direction, as shown in a recent patent No. 621,141, are described and illustrated below.

The wheels for which these improvements were designed are the Victor turbines, as made by the Stilwell-Bierce & Smith-Vaile Company, Dayton, Ohio, and the patents covering the improvements are assigned to this company. The runners of Victor turbines are of the inward, radial flow type with horizontal axial discharge, and those for low heads are as a rule set in an open flume of masonry. An idea of these parts and the improvements in them can be gained from an examination of Fig. 1, which shows a vertical section through a pair of turbines. A and A′ are the runners, the course of the water through them being clearly indicated by the arrows. The two wheels are respectively right and left handed and discharge into a common central draft tube. N and N′ are the guide chutes which give the water a tangential motion tending to turn the wheels. The gates which control the flow of the water and thereby regulate the speed of the wheels are of the register type, cylindrical and sliding directly between the guide chutes and the runners, in which position their throttling of the flow reduces the efficiency less at part gate opening than at any other position in the flume.

The solution of the problems outlined above, viz., economy of floor space, support of all parts in alignment and the operation of the gates, is as follows: In the first place, the dome cylinder, O, which must be provided to receive the gate, T, of the left-hand wheel, is contained within the bulkhead wall between the flume and dynamo room, the opening in the wall being closed by a steel flume head cover, P, bolted to the flume head, Q. This economizes in length a distance equal to the thickness of the wall.

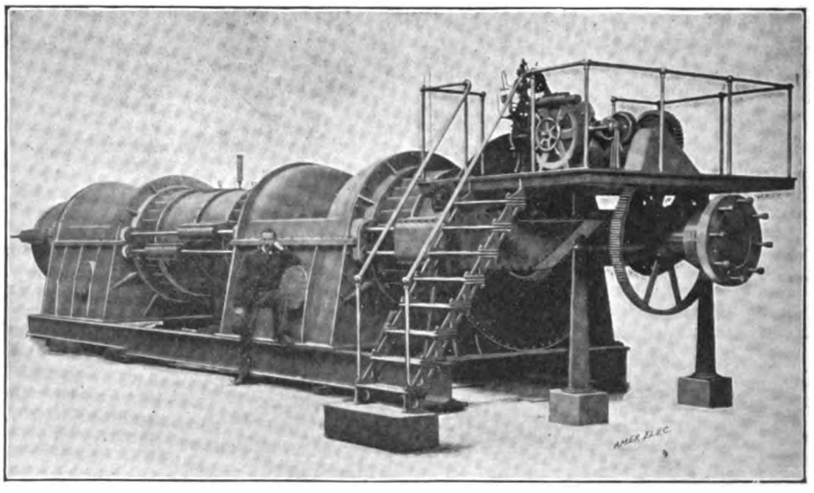

FIG. 2.—VIEW OF FOUR WHEELS ASSEMBLED WITH GOVERNOR.

The gates, T and T′, slide horizontally in the dome cylinder, T moving to the left and T′ to the right to increase the flow of the water. They are supported on roll-

Digitized by Google

ers, i and i', running on tracks, n and n'. The dome cylinders into which the gates move when opened are drained of water by means of the pipes, q and q', so as to allow a free movement of the gates. The latter are driven back and forth in response to the demands of the governor by means of horizontal rods running along both sides of the turbines parallel with the shaft, which rods are shown in the photographic illustration of a group of these wheels, Fig. 2. There are two of these rods on each side of the casings, one rod of each pair being attached to alternate gates so that the gates of two wheels discharging into one draft tube are moved in opposite directions. These rods run through packing boxes in the flume head cover, there being within the flume and subject to the action of gritty water, no gears or racks or other wearing parts of the gate operating mechanism, the whole of which is open and free of access in the dynamo room.

The coupling of the shafts is another valuable point. The left-hand runner shown in the figure is mounted on shaft, B, while the right hand is on another section of the shaft, B', and still another section may be coupled to the right. The coupling consists of a split coupling sleeve, C, which also is utilized as a water bearing on the support, D. This makes a greater length of shaft for both the bearing and coupling unnecessary.

The dome cylinder, H, at the right, which contains two gates, is bolted to the chute cases of the wheels to both sides of it, thus keeping them in alignment and supporting the whole from the draft chambers. The right hand water bearing, C', is contained within this dome cylinder and is lubricated by water brought down from the flume through the strainer, k, and pipe, j.

The whole arrangement is one admirably combining a simplicity and rigidity of the parts with a shaping of each piece which makes it easy to cast and simple to assemble, with minimum tool work. The advantages which the Stilwell-Bierce & Smith-Vaile Company obtains through these and other improvements particularly adapt Victor turbines for the driving of large generators, and in fact make this company in many contracts for the development of low heads for large generators direct coupled, the only builder which can bid under the specifications.

## THE PASSING OF THE STANLEY COMPANY.

A review of the history of the Stanley Electric Manufacturing Company was recently given by Mr. William Stanley to a local newspaper, from which the following points have been abstracted:

The Stanley Electric Manufacturing Company started on November 1st, 1890, with a capital of $25,000, and shipped its first goods the first of April, 1891. The original output consisted of transformers and general fittings for alternating current work, Mr. Stanley being a pioneer in this line, having constructed in 1885 and 1886 the first alternating current machinery adapted for the transmission of light or power for any considerable distance.

At the time of the first annual meeting it was shown that in the first six months of actual working time the company earned about $7,500. The capital was increased to $50,000, and the profit during the second year was $18,000, and during the third year $54,000. Afterward the company earned $76,000 yearly on transformers alone.

The Stanley Laboratory Company was also formed for the purpose of carrying on purely experimental work and developing and selling the inventions. In this company the principal stockholders were Mr. William Stanley, Mr. John F. Kelly and Mr. C. C. Chesney, the three men whose surname initials form the well known distinguishing symbols of many kinds of electrical apparatus, S. K. C. These engineers designed and perfected the inductor type of generator, since built in great numbers by the Stanley Electric Manufacturing Company, and did much other pioneer work, especially in alternating current motor and high tension problems.

Mr. Stanley estimates the total production of alternating current apparatus in the United States during the past year as follows: Generators and motors, 120,000 h. p.; transformers. 750.000 lights capacity; meters, 450,000 lights capacity. These three items alone approximately represent an investment of $3,000,000, while the other items which go to make up the alternating current systems easily bring the total value of one year's output of alternating current machinery up to $5,000,000. Of this amount the Stanley Electric Manufacturing Company did a business of between $500,000 and $600,000, its share of the total being no greater, not on account of its inability to obtain business, but because it was not equipped with shops and facilities for any more than this amount of work.

## EXHAUST STEAM HEATING.

After many years of experience on the part of quite a number of electric light and railway companies in the use of exhaust steam for the heating of building in cities, the fact seems perfectly established that a large measure of economy may often be derived from the utilization of this waste product. That steam from boilers can be successfully supplied for heating and power through long lines of pipe laid underground is attested by more than twenty years of direct steam service in cities and villages. Upon the awakening of modern electric development whereby central stations in nearly all cities and towns and have been erected, employing tremendous steam boiler capacity, attention was directed to the waste of an element which could be turned to very practical account.

All steam engineers know that only about ten per cent. of the energy of the steam supplied by a boiler is utilized in the engine and about ninety per cent. is wasted in the atmosphere or escapes in the hot water flowing from the condenser, if condensing engines are used. It was readily seen and demonstrated that the heat thus going to waste could be distributed and sold, and that the demand for steam heat in cities was even more reliable than the demand for electricity for lighting and for power. Because a company was organized primarily to develop and sell electric current it does not follow that it should be prohibited from engaging in a kindred enterprise which could be conducted under the same management and at very little additional expense, and result in great profit to the treasury of the corporation.

In fact, not to put to use this waste product argues a lack of intelligence and thrift on the part of a corporation so offending. Their rivals do not neglect similar opportunities, and a comprehensive view of the situation would lead to putting in force the same tactics. The gas companies could not live if they allowed their by-products to go to waste, and many branches of manufacture thrive and are enabled to pay dividends out of the proceeds from the sale of by-products. Then how can an electric company which can, as many companies are doing, pay all coal bills at the central station for the year out of the sale of exhaust steam during the heating season excuse itself for this lack of acumen?

Some companies are not favorably located to dispose of their steam in this way; that is an excuse, but they are peculiarly unfortunate on this account. With new installations it becomes vitally important to so locate the power plant that a ready market may be found for their exhaust steam. Indeed, in many cases it is a question whether heating from such a station should not become of primary importance, and the electric lighting or power be made incidental on account of being able to utilize only one-tenth of the output of the steam apparatus.

Some have objected to the plan because of the small amount of back pressure which is necessary in order to circulate steam through the underground pipes; but this is no objection, if, as may be readily made the case, the demand for exhaust steam calls for all that comes from the engines. If the revenue from the exhaust pays for the fuel, a difference in engine economy makes no difference. The steam being of a higher pressure becomes in addition a somewhat better conveyor of heat.

In whatever light the subject is viewed, and where the plant is located favorably for steam distribution, as near a district containing many office buildings or other consumers of large amounts of steam for heating, it would seem that business prudence would demand this conservation of waste products.

# New Apparatus and Appliances

## THE TOERRNIG LONG BURNING ARC LAMP.

Practically the sole cause of the revolution in arc lighting by which the enclosed lamp is driving out the older form of open arc is due to the reduced consumption of carbon and consequent lower cost of trimming. It is therefore manifest that a gain in this direction, other factors remaining the same, is a valuable advance.

The reduced carbon consumption is gained solely by checking the access of oxygen to the arc. In the ordinary enclosing globe there is some leakage of the gases around the bottle cap, which cannot be of one piece fastened hermetically to the globe, since it must be free to move laterally in order to prevent it from binding the carbon and there must be some clearance around the carbon to allow the passage of irregularities through the opening. In many forms the lower carbon comes through the bottom of the globe, giving some chance for leakage at that point. As this leakage is reduced the life of the carbon becomes longer.

In the new lamp illustrated in Figs. 1 and 2 a novel arrangement of the parts is made to minimize the circulation of air into and out from the inner globe. In the first place, as in some previous lamps, the negative or lower carbon holder is brought down within the globe, doing away with an opening at the bottom. The chief novelty lies in the fact that the bottle cap is made a part of a long cylinder or tube which is air tight and encloses the whole of the upper carbon. The arc enclosure thus consists of the transparent inner globe fastened tightly to the lower end of this cylinder, both carbons being entirely within the enclosure.

Another factor that tends to improve arc economy is the high temperature of the inner globe, the light emitted being dependent upon the temperature of the arc, which temperature is maintained under reduced heat dissipation with a corresponding reduction of the power consumed. As most of the heat from the arc rises and is conducted away by the metallic upper portion of the enclosing chamber, this is in the Toerring lamp simply surrounded by the series resistance so as to keep it hot.

By these means the carbon consumption is claimed to be greatly reduced, the maker guaranteeing the lamp to burn 200 hours under ordinary conditions with 12 ins. of carbon, the arc being adjusted to about 85 volts, and claiming that it has burned under the same conditions over 300 hours.

The means of trimming and adjusting the lamp will also appeal to those who use it. With the inner globe removed the upper carbon is simply pushed up through the lower carbon holder and the clutch and into the sheath which encloses and carries current to it. The negative carbon is pushed in after it and is simply broken off with plyers if it protrudes below the holder, no measurement or cutting to gage being necessary.

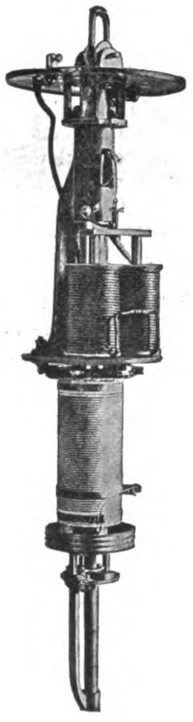

FIG. 1.—THE MECHANISM OF THE LAMP.

The brass threaded spinning which holds the inner globe to the cylinder forming the upper part of the enclosure is readily removable with the inner globe, so that the lamp may be trimmed when hot. By simply lowering the outer globe to the position shown in Fig. 2, the resistance becomes accessable.

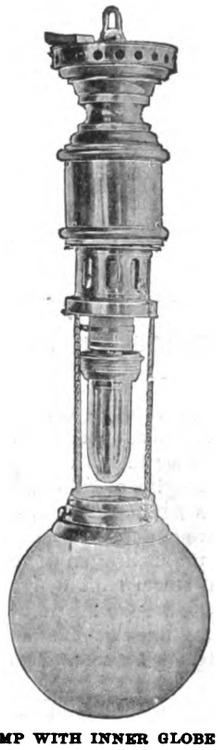

FIG 2.—LAMP WITH INNER GLOBE LOWERED.

The rheostant consists of a high resistance wire laid in a helical groove formed on the surface of a porcelain cylinder. This construction adds to the head radiating surface and permanently holds and separates each turn of the wire on a fireproof structure. The resistance is changed by clamping a strap about the cylinder, and in contact with the wire at any desired position.

The construction of the regulating mechanism is entirely of fire-proof materials. The clutch is located within the enclosing globe and operated by a double magnet, shown in Fig. 1, pulling downwardly on an armature attached to a chain running over a small pulley.

The lamp is short, measuring 26 ins. over all and weighing about 18 lbs. with the globe. It is made for 110 and 220 volt direct current circuits, a 500 volt and series lamp being in course of development.

The lamp was designed by Mr. C. J. Toerring, who has had no little experience in this line of work with various lamp manufacturers, notably the Helios Electric Company. The maker of the lamp is the C. J. Toerring Company of Philadelphia.

---

## AN IMPROVED ELECTRIC SOLDERING IRON.

After many attempts to produce an electric soldering iron that would be perfectly satisfactory in every respect, the United Electric Heating Company, Detroit, Mich., has placed upon the market the iron shown in Fig. 3.

FIG. 3.—AN ELECTRIC SOLDERING IRON.

This iron is compact and short and very light in proportion to its size, being, in fact, much lighter than the ordinary solid copper iron of the same size or intended for the same class of work. This result has been accomplished by the use of aluminum in the main body of the iron and by making the copper portion no more than a tip, instead of the long piece required to store heat in an ordinary iron.

There is no deterioration in the aluminum core, as this metal is not affected by either acid or acid fumes, or by heat, as it does not oxidize as will brass, iron or other metals. The aluminum core is a very good heat conductor and is so constructed that the heat generated is conducted to the copper tips where needed, and is prevented from being transmitted to the handle by a ventilator placed at handle end of the core. This is an important feature, as the heat generated is concentrated where needed and loss due to transmission to undesirable parts of the iron or by radiation is small, making the iron efficient. The copper tips are made detachable and interchangeable, so that any size or shape of tip may be used on one iron.

The iron attains full heat in about three minutes after the curent is turned on and is then ready for continuous use.

### A STORAGE BATTERY BOOSTER.

The Bullock Electric Manufacturing Company, Cincinnati, Ohio, has recently shipped to the La Capital Company, Buenos Ayres, S. A., a booster to be used in connection with the extensive electric railway system of this company.

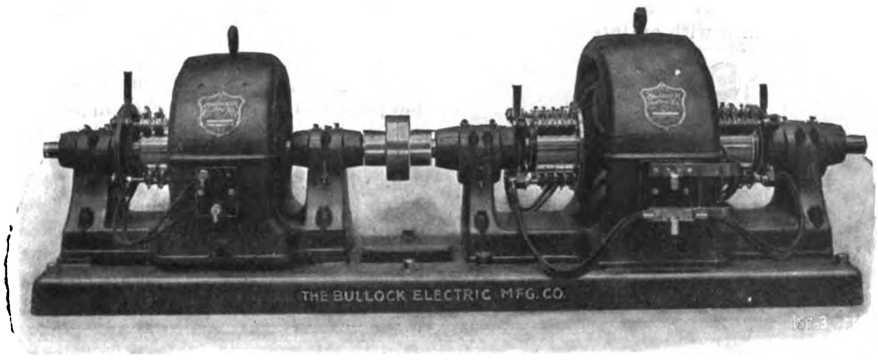

FIG. 4.—A MOTOR-DRIVEN BOOSTER FOR A RAILWAY STORAGE BATTERY.

Fig. 4 clearly shows the general features of the machine, which consists of a generator driven by a 100 h. p. motor adapted to use current from the railway feeders varying in pressure from 550 to 650 volts. At the latter pressure the speed is 1000 r. p. m.

The generator has a double commutator and is compound wound with a capacity of 1000 amperes at 60 volts or 500 amperes at 110 volts. Provision is made at the switchboard for using the shunt and series coils separately or together. The machine is equipped with a shaft oscillator, which is of the automatic magnetic type. The machines are rigidly connected by a flanged coupling and are mounted on a heavy iron sub-base, which gives accurate alignment.

This is the second booster the Bullock Electric Manufacturing Company has furnished the La Capital Company. High grade machinery is naturally selected for this far-off installation, as failure so far distant from the source of production would be disastrous to the business interests of the operating company.

---

### A LOW-PRICED MEDICAL BATTERY.

In line with its other devices for obtaining interesting electrical effects on a small scale and with low-priced apparatus the Knapp Electric & Novelty Company, New York City, has recently brought out what is called the Knapp "Shocko" medical battery, a view of which is shown in Fig. 5.

The whole arrangement consists simply of a single "elektric" dry cell mounted on a base board with a simple induction coil and fitted with a pair of handles and a combined vibrator and switch. The dry cell is fastened down by means of a sheet of metal bent around it and can be replaced by simply loosening the screws fastening this sheet down to the base board and taking out the one wire attached to the carbon terminal. The zinc shell of the battery makes contact with the sheet metal fastening without the use of any wiring.

On the sheet metal fastening is pivoted the switch, which in turn carries one contact of the vibrating make and break device. A movement of this one device closes the circuit and adjusts the contact.

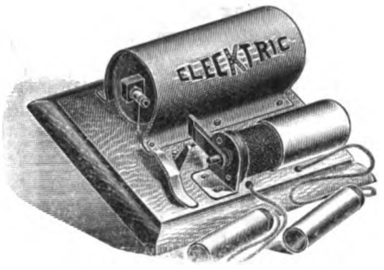

FIG. 5.—A SIMPLE INDUCTION COIL.

The coil is wound on a wooden spool and provided with a cylindrical sheet metal short-circuiting tube, which can be slipped on or off to any position to adjust the strength of the shock. A pair of hand electrodes completes the instrument.

### A DIRECT GEARED MOTOR DRIVEN PUMP.

The pumping outfit shown in Fig. 6 is especially designed for use in breweries, mines and similar places where a rugged, sturdy machine, capable of withstanding considerable abuse, dampness, etc., is desired. The complete outfit is very compactly arranged on one base plate, the double reduction gearing being arranged vertically so that the floor area is kept down to that of the plate. The motor is of the Bernard enclosed type, specially fitted for this purpose with a journal on one end of the shell. It is in line with the rotary pump, which is of the positive action type, running at about 60 or 70 r. p. m.

While the motor appears to be of very large size compared with the pump, this is due to the fact that an enclosed motor is necessarily of generous proportions in order to dissipate the heat generated by it, and the pump may act against considerable heads, requiring a large amount of power. The strength of the apparatus is apparent from the fact that in spite of the size of the motor and the great leverage it obtains by means of the double reduction gearing, the outfit is so designed that it may be stopped at any time, if fitted with a circuit breaker, by simply putting a kink in the hose attached to the delivery, the extra load thus thrown upon the motor opening the breaker without injuring any of the parts thus strained.

The manufacturer of the complete outfit is the E. G. Bernard Company, Troy, N. Y.

---

### THE ROBERTS BORING MACHINE.

The loss of time and inconvenience of erecting scaffolding for working from the top of ladders when boring holes through overhead joists are hardly realized by wiremen and contractors who have be-

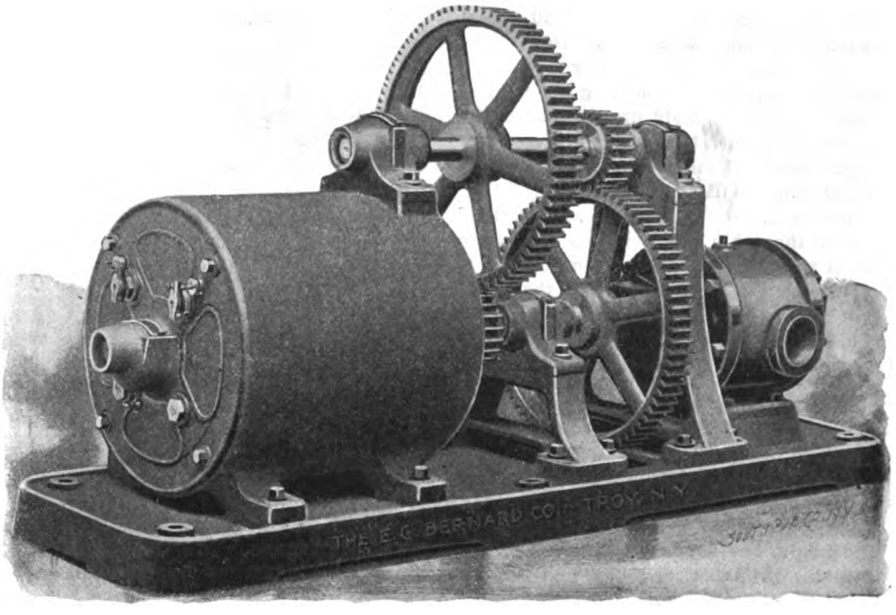

FIG. 6.—A MOTOR-DRIVEN BEER PUMP.

Digitized by Google

come habituated to such work. The time spent in getting in place is invariably more than that spent in boring the hole, and the comparative ease of working from the floor is enormous.

The apparatus shown in Fig. 7 holds a bit on the upper end of a long upright

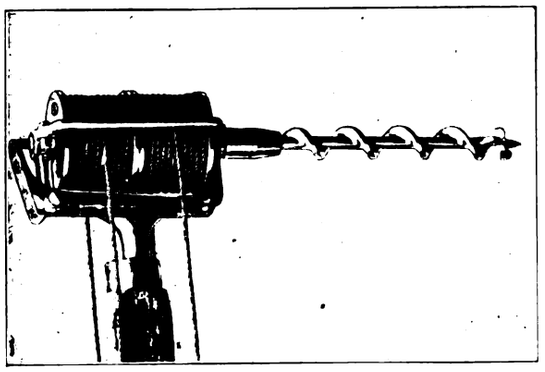

FIG. 7.—A JOIST BORING TOOL.

which may be extended from 7 to 16 ft. in length to reach ceilings between those heights. The lower end of the upright rests upon the floor, where the operator stands and turns the bit by means of a pulley carrying cables and a ratchet, which, when the cable is rewound prevents the bit from being turned out. A small chain, not shown in the cut, reverses the ratchet so that the bit may be turned out when the hole is completed.

The machine is covered by patents and made by Jas. McCrea & Company, Chicago.

### A CABLE SUPPORTING CLIP.

The improved holdfast cable clip, shown in Fig. 9, is quickly and easily applied by hand and can be readily removed from time to time for new work without impairing its holding power. The metal strap is simply drawn around the cable and passed through the hanger, the part with the hooks is then turned up, as shown in the illustration, which action takes up the slack, binds the strap tightly about the cable and prevents the latter from slipping. All parts are made of galvanized steel or zinc, so that they will not rust or in any way injure the cable. This clip is made by James S. Barron & Company, New York City.

### SOME ERICSSON TELEPHONE APPARATUS.

In spite of the extremely rapid development in this country of manufacturing houses building telephone apparatus for independent exchanges, the comparatively ancient establishment of Ericsson in Stockholm has not been distanced in the race for the latest and best and has an edvantage over its younger competitors in the experience it has gained through long years of practice.

Ericsson & Company of this country have lately imported some new lines of Ericsson apparatus, some details of which are illustrated and described below.

In Fig. 10 is shown the new Ericsson Swedish bipolar all-metal Samson receiver. A feature of this instrument is that it has a brass shell covered with a hard rubber tube. The magnet is fastened to this shell by screws near the front end and is provided with an internal arrange-

FIG. 8.—A MICROTELEPHONE WITH AN INTERCOMMUNICATING SWITCH.

ment for adjusting the distance between the poles and diaphragm, which adjustment cannot be changed after the magnet is screwed in place. The structure being entirely of metal, no further adjustment

FIG. 9.—A HOLDFAST CABLE CLIP.

is necessary. The head is made of brass, nickel plated, the metal giving the instrument much better acoustic properties than those of the comparatively dead materials, so far as sound is concerned, hard rubber

FIG. 10.—THE ERICSSON SAMSON RECEIVER.

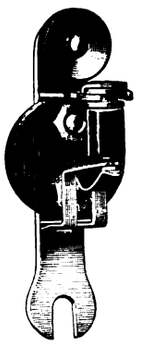

FIG. 11.—A HEAT COIL SNEAK CURRENT ARRESTER.

or its imitations. The diaphragm is nickel plated, as are the ends of the bipolar magnet, to prevent these parts from rusting.

Another detail of interest is Ericsson's Swedish lightning protector, a view of which appears in Fig. 11. This is built on the heat coil circuit breaker principle, a small coil surrounding a fuse which is attached to a button slipped under a downwardly pulling spring. In case of any sneak current the fuse is melted, the button is released and the spring flies downward, opening the circuit by an inch or more.

Another popular piece of apparatus is that shown in one form in Fig. 8. To the left is the coal-grain hand microtelephone, fitted with a hand contact in its grip, which serves in place of the hook switch in the ordinary telephone set. This hand contact is fitted with front and back needle point contacts of platinum, cutting in the bell in the normal position and the battery and induction coil when pressed by the fingers. The particular advantages of such an instrument over the ordinary form with the microphone attached to the wall or desk fixture are the facts that if by mistake it is laid down the line is not thrown out of use and the user can neither get an improper distance from the microphone, nor is he liable to turn away from it, the instrument retaining its proper position in front of the mouth, no matter whether he turns around or not. This is made up for use as either a wall or desk or interior telephone, the illustration showing the latter combination. When used on the desk the microtelephone is simply laid or hung anywhere, and no standard with hook switch and microphone is necessary.

The company also has now a swinging switchboard transmitter in addition to its breastplate transmitter formerly carried, a new transmitter arm with concealed cord and binding posts, a carbon lightning arrester and a repeating coil specially designed for what is called "duplex" working. By this use of the word "du-

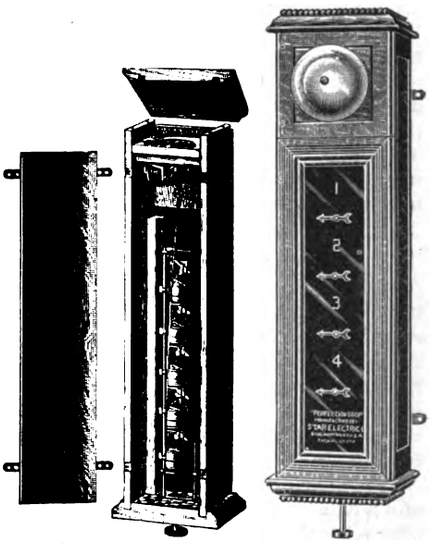

FIG. 12.—THE PERFECTION DROP ANNUNCIATOR.

plex" is meant the operation of three metallic circuits on four wires. Two of these wires are used in the usual way for one circuit and two for one other with repeating coils at the end of each. The third circuit uses the two wires of one of the other circuits for one side of its line and

Digitized by Google

the two wires of the other for the other side of its line, and is obtained by simply tapping metallically into the center turns of the line sides of the repeating coils.

The company has many other improvements and refinements, such as what is called the even balanced talking circuit, consisting of microphone, induction coil and receiver with the proper relative resistances, so as to get maximum talking effect at the receiving end.

### THE PERFECTION DROP ANNUNCIATORS.

In the ordinary annunciator the indicator is held up against the force of gravity by a trigger attached to the operating armature. In case of jolting in car, steamship and elevator service, the annunciator is frequently mechanically tripped, giving false indications, which seriously impair the reliability of the instrument.

In the annunciator shown in Fig. 12, to which the ambitious name at the head of this notice applies, the armature operates the indicator directly instead of releasing it and allowing it to be operated by some other force. The indicator is caught when in the horizontal position and held there until released by the restoring rod. The indicator is thus liable to be shaken loose only during the brief interval when it is down instead of during the comparatively long interval when it is up. In the case of a 100-drop annunciator there may be on an average one indicator down at a time and 99 in the up position, and mechanical jarring is likely to affect only the one instead of the ninety and nine.

The instrument is made by the Star Electric Company, Binghamton, N. Y.

### A BOILER PLANT WITH A SMALL REPAIR ACCOUNT.

Quite a remarkable instance of low cost of maintenance of steam boilers recently came to light when the Wagner Palace Car Company decided to make some changes in the boiler plant of its shops at East Buffalo, N. Y. The original equipment, installed over 9 years ago, consisted of five 150 h. p. porcupine boilers, built by the Hazelton Boiler Company, New York City. These were set in the standard brick work commonly used at that time. When the changes came up it was decided to refit them with the Hazelton Company's new type of steel casing or jacket, the battery of boilers after this change having the appearance shown in Fig. 13.

Not a dollar has ever been expended upon them in repairs and when the change was made last Spring the boilers were found in excellent condition. The new steel casings are made so that the fire-brick linings of the furnace can be removed and new fire-brick lining placed without disturbing the upper sections of jacket. The tubes can be removed at any time from the inside of main cylinder of boiler and new tubes inserted on the inside. The sections are provided with doors as the illustration shows, through which a hose may be inserted and a jet of steam or compressed air blown around the tubes to clean them of soot.

The interior construction of the boiler is shown by the vertical section, Fig. 14. From this it will be seen that the heating surfaces consist of a number of straight horizontal tubes radiating from a central vertical cylindrical shell, giving the straightest course for the flue gases from the fire to the stack and yet a course where they are continually compelled to eddy about the heating surfaces.

The circulation of steam is maintained in the upper tubes and a certain amount of drying or of superheating is obtained by taking the steam from an interior drum fitted with small tubes drawing steam from the ends of the larger tubes, as the illustration shows.

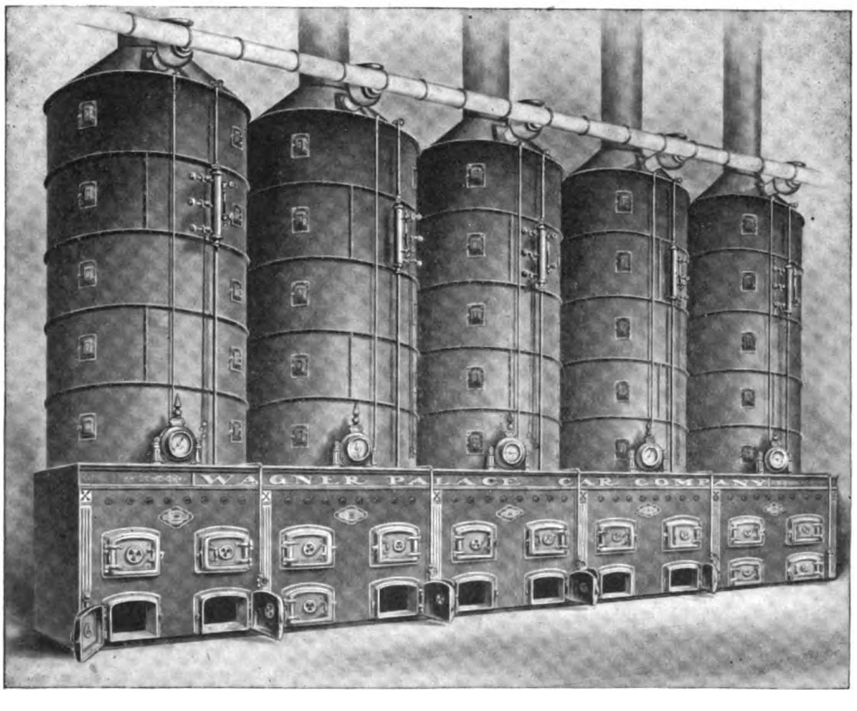

FIG. 13.—THE BOILER PLANT AT THE WAGNER PALACE CAR WORKS.

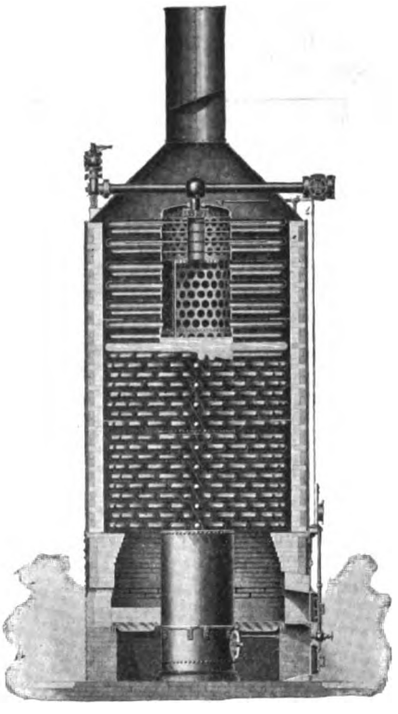

FIG. 14.—SECTION OF PORCUPINE BOILER.

The instance given above of low cost of repairs is in line with other experience with the same boilers, the company claiming that boilers of this make have been in use for 19 years and are still running, on which no repairs have ever been made. On the entire output for 20 years the company claims that less than ¾ of 1 per cent of the first cost has been expended for repairs and that 90 per cent of this amount has been on the boilers of one concern, which is crowding its equipment far beyond the rated horse-power for which the boilers were constructed, the officials of this concern considering it more economically to occasionally renew the tubes than to put in more boilers.

### THE SINGLE VALVE TANDEM COMPOUND TYPE OF THE HARRISBURG SYSTEM OF ENGINES.

Under certain conditions it pays to compound high speed single valve engines with fly wheel governors. These conditions are: High cost of coal, intelligent attendance, boiler pressures from 110 to 150 lbs. and engine capacities above 75 h. p. The use of a compound in place of a simple engine, where most of these conditions exist, effects a saving of fuel which warrants the additional cost of the more elaborate engine. Under average conditions of load and size the steam consumption of simple, high speed, single valve engines runs from 30 to 35 lbs. per h. p.

Digitized by Google

hour, while that of similar compound engines is only from 22 to 26 lbs., or even from 18 to 20 lbs. with condensing apparatus.

The Harrisburg Foundry & Machine Works, Harrisburg, Pa., manufactures among the various types of its complete system both simple and tandem compound, horizontal, high speed, single valve engines, and advocates the use of the latter under the conditions which, as outlined above, warrant the compound type. The construction of this engine is shown in Fig. 15. The low pressure cylinder is placed next to the engine frame, this arrangement giving the outer and smaller cylinder a more substantial attachment to the frame than the smaller cylinder would give the larger if the parts were interchanged. The connection between the two cylinders is itself cylindrical in shape and larger than the low pressure cylinder head, so that the latter may be unbolted and slipped back along the piston rod to allow the adjustment of the packing rings of the low pressure piston without taking down the high pressure cylinder and its piping. The connection is cut away at the two sides to permit this easy access to the head of the low pressure cylinder as well as to the two stuffing boxes. The high pressure cylinder is supported by means of the connection between the two cylinders, which connection rests upon the extended sub-base casting. The connection rests upon the sub-base through a tongue and groove, and is fastened down through slotted bolt holes. This arrangement allows horizontal motion in the direction of the piston rod, thus taking up thermal expansion and contraction without strains.

The receiver and steam passage way between the high and low pressure cylinders is a flanged casting, hung beneath the steam chests. In the smaller sizes both the high and low pressure valves are operated by one eccentric actuated by the centrally balanced centrifugal inertia governor, the accompanying illustration representing an engine with this arrangement. The larger sizes are, however, built with two separate eccentrics, one fixed and driving the low pressure valve but fitted so that the cut-off may be set by hand to properly distribute the work between the two cylinders for the average load that the engine is called upon to perform. The high pressure valve is then alone driven by the governor eccentric.

Further valve adjustment is obtained by the construction of the heads of the piston valves which are adjustable as regards both lead and lap, to suit any changed conditions of working, such as a new boiler pressure or the removal or addition of condensing apparatus. By these means one engine may be adjusted without new parts to give satisfactory working and the highest economy under various requirements.

These engines may be and are made in the center crank, self-oiling style of the Ideal engine, which is another and older type of the system of engines made at the same works.

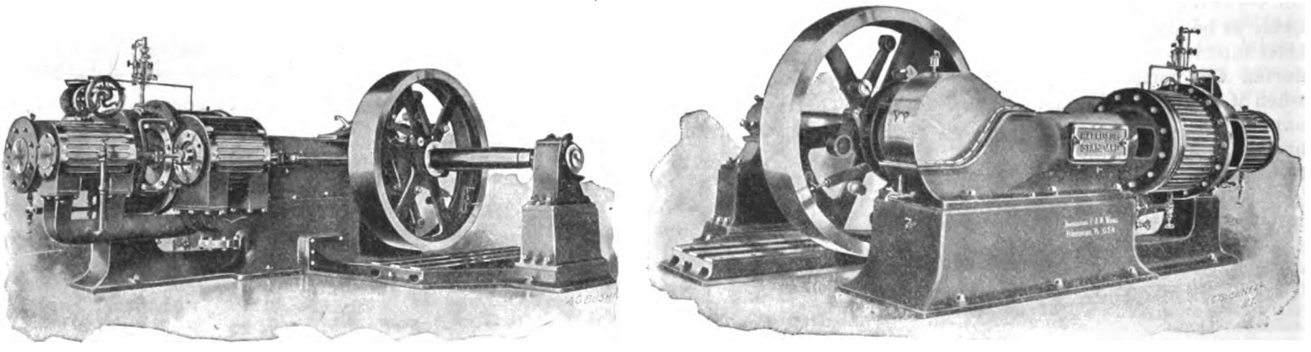

FIG. 15.—VIEWS OF THE HARRISBURG SINGLE VALVE TANDEM COMPOUND ENGINE FROM BOTH SIDES.

## NEW BOOKS.

Practical Electricity. By J. C. Lincoln. Cleveland. Pocket Edition. The Cleveland Armature Works. 286 pages. Illustrated. Price $2.

This work is the outcome of a series of lectures on the design of dynamos and motors, embodying the results of daily shop practice. The work as now published is intended for those who have some practical knowledge of electricity and desire to obtain a further insight into the calculation of circuits and the methods of constructing and wiring dynamos and other electrical machinery. Each chapter is followed by a number of questions, the answering of which will test the reader's comprehension of the previous text and tend to fix the ideas in his mind. Correct answers to the questions are to be found at the end of the book. The work is extremely simple in style and correspondingly elementary in character.

The Elements of Physics. By Henry Crew. New York; The Macmillan Company; 342 pages; illustrated. Price, $1.10.

This work, which was designed especially for use as a text book in high schools, is written in unusually clear and simple style. While elementary mathematics and precise terms are, to a certain extent, necessary, they are avoided as far as possible in favor of the plainest and simplest of English. The various physical laws are explained in a simple, practical manner, which makes each division of the book readable and interesting. What appears to be a hobby of the author and is followed through the work, is the recognition of the intimate relation of all departments of physics and the unity of the laws of nature which have been discovered therein. The student is led through the various departments of mechanics, sound, heat, electricity and light, with this idea in mind, the arguments of one department being based upon the conclusions of those preceding, and the deductions explained by analogies thereto.

## LEGAL NOTES.

A. L. IDE & SONS, Springfield, Ill., have brought suit in the United States Circuit Court, St. Louis, Mo., against users of Chuse engines, praying for an injunction against the infringement of patents on lubricating devices.

THE GENERAL ELECTRIC TROLLEY CONTACT-SPRING CASE. — The General Electric Company has obtained in the United States Circuit Court, District of New Jersey, an opinion of Judge Kirkpatrick sustaining the claims of Patent No. 412,155, granted to Albert Anderson on trolley contact springs. The opinion was delivered in the case against the Rahway Electric Light & Power Company and was filed August 1st, 1899. The patent covers the use of contact springs within the trolley harp and bearing on the ends of the hub of the trolley wheel. The defense was lack of patentable novelty in view of the prior art, which was completely set aside in the Judge's opinion.

THE WESTERN TELEPHONE CONSTRUCTION COMPANY, Chicago, has been granted a favorable decision by Judge Bretano of the Superior Court of Cook County, in a suit brought by Madison B. Kennedy, a stockholder of the company, asking for a receivership, which case has been under litigation for some two years past. The allegations in this case and the rumors which have spread through the trade on account of them have been a serious trial to the Western Telephone Construction Company, and particularly to its president, Mr. J. E. Keelyn. The Judge's opinion entirely clears them aside and comments strongly upon the lack of a cause for the charges. The company states that of all the hundred and more law suits in which it has been either complainant or defendant during the last six years, it has invariably been victorious.

THE MULTI-GLAZED INSULATOR INTERFERENCE.—Mr. Fred M. Locke, Victor, N. Y., has announced that the insulator comprising two or more shells of porcelain nested and fused together with glaze has been decided by the examiner in the Patent Office to be the invention of Mr. Locke. Mr. Locke filed his application for letters patent in February, 1897, and, in August of the same year, Mr. Boch, of the R. Thomas & Sons Co., of East Liverpool, Ohio, filed an application for the same thing. An interference was declared between the two applications and also between Mr. Locke and a patent granted March 8, 1898, to Mr. Boch, which comprises substantially the same invention, except that the parts were fused together with extra glaze. Interference proceedings have been pending since September, 1897, and a few weeks ago the Patent Office decided that Mr. Locke had proved "that Locke was the first to conceive, disclose and reduce to practice the invention in issue; judgment of priority is awarded to Fred M. Locke."

In the second interference with the patent of Mr. Boch the examiner held that "whichever party is entitled to prevail as to the issue in one interference is equally entitled to prevail in the other; the fact in this instance, the burden of proof is upon Locke and that Boch is the patentee is of no moment, for to the examiner's mind Locke has established his claims of priority beyond a reasonable doubt. Judgment of priority of invention is awarded to Fred M. Locke."

## PERSONALS.

MR. W. J. JOHNSTON, until recently proprietor of the "Electrical World," sailed August 17th from San Francisco on a trip around the world. Mr. Johnston will spend some time in the Hawaiian Islands, Japan, China, India, Egypt, etc.

MR. ARTHUR WARREN, manager of the advertising department of the Westinghouse Electric & Manufacturing Company, returned from Europe on Aug. 5. While on the other side he was busily engaged in the exploitation of the new Westinghouse manufacturing company in England.

MR. GEORGE A. THOMPSON, who was formerly connected with the Short Electric Railway Company, the Forest City Electric Company and other well known Western concerns, has been appointed Eastern representative of the Adams-Bagnall Electric Company, the well known arc lamp manufacturers, in place of Mr. C. W. Phipps, resigned, and is now established at the company's New York office, 222 Havemeyer Building.

MR. J. H. HALLBERG, who has been for the last three years electrician for the Standard Thermometer & Electric Company, has resigned this position to accept a similar one with the arc lamp department of the General Incandescent Arc Light Company, New York City. During Mr. Hallberg's connection with the former company he designed and perfected the Midget enclosed arc lamps. His work with the new company will be in the line of arc light designing and perfecting. Mr. Hallberg takes charge of his new duties on or about September 1st.

MR. G. W. HUBLEY, Louisville, Kentucky, now represents as sole agent for that state, the American Electric Vehicle Company of Chicago, and hopes soon to introduce into his territory many vehicles of this company's make. His duties in this connection will not interfere with his position as Superintendent for the Louisville Electric Light Company. The example of Mr. Hubley in this connection would be a good one for other central station superintendents to follow, work of this kind being such that it can be done without interfering with their regular duties and giving every prospect of proving profitable both for the individual undertaking it and the central station.

MR. ISAAC L. RICE resigned on August 17th his position as president of the Electric Storage Battery Company. First Vice President Geo. H. Day was elected his successor. Mr. Rice gives as a reason for his resignation lack of time to attend to the affairs of the company. He remains a member of the board of directors and retains his financial interest. Mr. Rice wil remain at the head the Electric Vehicle Company and the Siemens & Halske Company. Mr. Day, who succeeds Mr. Rice, is the Vice-President of the Pope Manufacturing Company and prominently connected with the Columbia & Electric Vehicle Company.

MR. J. J. SWANN, until recently Associate Editor of "Engineering News," and in charge of the articles on electrical subjects appearing in that periodical, has accepted a position with the Ingersoll-Sergeant Drill Company. Mr. Swann will have complete charge of this company's exhibit at the coming international exhibition in Paris, and in that capacity will spend the year 1900 in the French capital. Mr. Swann's wide knowledge of electrical and mechanical engineering gained in his editorial work will be to his advantage in his new field, his acquaintance with electrical engineering and some of its limitations being of particular value in the development of the general applications of compressed air, now being aggressively advanced by the Ingersoll-Sergeant Company.

## TRADE PUBLICATIONS.

THE GOLD CAR HEATING COMPANY, New York and Chicago, has published its catalogue of 1899 and 1900, covering all its systems of car heating, including the electrical.

STEAM WITH SOFT COAL WITHOUT SMOKE is the title of a new 50-page illustrated circular issued by the Murphy Iron Works, Detroit, Mich., sole manufacturers of the celebrated Murphy automatic smokeless (stoker) furnace.

THE MAINTENANCE COMPANY, New York City, is circulating to its friends and the trade generally a convenient glass paper weight, covering an attractive illustration pointing out the purpose and character of the company's work.

THE HARRISON SAFETY BOILER WORKS, Philadelphia, Pa., have issued a treatise on feed water heaters and steam separators, setting out the meritorious points of these devices in general, of open heaters in particular, and of Cochrane heaters and oil separtors in detail.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., have published a general circular on their work as well as notes which they are now circulating calling attention to special privileges which are extended to all who enroll in the schools before October 1st, 1899. The special privileges consist of reduced rates on a complete set of drawing instruments.

THOMPSON, SON & COMPANY, New York City, have recently published a price list of second-hand electrical apparatus which they now have on hand. The line is a very elaborate one, showing the magnitude of the business the firm is now carrying on. The list contains a large amount of 110 volt, 220 volt and 500 volt direct current machinery as well as arc dynamos, transformers, open and enclosed arc lamps, etc.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, Ohio, has published under date of August, '99, a bulletin of its engine type generators. The new bulletin describes and illustrates the well known features of this type of machine, viz., the cast yoke with bolted laminated field poles and separately wound series and shunt field spools, the brush holder ring carried on three rollers from the yoke ring, the radial brushes, etc.

THE CUTTER ELECTRICAL & MANUFACTURING COMPANY, Philadelphia, has brought out a small pamphlet entitled "Indications," containing the records of a number of tests with I. T. E. circuit breakers carried out some by Prof. W. M. Stine of the Armour Institute, and some by Wm. McDevitt, inspector of the Philadelphia Board of Fire Underwriters. In addition to these tests, which show up very favorably for I. T. E. breakers, the pamphlet contains letters of recommendation from other fire and wire department officials and large consumers. The tests described and the tables given are of no little interest to those in doubt between fuses and circuit breakers.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburgh, Pa., has brought out a new catalogue of the Westinghouse, Junior, engine. The new catalogue explains in the clear and well illustrated style of Westinghouse catalogues, the meritorious points of the engine. One of these is the extreme simplicity of the crank shaft, in which there is no center bearing inside the case to give trouble, the shaft consisting of a billet of open hearth steel bent to the proper S shape between a set of dies. Another good point is the modification of the inerta governor so that it may be run in either direction by simply changing over the tension spring from one side of the weighted arm to the other.

THE B. F. STURTEVANT COMPANY, Boston, has recently published an illustrated catalogue of Sturtevant engines for electric light plants and general high-grade work, as well as two bulletins, one on the Sturtevant 8-pole motors and generators described in the August issue of the American Electrician, and the other on the Sturtevant motor driven fans. Sturtevant generating sets, consisting of enclosed high speed, two-crank engines, compactly arranged with a generator on one bed plate, while specially designed for marine service, are admirably adapted to isolated plant work where economy of space is a consideration. The Sturtevant ventilating fans are also of value in isolated plants, especially in office buildings and similar locations where forced ventilation is necessary.

THE OKONITE COMPANY, LTD., New York City, is circulating a very complete electric wire computer designed by Mr. William Cox. The computer is mechanical in character on the principle of the slide rule, made of cardboard in a circular disk or wheel form and bound in neat covers. By turning the disk until the required drop in potential in volts of one scale meets the required current in amperes of another scale, the required circular mils as well as the size of the wire on the B. & S. gage can be found, practically opposite the number representing the length of the circuit in feet. Similarly any three of the four factors involved in the calculation being known, the other can be found. The computer is of great convenience where much calculation of the proper size of wire for a given drop or of the drop under given conditions must be made.

## BUSINESS NEWS.

THE STIRLING COMPANY is making extensive additions to its boiler building plant at Barberton, Ohio.

THE MOUND TOOL & SCRAPER COMPANY, St. Louis, Mo., announces that it has recently shipped 12 sets of scraping tools to Honolulu.

THE SIEMENS & HALSKE ELECTRIC COMPANY OF AMERICA announces that it has removed its New York office to rooms 319 and 320 of the Havemeyer Building.

THE ELECTRIC STORAGE BATTERY COMPANY has removed its New York office from 20 Broad Street to the 15th floor of the American Surety Building, 100 Broadway.

Digitized by Google

THE CLAYTON & LAMBERT MANUFACTURING COMPANY anounces that it has moved from Ypsilanti to its new factory in Detroit, Michigan, where it has superior facilities for the manufacture of torches, blow pots, etc.

THE PACKARD ELECTRIC COMPANY, Warren, Ohio, manufacturer of incandescent lamps and transformers, announces that Messrs. Mayer & Englund of 10 S. 10th St., Philadelphia, Pa., have taken the agency for its incandescent lamps for street railway use.

THE ANNUAL CLAM BAKE OF THE AMERICAN ELECTRICAL WORKS will be held on September 9th at the Pomham Club, Providence, R. I. Mr. Eugene F. Phillips has sent out a novelty in the way of invitations, which are stamped on thin copper sheets.

MR. GEORGE W. LORD, Philadelphia, the manufacturer of Lord's boiler cleansing compounds, reports that he was never busier since he has been in business than at present. He recently shipped to Brazil 10 tons of his boiler compounds in response to the third order from the same source.

THE WESTERN ELECTRIC COMPANY will erect a new ten-story factory in New York City. Plans have been submitted to the Building Department calling for a brick and terracotta structure on a plot 105 by 140. The new building will cost, according to the present estimate, $450,000.

MR. SEARS B. CONDIT, JR., has severed his connection with the Chase-Shawmut Company and has opened an office at 63 Oliver Street, Boston. He will do general repair work and act as manufacturers' agent for a number of good specialties which he already has, and will add others to his line later.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., has just received an order from the Hollingsworth & Whitney Company, Waterville, Maine, for the entire engine equipment of its new mill, consisting of two special 300-h.p. double engines and a 125-h.p. engine, and also a complete 75-k.w. electric generating plant.

THE E. P. ALLIS COMPANY, Milwaukee, has made another large sale of Allis-Corliss engines for use in Great Britain. Six engines aggregating 15,000 h. p. have been ordered for the Municipal system of street railways in Glasgow, Scotland. These engines will be coupled to generators built by the General Electric Company.

THE NEW EXCELSIOR DRY BATTERY COMPANY has removed from Mount Vernon, N. Y., to 661-663 Hudson Street, New York City, which location is better adapted to the receipt of raw materials, the finding of suitable labor and the prompt shipment of goods. The change will enable the company to more promptly meet hurry orders.

W. T. PRINGLE & CO., Philadelphia, are now well equipped to turn out switches, switchboards and panel boards, for which they have already established a reputation. Their switches and switchboards meet with the approval of the fire underwriters, and Mr. Pringle announces that he has a large stock on hand ready to supply immediate demands.

CHARLES WIRT & CO., Philadelphia, report that they are extremely busy, largely with dimmer orders. They announce a new interlocking arrangement for theater dimmers, intended to render the operation of these devices thoroughly certain, permitting of quick manipulation and particularly designed to avoid error or confusion even if operated in the dark.

THE BABCOCK & WILCOX COMPANY will, it is rumored, establish new and extensive works at Bergen Point, N. J., on the shore of the Kill-von-Kull. The purchase price of the land is said to be in the neighborhood of $300,000, and the cost of the buildings proposed for erection thereon $1,000,000, which buildings will give employment to more than 1,000 men.

THE GOLD CAR HEATING COMPANY and the Gold Street Car Heating Company, New York City, report that the number of orders which they have taken during the past few months are of such magnitude as to surpass all former records of the companies. Prominent among these orders is one from the Boston Elevated Railway Company, for electric heaters for its one hundred new cars.

MR. ELMER G. WILLYOUNG, New York City, states that all orders for Willyoung instruments and other electrical testing apparatus should be sent direct to him instead of to Messrs. Foote, Pierson & Co., who will simply manufacture Willyoung apparatus as noted in the last issue of the American Electrician. While to all intents and purposes Messrs. Foote, Pierson & Co. and Mr. Willyoung are one concern, the former will be manufacturers for the latter and the latter will be the designer and seller for the former.

A NEW ELECTRICAL MANUFACTURING COMPANY.—The Scott-Janney Electric Company, Philadelphia, was recently incorporated at Trenton, N. J., with a capital of $30,000,000, and, it is stated, will erect a large plant in Philadelphia at once. Among the incorporators are Mr. Gordon J. Scott, Mr. W. S. Janney and others in the past interested in the old Scott & Janney Electric Manufacturing Company. The new company will make a general line of apparatus in competition with the Westinghouse and General Electric Companies.

EDWARD S. HALSEY, 88 State Street, Chicago, Ill., announces that he is just about ready to fill orders for the maximum recording attachment for integrating meters, which attachment was recently described in these columns. In addition to this device, which already promises to meet with quite a demand, Mr. Halsey is at work on others, one a direct current motor meter without a commutator, described in the August issue of the American Electrician, and another, a disappearing figure recording dial. For the latter there should be a great demand, as recording dials of the type now commonly used are practically unreadable to the layman, while with disappearing figure mechanisms, such as are used in cyclometers, no one who can read figures can make a mistake. Mr. Halsey now has ready for distribution a circular describing the construction and advantages of the maximum recording attachment mentioned above.

CORRESPONDENCE SCHOOL TEXT BOOKS.—The question has been raised in educational circles whether the modern and practical methods of instruction used in correspondence schools will not soon bring about decided changes in the same direction in the methods of the institutions of technical learning, and make necessary a complete revision of most of the text books now in use. The ordinary text book takes a great deal for granted and leaves the elaborate discussion of difficult points for the teacher to explain. The correspondence school, having no teacher at the pupil's elbow to fill in the long explanations, prepares text books with the idea of making everything clear and plain to the student at first sight. The text books on all the subjects taught in The United Correspondence Schools, New York City, are written with constant attention to this point. Years have been spent in their preparation and revision. Then, again, each phenomenon explained is brought forcibly home to the practical man by the mention of its practical bearing so that he constantly recognizes in the text answers to questions that have often puzzled him. This maintains his interest much more than does the development of an elaborate theory apparently unrelated to his business or professional work. The great usefulness of these clear and concise works of The United Correspondence Schools has been more fully demonstrated, perhaps, in the electrical engineering courses than in any other department of the schools. Results have been obtained and are constantly being obtained with students in these schools which must be attributed largely to the wonderful clearness and accuracy of the text books in use, which give the pupil minimum chance to obtain mistaken ideas. The Institute for Home Study of Engineering and the Correspondence School of Technology of Cleveland were recently bought outright and incorporated with The United Correspondence Schools, and their pupils now receive the benefit of the latter school's text books.

THE WESTERN ELECTRICAL SUPPLY COMPANY, St. Louis, Mo., is just putting on the market its latest improved 1900 phone,

# A COMMUTATOR NECESSITY.

**For Sale by all Supply Houses.**

**Upon receipt of this coupon we will send FREE, sample stick.**

which has many new and novel features, among which is its transmitter, which is entirely moisture and damp-proof. It is claimed that this transmitter will out-talk any on the market, and cannot pack. The transmitter proper can be removed and replaced in a moment. The telephone department of the company has issued a pamphlet, describing some of the latest things in this line and entitled "A few ringers."

MURPHY AUTOMATIC SMOKELESS FURNACES are being installed under 5,000 h. p. of B. & W. water tube boilers in the Northwestern Elevated Railway power station, Chicago, making the fourth large power station of the "Yerkes" system having the boilers equipped with these furnaces by the Murphy Iron Works, Detroit, Mich. Murphy furnaces have also been sold to the extent of 1,600 h. p. to the Allegheny Company Light & Power Company, Pittsburg, making the third order and a total of twenty furnaces for that power station.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, Ohio, has received so many English orders recently that it has necessitated the sending of Mr. B. W. Spellmire, the company's engineer of tests, to the London headquarters of the company. Mr. Spellmire will superintend the installation of Bullock machines in the territory mentioned, the first installation being in the large printing establishments of Cassell & Co., London; the Nottingham Guardian, Nottingham; Birmingham Daily Post, Birmingham; Manchester Evening Chronicle, Manchester, and the Belfast Evening News, Belfast.

THE BABCOCK & WILCOX COMPANY has sold to the Manhattan Elevated Railway Company, New York City, the boilers required for its new electric generating plant, which will furnish electric current for operating its entire elevated railway system in New York City. The boiler equipment will consist of sixty-four 520 h.p. Babcock & Wilcox all wrought steel boilers, capable of carrying a working pressure of 200 lbs. per square inch. The boilers will be fitted with Roney automatic stokers, manufactured by Westinghouse, Church Kerr & Co. This is the largest single order ever placed for stationary boilers.

THE RIDGWAY DYNAMO & ENGINE COMPANY, Ridgway, Pa., has received recently, besides other business, orders for three 75-h.p. tandem compound McEwen engines direct connected to three 50-k.w. Thompson-Ryan generators, purchased by the Treasury Department for lighting the United States Court House and Post Office building at Cincinnati, O.; two 250-h.p. engines direct connected to two 150-k.w. generators for the Berwind-White Coal Mining Company, Philadelphia, Pa., for their mining operations at Windber, Pa. This will make a total of fourteen engines and ten generators of this make installed by these same people at Windber, Pa., within the last two years.

SPANISH-AMERICAN WAR PANORAMA AND GREATER AMERICA is one of the war books which is likely to be in continuous demand. It is a panoramic record of the triumph of Yankee Doodle. The eagle flaps his wings on every page, and "Old Glory" waves around and above every scene. Prominent officers connected with the war are here portrayed, as well as many of the "men behind the guns." The album is 5½x8 inches, weighs 12 ounces, printed on finest coated paper. Mr. Warren J. Lynch, general passenger and ticket agent "Big Four Route," Cincinnati, O., will mail a copy to any address in the United States, Canada or Mexico, for 12 cents to cover postage and packing.

THE WESTERN ELECTRICAL SUPPLY COMPANY, St. Louis, Mo., general selling agent for the Adams-Bagnall enclosed arc lamps, is gratified over the recent lamp tests conducted by the electrical department of the Ohio State University. After a series of tests as to efficiency, mechanical construction, general design and adaptability, the company states that the Adams-Bagnall lamp showed itself to be ahead of all others, making the general average of 97.1% on a basis of 100 of desirable points. The remaining seven of those in competition showed as follows, 87%, 88.7%, 92.6%, 93.3%, 89%, 92% and 90.2%. These tests were conducted not only for scientific purposes, but it was the intention of the University to purchase quite a number of the lamps which proved themselves the best. The contract was awarded to the Adams-Bagnall lamp.

THE VALUE OF CLING-SURFACE.—One of the most valuable points relating to the use of belts is not often fully realized, or, at best, not emphasized: this is the fact that the more belt surface there is running in contact with the pulley the greater is the power that may be transmitted by the belt. In running a belt tight only about half of the pulley surface is in contact with the belt, while if a belt can be made to run slack without slipping it can be made to embrace a greater arc and more power may be carried. The Cling-Surface Manufacturing Company of Buffalo, N. Y., reports that it is adding scores of belts every week to the number already running slack through the use of Cling-Surface, and of the daily letters received acknowledging this, one from Alhambra, Cal., says "after thoroughly testing Cling-Surface I find that I can run with a slack belt and get more power by far than I could with a tight belt before using Cling-Surface."

fuel economizer, have recently received the following orders: For the Hollingsworth & Whitney Company, Waterville, Me., two large economizers, two induced draft fans with 14 ft. wheels direct connected to engines, together with about 150,000 pounds of steel smoke breechings, dampers, stacks, etc; Lukens Iron & Steel Company, Coatesville, Pa., two economizers, two induced draft fans with 12 ft. wheels and direct connected engines, also about 80,000 pounds of smoke breechings, dampers and connections; Weston Electrical Instrument Company, Newark, N. J., for the power house of its new works at Waverly, two economizers with metallic casing, connections, etc.; Vacuum Oil Company, Rochester, N. Y., third order, one economizer for utilizing waste heat from oil stills; Monterey Electric Light Company, Monterey, Mexico, one economizer complete with metallic casing, induced draft fans, etc. The York Light, Heat & Power Company, York, Pa., has closed a contract with Broomell, Schmidt & Co., Ltd., for two 250 h. p. American water tube boilers, complete with induced draft fans, settings, etc.

THE MICHIGAN ELECTRIC COMPANY, Detroit, Mich., reports that it has so far this year been crowded with work to its utmost capacity. Besides the ordinary small work, some interesting orders were as follows: For the City Hall in Detroit this company was given the contract to place permanent decorative lighting (including over 1,000 incandescent lights), and for the front of the City Hall a permanent adjustable metal frame for supporting electric signs, to welcome the different conventions (numbering over fifty) which are scheduled to meet in Detroit this year. This contract includes the furnishing of about 150 two, three and four foot metal illuminated letters for this use. There have already been in place fifteen or twenty of these convention signs, including a special "C. E." about 15 feet in diameter and weighing over a ton, which was used at the time of the Christian Endeavor convention. The company was also given a contract for furnishing and installing all electric work at the Christian Endeavor grounds (covering three city squares) which lighting included 70 arc and nearly 1,000 incandescent lights. The company now has in hand the exclusive contract for all electrical work at the Elks' Street Fair and Midway Exhibition to be given in Detroit from August 21st to September 2d, inclusive, for which there will be required 2,000 or more incandescent lights, 40 or 50 arcs, and probably several searchlights, as well as an electric fountain. This decorative lighting for the Elks' Fair will be one of the handsomest exhibitions of this class of lighting, for a two weeks' exhibition, that the country has ever seen.

ELECTRICAL NOVELTIES of the dry battery and miniature lamp order from the scarf pin of the last generation to a walking cane with a lamp concealed in its head for finding keyholes and similar purposes are generally considered unreliable toys not worthy the consideration of the engineer. That such a prominent concern as the Western Electric Company has taken up the manufacture of such devices is an indication that the dry battery, the essential feature of such novelties, has been improved to a point where the devices become of real practical use. The battery used is that named by the company the "Ever Ready" dry battery, the cells of which are ingeniously arranged with contacts on their ends so that several cells may be slipped one after another into a cylindrical shell and make suitable contacts. The lamps used are also an improvement on previous devices of the same nature, obtaining a much higher economy which gives longer life and greater light with the same battery. A carbon filament is not used, the emissive material being of metal, and the lamps are very perfectly exhausted in order to obtain a small convection of heat across the short space between the filament and the bulb. The novelties include surgical and dental lamps, bicycle lamps, night lights, electric candles, etc., one of interest and value being an electric gas lighter, in which the battery raises to a high temperature a platinum gauze which lights the gas in place of the spark and magneto commonly used. This gas lighter may be fitted with a miniature lamp supplied by the same battery, by means of which the gas fixture may be found without fumbling around in the dark.

# THE DOUBLE-CURRENT GENERATORS AND POLYPHASE APPARATUS OF THE CHICAGO EDISON COMPANY.

**A Complete Equipment for the Simultaneous Generation of Alternating and Direct Currents in the Same Machines, or the Conversion of Direct to Alternating Currents for High-Tension Transmission Purposes and Reconversion.**

BY HOMER E. NIESZ.

When the Edison lighting companies found that the low tension of their direct-current systems of distribution limited the area which one station could supply and required for larger areas a number of stations with a poorer economy than that of the equivalent single generating plant, they accepted as a valuable ally their erstwhile enemy—the alternating-current system. The rapid development of polyphase apparatus and particularly of rotary converters opened up a line of possibilities in central station consolidation and electrical co-operation that live engineers were quick to grasp, when it had been demonstrated by a plucky few how great were the advantages of transmission and distribution by this new system. Among the first to advocate, and the pioneer to adopt the system of transmitting alternating three-phase currents at a high potential to a sub-station, changing the power through step-down transformers and rotary converters and distributing it by

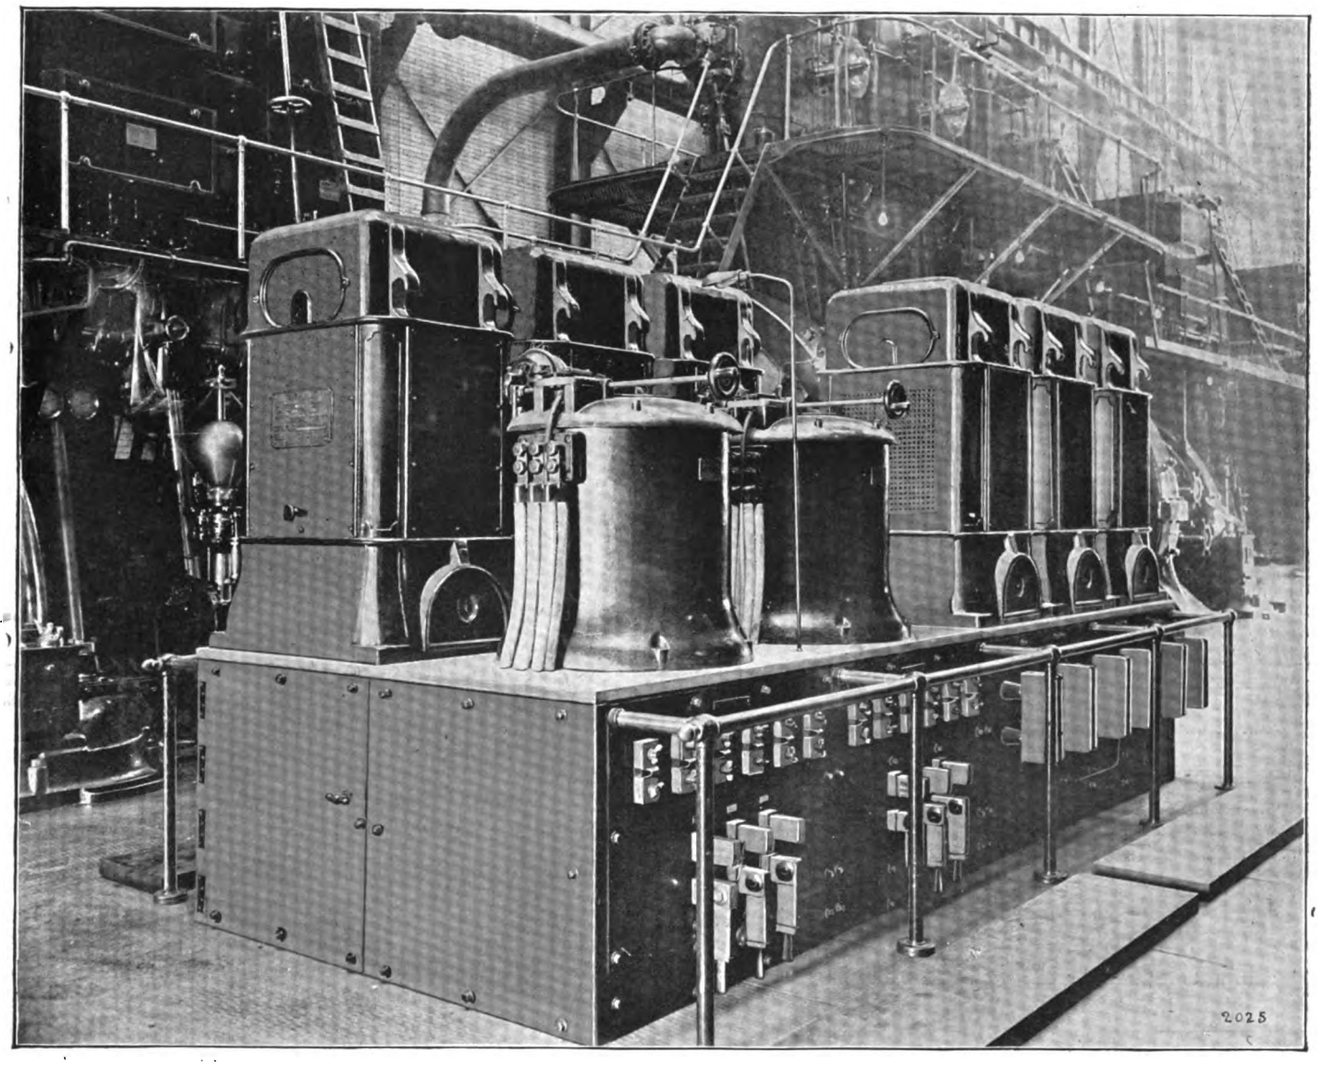

FIG. 1.—THE INDUCTION REGULATORS AND STEP-UP TRANSFORMERS FOR TWO DOUBLE-CURRENT GENERATING UNITS IN THE HARRISON STREET STATION OF THE CHICAGO EDISON COMPANY.

Digitized by Google

means of a three-wire direct-current network, was the Chicago Edison Company, whose installation is the subject of this article.

Early in 1893 the possibility of such an installation was first seriously discussed and considered by the electrical engineer of the company, but it was then too early to put his ideas into execution, because the manufacturers had not yet developed suitable apparatus; and it was not until the spring of 1897 that the long cherished and strongly advocated plans were realized by the installation in the Harrison Street station of a 250-kw. converse rotary converter, that is, a machine absorbing direct and delivering alternating power. This rotary is driven by direct current taken from the + and — bus bars of the switchboard, though it was originally designed as a double-current belt driven generator, the first of its kind ever built.

From three collector rings at the end of the machine opposite the commutator three-phase currents are taken and conducted to air-blast transformers which raise the pressure to 4500 volts for transmission over 3½ miles of cable to a sub-station located at 27th Street and Wabash Avenue, where, by means of step-down transformers, the voltage is reduced and the power is transformed by means of two 100-kw. rotary converters into direct current feeding into the three-wire network of that district.

The success of this installation was so pronounced that it was immediately decided to enlarge it the following year. It then became expedient to build a double-current generator, so that the same unit could be used either on the direct-current downtown system or the three-phase transmission line independently or simultaneously. As the peak of the load on the 27th Street station occurred later in the day than that in the downtown district, the plan of building double-current generators was especially desirable, because by utilizing their capacity to carry at different times of day the peak load of both districts it obviated the necessity for separate machines for each peak, which would be required if two classes of generators were used. As a result, the first double-current direct coupled dynamos ever used for d. c. and a. c. lighting systems were manufactured and installed during the summer of 1898. A 600-h. p. engine already in use and direct connected to two 200-kw. direct-current dynamos was provided with an extended sub-base and outboard bearings, and a new armature and fields were put on, to provide the necessary frequency and collecting and commutating devices. During the present year an additional unit of the same size has been installed.

This in brief is a history of the installation, a description of which can be but general, as the details of the work are many.

In the plant at Harrison Street and the river there are two units, each consisting of a 600-h. p. Southwark vertical triple-

FIG 3.—ONE OF THE INDUCTION REGULATORS SHOWING THE HAND GEAR, THE SMALL CONTROLLING MOTOR WITH ITS REVERSING SWITCH, THE FLEXIBLE LEADS TO THE MOVABLE SECONDARY AND THE DAMPER FOR CONTROLLING THE AIR BLAST.

expansion condensing engine direct connected to 200-kw. dynamos built by the General Electric Company, one at each end of the shaft. Each dynamo consists of a special single-wound armature, the coils of which terminate in a large commutator, about five feet in diameter and of ample cross section to carry the entire output of the dynamo in direct current. The brushes are of carbon of the radial type and are shifted and adjusted by means of a hand wheel, as is customary on large machines. A view of one of these machines is shown in Fig. 6.

The direct-current sides of these generators are connected in series to form a three-wire unit, supplying current through a standard d.c. low-tension panel on the switchboard in the gallery to the three-wire bus bars which furnish the bulk of the current for the downtown network.

Connected also to the armature windings are leads terminating in three heavy collecting rings, of smaller diameter than the commutator, and located practically within it, the commutator spider being cup-shaped and overhanging the collector rings. Bearing on each ring are twelve tangential copper brushes which carry off three-phase currents at about 80 volts pressure. There are 20 poles to each dynamo and the speed being 150 r.p.m., they give a frequency of 25 cycles, which is considered the best for transmission and power work.

The complete circuits from the direct-current bus bars to the high-tension transmission lines are shown in Fig. 2. From the collector rings of each dynamo, as this figure shows, the three-phase currents are conducted through six 750,000-c.m. asbestos covered cables to an induction regulator in order to give a control of the alternating-current pressure without varying the field strength, which must necessarily be adjusted to give the proper direct-current voltages. By means of the regulators the voltage may be raised 7½ per cent. or lowered 7½ per cent., giving a total range of 15 per cent. of the initial voltage. Each regulator is of 15-kw. capacity and is air cooled by forced draft. As is well known, these regulators, which are of the General Electric Company's I. R. T. type, have no moving contacts but are adjusted by moving an iron core which varies the inductive effect of a shunt winding upon a series coil. This core may be moved by hand, but for convenience in operating from a distance, there is installed a small three-phase induction motor to drive the core by a worm gear and this is controlled from the switchboard as described below.

From the regulator the current passes to three single-pole switches by means of which the two machines on one engine may be thrown together on the a. c. end or disconnected from each other or from the line. From the switches the current passes to six fuse blocks, which form the terminals of the low-pressure windings of the three 150-kw. air-blast transformers. Each leg of the three-phase circuit forks to two fuse blocks, thus giving each of the three low-tension transformer windings, which are delta connected, a fuse of its own at each of its terminals, so that if one transformer goes out the other two will remain working, as they would not if there were only three fuses, one in each leg. Each transformer is provided with two independent low-pressure windings, which magnetize the core. By this method one set of transformers can be used for the two dynamos comprising one unit without making electrical connection between the windings of the two generators. As the two generators are electrically connected in series with each other on their direct-current sides, any electrical connection on their alternating-current sides would of course become a very complicated short circuit.

There are two high-pressure windings in each transformer which can be connected either in multiple or in series, giving a potential of 4500 or 9000 volts. At present 4500 volts pressure is used. The high pressure leads of these transformers terminate in six high-pressure fuse blocks of a special design, known as the expulsion-type fuse blocks. The leads are brought through the panel board encased in hard rubber bushings, the current being carried from them through flexible connections to two hinged terminals which are pulled apart by springs. The fuse of stamped metal passes through two lignum vitae blocks, provided with air chamber and vent hole on one side, and is fastened at each end to these hinged terminals. The fuse being in a state of tension is pulled apart before it quite reaches the melting point and is withdrawn from the air chamber, so that only a very small amount of the metal is volatilized and the violence of the dis-

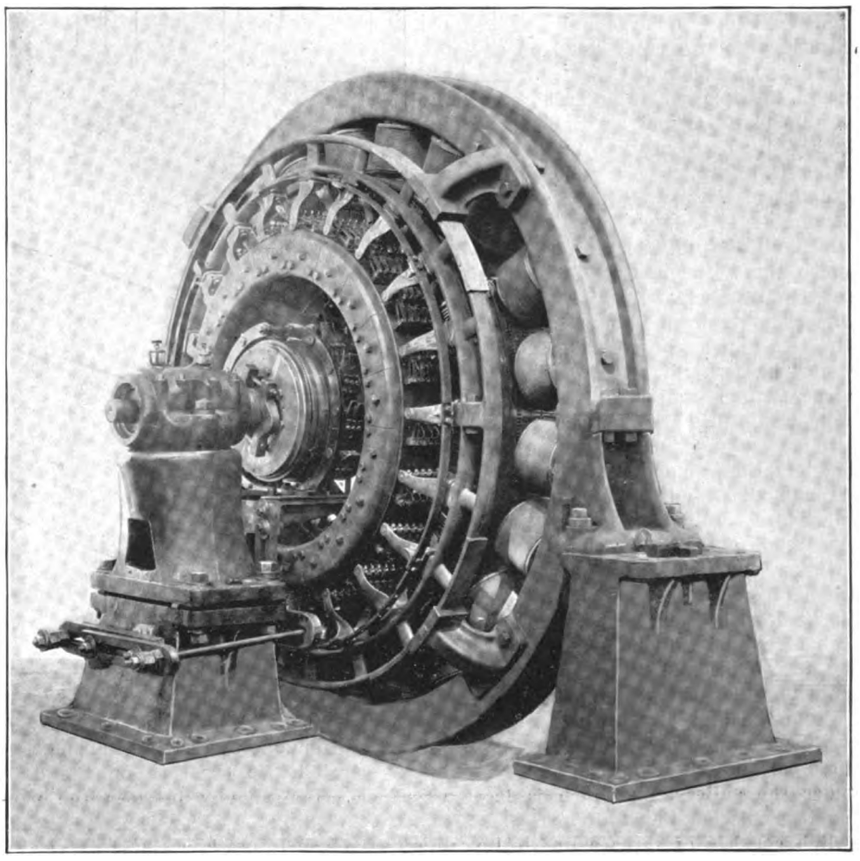

FIG. 4.—ONE OF THE DOUBLE CURRENT GENERATORS ERECTED IN THE SHOPS FOR TESTING, SHOWING THE COLLECTOR RINGS SUNK WITHIN THE COMMUTATOR SPIDER.

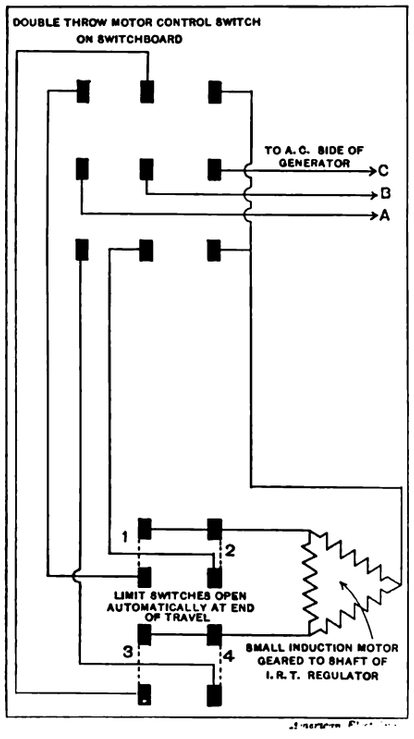

FIG. 5.—THE CIRCUITS OF THE CONTROLLING MOTOR OF AN INDUCTION REGULATOR, SHOWING THE METHOD OF REVERSAL AND THE ARRANGEMENT OF THE LIMIT SWITCHES.

ruption under high voltage and heavy load is therefore greatly reduced.

The six transformers and four induction regulators of the four dynamos constituting the two units stand on a platform in the middle of the floor space, between the two generator units. A view of this platform and apparatus is given in Fig. 1. There are two regulators and three transformers for each unit. Under the platform and enclosed by sides of marble is a large air chamber in which all the electrical connections between transformers, regulators and fuse panels are made. Air is forced into this chamber by a blower, driven by a direct-current motor, whose speed is controlled by a speed regulator, so that the proper volume and pressure of air may be maintained in the chamber. The transformers are provided with dampers which regulate the amount of air passing through them individually and may be adjusted according to the division of the load between them. On the sides of the chamber, mounted directly on the marble, are the high-pressure expulsion-type fuse blocks described above and the low-pressure fuses and switches, the former being away from and the latter facing the units to which they belong.

From the high-pressure fuses a three-conductor cable conveys the current to a three-pole switch of special type placed under the gallery, on which is located the transmission line switchboard. The switch consists of three cylindrical vessels filled with oil, in each of which one lead of the three-phase circuit is broken. The terminals and connections are arranged so that there are four breaks in series on each pole; each break being about four inches in length, which insures safe opening of circuit under any degree of load. The switch is operated pneumatically—the valves being controlled electrically from the operating panel—and can be locked open or closed by means of the special switch described below controlling them. Fig. 9 gives a view of the three switches of this type, one for each generating unit and one for the rotary converter.

The most interesting and important part of the entire installation is the regulating board, located in the switchboard gallery, a view of which is reproduced in Fig. 7. The direct-current panel for each unit is of the standard type used for three-wire direct-current central station work. The fields are bus-excited and the necessary regulation of the field strength is done by resistances controlled by parallel clip switches on the d. c. panels. Immediately between the panels controlling the d. c. side of the double-current generators is a single panel containing all the a. c. regulating and controlling devices for the two units or four three-phase generators. At the top of the panel are four indicating wattmeters, showing the output in watts of each generator. Below these are the phase lamps—two for each unit—which show when the units are in synchronism and ready to be thrown in multiple. Between the two sets of phase lamps is an a. c. voltmeter, and below it a double-pole multiple point switch, by means of which the voltmeter may be connected to any one of the generators. Below the voltmeter and switch are two three-pole double-throw knife switches—one for each generator—each of which controls the small three-phase motor mentioned above mounted on the induction regulator for raising or lowering the pressure. Below these are two multiple point switches—one for each unit—and connected to the phase lamps for that unit. There are also two special contact switches for operating the electro-pneumatic high-pressure oil switches. On the bottom of the panel are four single-pole knife switches, with high resistances connected across their terminals, for opening the field circuit of each generator.

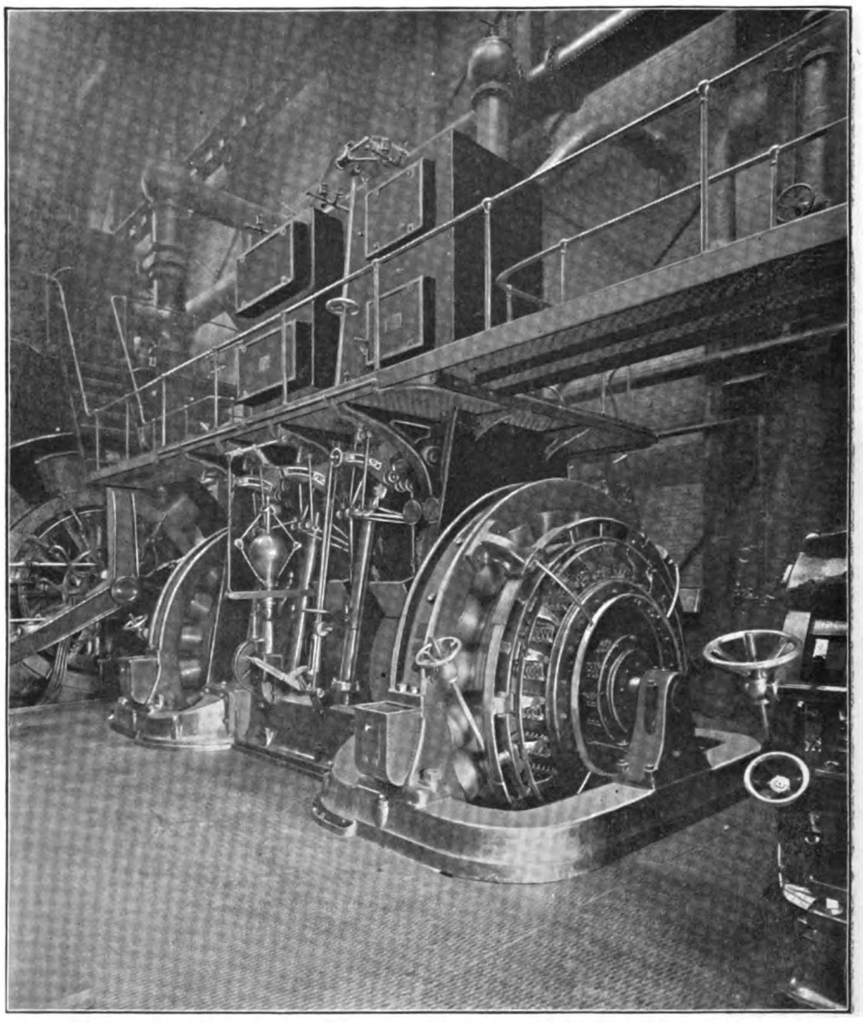

FIG. 6.—ONE OF THE DOUBLE-CURRENT GENERATING SETS COMPLETE IN THE STATION.

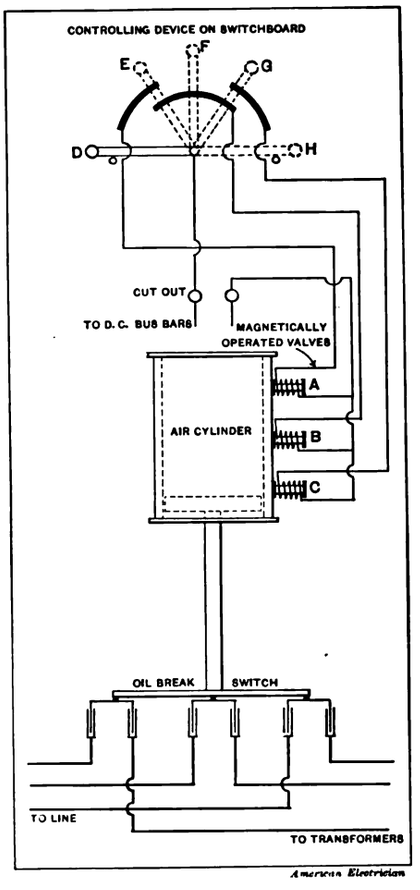
The controlling apparatus of the electro-pneumatic switches is shown diagrammatically in Fig. 8. The direct current

Digitized by Google

enters the apparatus from the d. c. bus bars and passes under control of the hand switch in the upper part of the figure to one or more of the magnets, A, B, C, on the air cylinder. In the position, D, in which the switch is shown open, there is no circuit through any of the magnets. When the switch is rotated to the right it strikes a segment carrying current to magnet, A, which works an auxiliary air valve which operates the main valve, admitting compressed air to the upper end of the cylinder and opening the lower end to the atmosphere. The piston is by this means forced down, closing the switches attached to its cross head. A further movement to the right brings the switch arm in contact with a segment closing the circuit through magnet, B, which is a mechanical latch holding either valve A or C open, except when B is energized. A further movement to the right operates magnet C, admitting air below the piston and forcing it up, thereby opening the main oil break switch.

All the various functions of operation and regulation of these generators can be accomplished by the regular switchboard attendant from this panel on the gallery, and the entire installation is thus under his control, enabling it to be handled quickly, conveniently and economically. There are no leads to the a. c. panel carrying heavy currents or high pressures. The heavy current leads run directly from the generators to the transformer stand and are very short. The indicating wattmeters are connected by means of small secondary wires to series transformers inserted in one leg of the leads from each generator. On another panel are four a. c. ammeters connected to these same wires, which show the number of amperes generated, whether energy or wattless current, and indicate any cross current or hunting between generators.



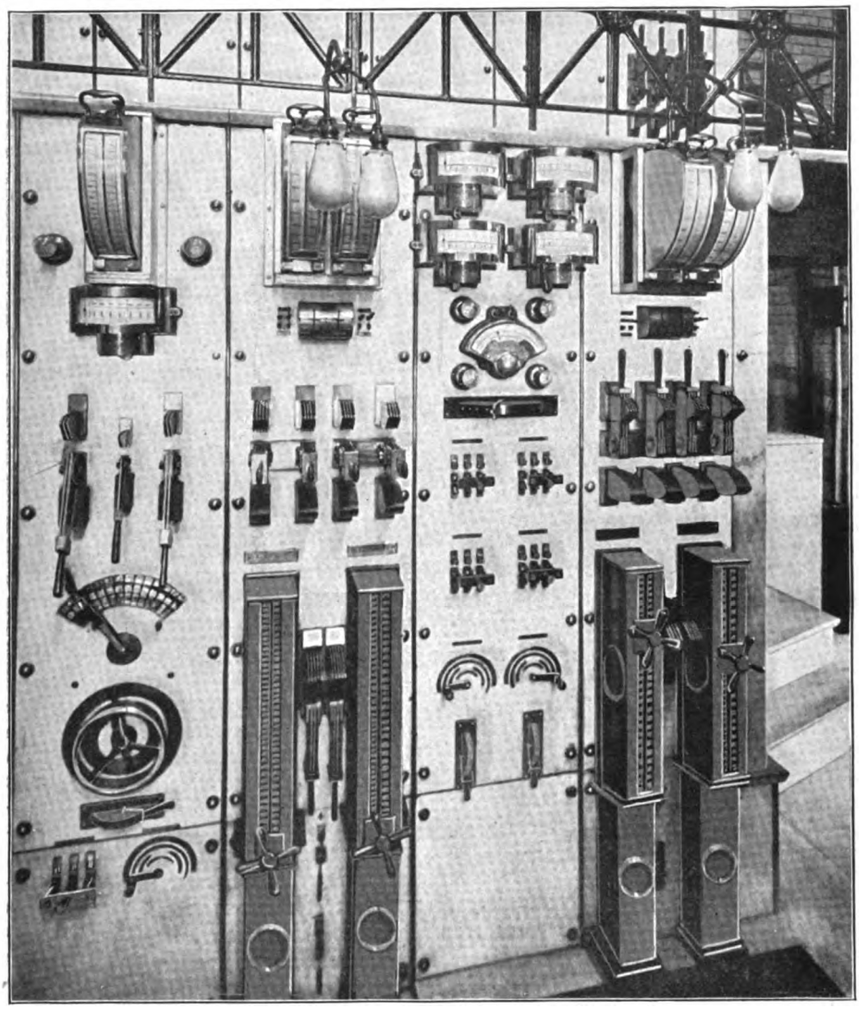


FIG. 8.—THE CIRCUITS OF THE CONTROLLING DEVICE OF AN ELECTRO-PNEUMATIC SWITCH, SHOWING THE METHOD OF OPERATING THE VALVE MAGNETS AND INTERLOCKING THEM.

FIG. 7.—THE SECTION OF THE MAIN SWITCHBOARD CONTROLLING BOTH THE DIRECT-CURRENT AND THE ALTERNATING-CURRENT SIDES OF THE ROTARY CONVERTER AND OF THE TWO DOUBLE-CURRENT THREE-WIRE GENERATING UNITS.

The phase lamps are connected through the double-pole multiple point switches above mentioned to one phase of the generator leads. Each unit has its own phase lamps and its own switch, by means of which it may be connected to the other unit or the converse rotary converter, without touching any other part of the panel than that containing the apparatus controlling that unit. By means of the multiple point switch below the voltmeter that instrument may also be connected in parallel with one of the phase lamps so that the needle will indicate simultaneously with the lamps when the generators are in step.

The three-pole double-throw knife switch for controlling the motor, which rotates by means of a worm gear the movable part in the induction regulator, is connected so that by throwing the switch up the motor will run in a certain direction and raise the pressure. By throwing the switch down the motor will be reversed and the pressure lowered. The circuits of this switch and the mo-

Digitized by Google

tor are shown in Fig. 5. The three-phase current enters through the wires, A, B, C, to the hinges of the throw-over switch. Leg C goes right through to the small induction motor whether the switch is up or down. Legs A and B go through other switches located on the machine and numbered respectively in the diagram, 1, 2, 3 and 4. These are limit switches, which prevent the small induction motor from turning the regulator too far in case the switchboard attendant tries to raise or lower the voltage beyond the capabilities of the regulator. In case he leaves his switch in the upper position, switches 1 and 3 are opened automatically when the regulator reaches its highest boosting position, thus stopping the small induction motor, but it is obvious that this does not cut it out of circuit when the switchboard attendant throws his switch over to the downward position when circuit of legs A and B is made through switches 2 and 4. These, however, open when the regulator is depressing the voltage by its maximum amount, to prevent the motor from running too far in that direction. The extent of the arc through which the movable part of the induction regulator may be turned is thus limited automatically.

The convenience of this method of regulation of pressure is most marked and can be best appreciated after an attempt at hand regulation with the aid of an assistant on the floor. The two double-current units and the 250-kw. converse rotary, which is controlled similarly by devices on the panel adjacent to that for the large units, may be operated in multiple and transmit a total of 1050 kw. for power purposes.

The principal purpose of this installation is to furnish current for the sub-station at 27th Street and Wabash Avenue, to be distributed from that point by means of rotary converters to the three-wire network of that district. The line for the transmission of the three-phase current from the Harrison Street station to the 27th Street station consists of two three-conductor cables, laid in ducts the entire distance of 3½ miles. These cables are each No. 2/0 B. & S. gage, with paper insulation, designed for 20,000 volts pressure, and are encased in lead sheathing covered with jute. At each end of the line each cable terminates in three single-pole quick-break knife switches of special design, by means of which either cable may be disconnected from the line at will. These are mounted on a marble board with barriers of slate placed between them and are opened by a pole hook in the hands of the operator. On the board at the transmitting end is a wattmeter which records the entire electrical energy transmitted; and a voltmeter which indicates directly in volts the pressure on the transmission line, as well as two ammeters, one on each transmission cable. A view of this board is shown in Fig. 10, and its circuits are shown in the lower right-hand corner of Fig. 2.

At the receiving end of the line are the necessary apparatus and appliances for reducing the pressure, changing the current to direct and distributing it over the feeders of the three-wire network.

This installation cannot be described in detail in the space of this article, but in general consists of the following:

A high-tension switchboard with switches and fuses for each set of transformers; three sets of three 150-kw. air-blast transformers; five induction regulators; two 100-kw. 125-volt rotary converters; two 200-kw. 125-volt rotary converters; one 250-kw. 250-volt rotary converters; with the necessary low-tension switchboard for regulating and controlling both a. c. and d. c. sides of the rotaries.

There has just been installed a 4000-ampere-hour storage battery at an eight-hour rate in this station to carry part of the peak load and to furnish higher voltage current for some of the long feeders in remote sections of the districts.

Another important function of the double-current generators is the furnishing of three-phase current for power purposes in large factories. A line has been installed to the factory of the Crane Company, the well known makers of valves, in which are operated three-phase induction motors aggregating 200 h. p. The current is brought into the building at a pressure of 220 volts from a set of three 75-kw. transformers, which are mounted in a special transformer house built between two poles just outside the building, the line carrying 4500 volts being brought on poles from the station. Lightning arresters are placed on each end of the circuit. The special switchboard in the station from which the line receives the high-pressure current is shown in Fig. 11, and the arrangement of its details in the circuit is represented in Fig. 2. As will be seen from the latter figure, a tap is made on the transformer side of the oil switch of each of the double-current units, and three lead covered cables are carried to the Crane Company's board. One set of leads thus brought in is connected to the top and the other to the bottom terminals of three single-pole, double-throw, quick-break knife switches; the line being connected to the middle points, so that by throwing the switches

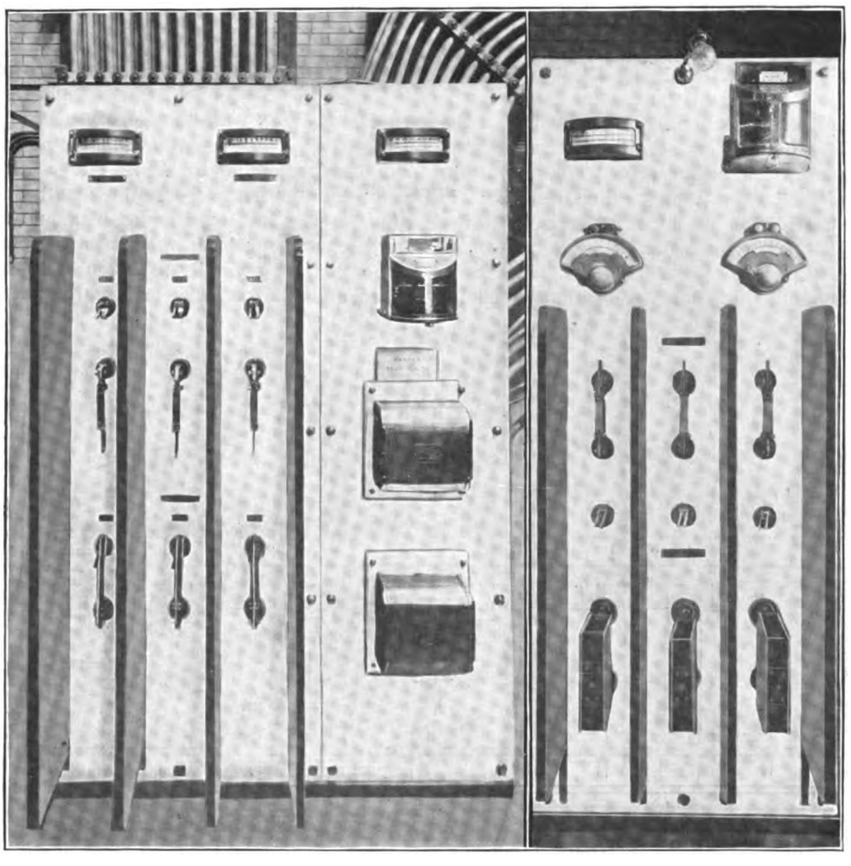

FIG. 10.—THE SWITCHBOARD OF THE TRANSMISSION LINES.

FIG. 11.—THE SWITCHBOARD OF THE POWER LINE.

up or down, the line may be thrown on either generator unit independently of whether either or both units are working singly or in parallel on the bus bars and transmission line.

The double-current machines in this station give an excellent opportunity for comparison with direct-current machines, since they stand immediately adjacent to three-wire sets of exactly the same output and exactly the same speed in revolutions per minute. In fact the first double-current unit is driven by an engine which originally drove direct-current machines and is a duplicate of other engines standing next to it and still driving such generators. The differences in appearance are as follows: A double-current machine necessarily has 20 poles to obtain the proper frequency, instead of the 6 poles on the direct-current machine, and in order to avoid crowding these poles the diameters of the yoke ring, the armature and the commutator have been increased and the machine has been shortened axially somewhat to compensate for this increased diameter. The narrower pole face necessarily reduces the number of slots and commutator segments per pole which can be used, which number in the double-current machines is 21, about ¼ of that in the older dynamos. This increases considerably the voltage generated per commutator segment, but proper commutation has been attained by using carbon brushes.

It will be seen that a great flexibility of operation is obtained by means of the apparatus above described. Each double-current generating unit can be used simultaneously to furnish current for the direct-current system, three-phase current for the transmission line and for the power line—either alone or in multiple with the other machines—and to the extent of its capacity on either the d. c. or a. c. side. The converse rotary may furnish current for the transmission line and one generator unit furnish current for the power line, independently of each other, or they may be run in multiple, or one generator unit may furnish current for both transmission and power line, or the second generator unit may be run in multiple with the converse rotary on the transmission line, independently of the generator unit on the power line, or all three may be run in multiple on the transmission and power lines—each generator furnishing direct current at the same time to the three-wire bus bars.

Thus the company is able to run its dynamos and engines at the point of greatest efficiency all the time and secure the best economy in operation with a smaller number of units, a more uniform system of apparatus and less investment in machinery.

The field thus opened up is capable of vast extensions and the realm of double-current generators for light and power business is almost limitless.

## THE ISOLATED PLANT OF A WHOLESALE GROCER'S ESTABLISHMENT.

Chicago is pre-eminently the city of large jobbing houses, among the most important of which are naturally those devoted to the collection, sale and distribution of the various food products raised largely in the adjoining States, shipped into Chicago, and there treated, prepared and sold for consumption to a large extent in the same districts. The running of a wholesale grocery involves more than the mere purchase and sale of food commodities, the raw material being to quite a large extent converted into more finished products. The processes require a large amount of labor which can be greatly economized by the use of many unusual types of machines, requiring the distribution of a considerable amount of power in small units. The peculiarity of this power distribution is the fact that the demand in any one department is quite intermittent. The baking-powder machines may be running one day and idle the balance of the week. The mince meat cutters have heavy duty in the fall of the year, and catsup kettle stirrers have their season of activity when tomatoes are ripe, etc. The result is a large amount of idle power-transmitting apparatus, which, if the transmission is mechanical, consumes a larger portion of the power generated than does transmitting apparatus with such a low load factor as that even of a machine shop.

A test of the equipment of the old house which the building described below supersedes, showed that some 65 per cent. of the power generated by the engine was wasted in the shafting and belting. This waste led to the equipment throughout of the building recently completed with electric power transmission. The structure is known as the Garrett Building and is a plain, but substantial, steel edifice built by the Northwestern University under special designs for the lessees, Messrs. Reid, Murdock & Company. The building is about 130x180 feet in size, ten stories high, with a basement, and is completely occupied by the wholesale grocery business of the above named firm. The first two floors are filled by the offices and shipping rooms, the upper three by the treating and manufacturing departments, and the others by warerooms of the materials kept in stock.

The isolated plant is an unusually complete one, and interesting, owing to the peculiar nature of the problems involved. The engine room contains three 75-kw. generators of a new type built by the Western Electric Company and containing some novel features, notably the protecting plates of the barrel wound end connections which are shown in Fig. 1. They are driven by two Erie Ball engines, and all engines and dynamos are in line and coupled together on the Arnold system. The general arrangement of the engines, generators and couplings on the shaft is shown by the plan, Fig. 2.

Digitized by Google

and in greater detail by the sectional elevation, Fig. 1. Both the engines are horizontal tandem compounds with single valves, and designed for the same speed, 275 r.p.m. The one to the extreme left of the line is rated at 125 h. p., while the other has a capacity of 250 h. p.

As will be seen, the larger engine has a dynamo either side of the crank, there being two dynamos between the two engines, the smaller engine being at one end of the line. Normally the larger engine is coupled to the two dynamos adjacent to it, while the smaller engine is coupled only to the third dynamo next to it. Running through the hollow shafts of the two dynamos between the engines is a smaller solid shaft with flanges by means of which it can be coupled to either or both of the crank shafts of the two engines or to either or both of the flanges fixed to the hollow dynamo shafts surrounding it.

The arrangement of these parts is best shown in Fig. 1, in which the solid central shaft is shown in two sections, B and B', coupled together at the center by the ordinary flange coupling, N. In spite of the fact that this shaft is in two pieces it is supported only by the bearings, M and M', close to the central flange coupling, the greater part of the shaft and the discs on the end of it overhanging the bearings at either side. This condition exists, however, only when the shaft is lying idle in its bearings, for when the shaft is in operation it is supported at both ends as described hereafter. Surrounding this shaft are the hollow shafts or quills carrying the dynamo armatures. Each of these quills is supported in independent bearings, such as K and L, the latter of which is on the same pedestal with bearing M. The shaft, B, carries at its left hand end a disc, C, which runs between the flange, E, keyed to the crank shaft of the small engine and the flange, D, fastened to the generator quill. The flange, C, of the inside shaft can be bolted either to the engine flange, E, by means of taper bolts such as that shown at I, or to the generator flange, D, or the engine and generator flanges can be bolted together by means of bolts such as that shown at G, or all three flanges can be rigidly fastened together if both sets of bolts are in place as the drawing indicates them. Normally the inside solid shaft is loose at both ends and stationary, but it can be coupled up to throw either the right-hand dynamo upon the small engine, or the left-hand dynamo upon the large engine, or both generators upon either engine, or finally to fasten both engines and all dynamos rigidly together.

By this means the failure of any one dynamo does not incapacitate either engine, or does trouble with the smaller engine throw out of service any dynamo, while failure of the larger engine only shuts down the right-hand dynamo. The larger engine is made with cylinder dimensions sufficient to carry with two dynamos the whole load, and a reserve source of power is ingeniously provided without using any other engine of the same size, by fitting the smaller engine with a by-pass in such a way that both its cylinders can be used

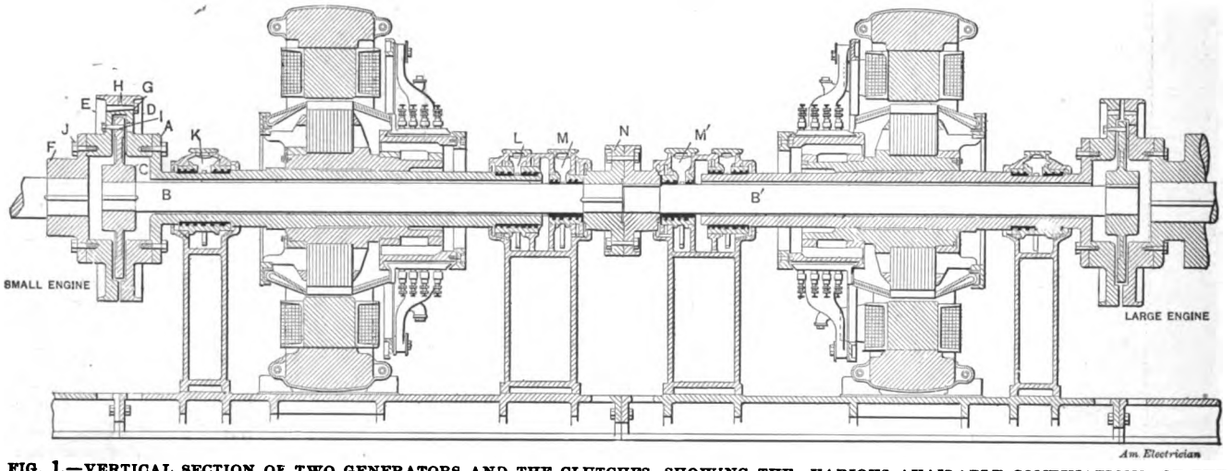

FIG. 1.—VERTICAL SECTION OF TWO GENERATORS AND THE CLUTCHES, SHOWING THE VARIOUS AVAILABLE COMBINATIONS OF THE ARNOLD SYSTEM.

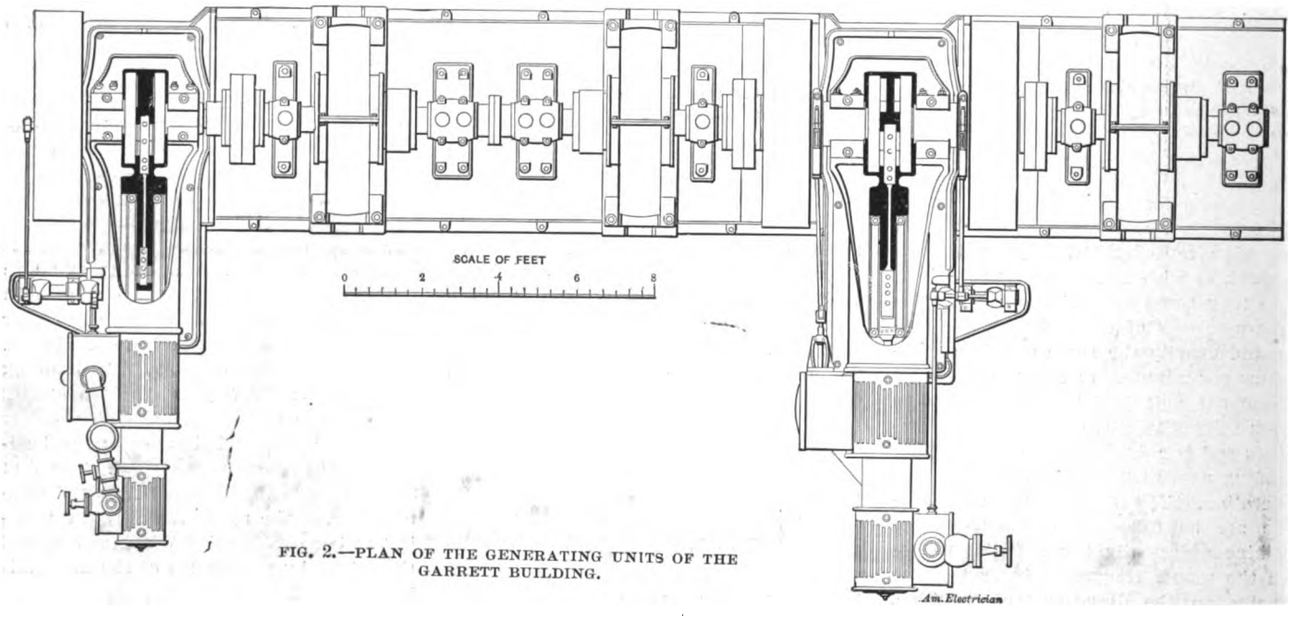

FIG. 2.—PLAN OF THE GENERATING UNITS OF THE GARRETT BUILDING.

Digitized by Google

high pressure, under which condition it will deliver double its rated load, or fully that of the larger engine working compound.

Thus the central solid shaft is only used in case of emergency. This emergency might be the disabling of one of the generators or one of the engines. In case the large engine should break down it would be possible, by means of this interior shaft and the three-way couplings at its ends, to operate two of the generators from the small engine. This would be accomplished by bolting the disc, C, keyed on the end of shaft B, to the small engine flange, E. This connection would insure the revolving of the interior shaft, and by bolting the disc on the other end of the shaft to the generator flange, the small engine could be made to operate the generator which is not immediately adjacent to it. At the same time the flange, E, of the small engine could be bolted to flange, D, of the generator contiguous to it, and in this manner both generators would be operated by the small engine. By reversing the connection the large engine could be made to operate two generators upon one side and one generator upon the other; that is, by working under an overload of 50 per cent., the large engine can operate the entire plant, while the small engine is capable of handling two-thirds of the total generator capacity. As the total load of the plant never exceeds the output of two generators, it will be seen that the small engine is capable of handling the entire load in case of a break-down of the large engine, while, if any one of the generators or the small engine should be crippled, the large engine is in a position to supply the demand. Even the simultaneous break-down of the large engine and the right-hand generator, or

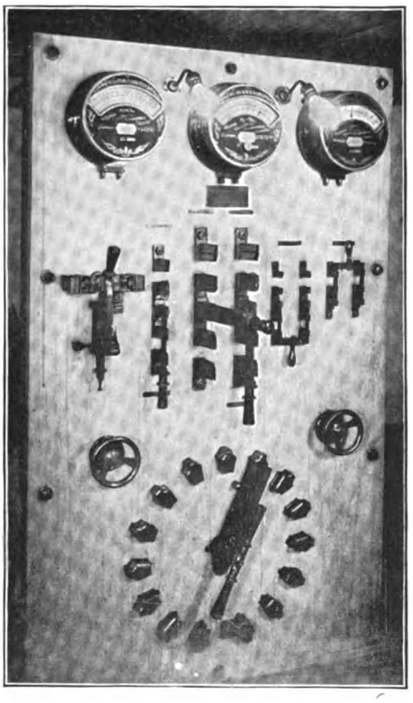

FIG. 3.—THE SWITCHBOARD CONTROLLING THE STORAGE BATTERY.

the small engine and any one generator would not reduce the capacity of the plant below the maximum demand.

To insure the same reliability with regular direct-connected units it would be necessary to install three engines and three generators. Thus one large engine is used in place of two smaller ones, giving better steam economy on large loads and yet a small engine is available for light loads. This arrangement, therefore, not only costs less for machinery, but gives a more compact plant, requires less steam piping and is more convenient to operate.

The bolted couplings are designed so that they may eventually be replaced by magnetic clutches, the latter not being installed, as the load is a reasonably steady one and capable of being carried temporarily by the storage battery while the generating plant is shut down for changing couplings.

The bearings, slides, etc., of the small engine have been prepared for this extra duty, the frame being that standard for 150 h. p., and its ability to perform this service has been proven by continuous operation under this load. Steam at full boiler pressure of 150 pounds is not admitted to the low pressure cylinder of the smaller engine, a reducing valve being inserted to hold the admission pressure of the low pressure cylinder down to about 60 pounds. The generators are supported on an iron sub-base extending between and bolted to the engine frames. The pedestals are supported on liners, and dowel pins, in addition to the ordinary bolts, have been inserted in order to maintain the accurate alignment necessary with such a large number of journals in line with each other. The generator frames are split vertically in order that they may be pulled apart and removed if necessary, without disturbing the double line of shafting running through them, thus allowing convenient access to the field and armature coils.

The plant is non-condensing, exhaust steam being used for heating purposes in the winter season.

The introduction of the storage battery and its use without a booster directly in parallel with the generators has involved some peculiarities in the switchboard arrangement. The main switchboard, which

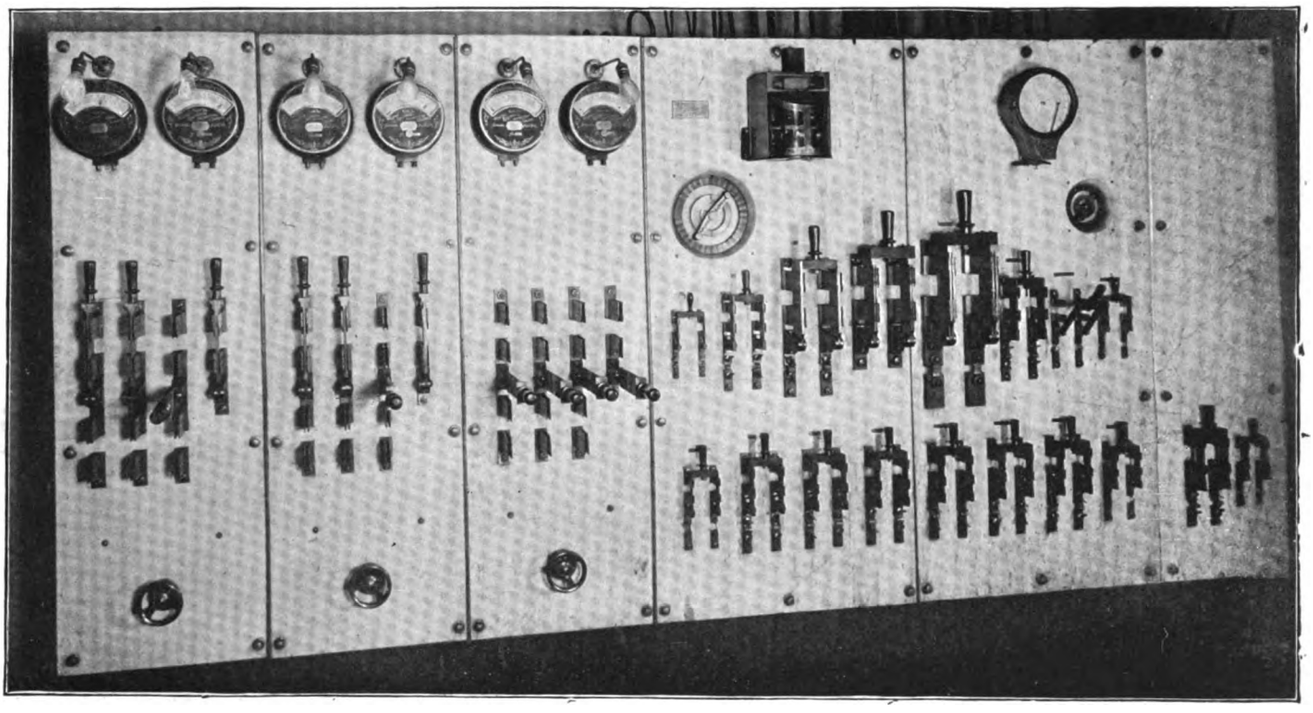

FIG. 4.—THE MAIN SWITCHBOARD, SHOWING UNIQUE ARRANGEMENT OF MAIN SWITCHES ON GENERATOR PANELS TO THE LEFT.

Digitized by Google

does not contain the battery equipment, is shown in Fig. 4. The three panels to the left are devoted respectively to the three generators, and each contains, as may be seen, three single-pole, double-throw switches and one single-pole, single-throw switch. The purpose of these switches is to run the machines either shunt or compound on either the lighting or the power bus bars. The arrangement of these connections is shown in the left-hand side of the diagram, Fig. 5. Here it will be seen that the left-hand switch, A, when thrown up, connects the negative brush of the dynamo to the negative lighting bus, and when thrown down, to the negative power bus. The next switch to the right, B, performs the same function for the positive terminal of the machine. The switch, C, next to the right, is connected to the equalizer lead, that is, to the positive brush of the machine. In case this switch, C, is thrown in, the machine works as a plain shunt dynamo, whether the switch, B, to the left of it is closed or not. If the latter is also closed, the series field is short circuited, and if open, all current must pass direct via switch, C, from the brush to the bus bar without going through the series field. The single-throw switch, D, to the extreme right of the group, is an equalizer switch, used when running the machines compound. This is used when working upon either the lighting or the power bus, a separate equalizer for the two services being unnecessary, as there are only three dynamos, a number insufficient to give a pair for lighting and a pair for power. Thus with switch A and switch C up, the machine is operating as a straight shunt dynamo upon the lighting bus bars, and with switch A and switch B down, the machine would operate as a compound dynamo upon the power bus bars and could be thrown in parallel with another machine by closing the equalizer switch, D. This unusual equipment of switches is desirable in order to group the dynamos at times in parallel with the storage battery on the varying load due to the current taken by the elevators and stationary motors of the plant, when compound winding without a battery booster would make the distribution of the load unstable. At times when the battery is not in parallel with the machines they can be over-compounded as is usual in such plants.

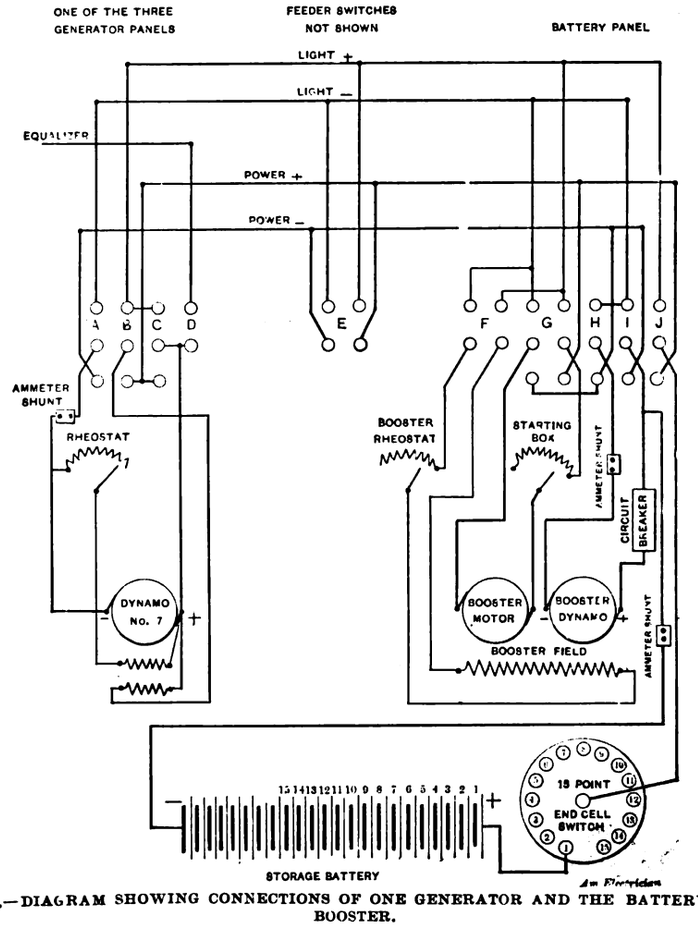
Another novelty on the switchboard is the use of one integrating wattmeter with flexible cords and plugs by which it can be connected into any feeder. For this purpose there is cut into each feeder behind the board a removable copper strap with plug sockets above and below it, in which the wattmeter plugs can be inserted, the strap being then pulled out to throw the current through the meter.

The voltmeter is fitted with a Mabbs voltmeter switch by which it can be thrown to any machine, to the bus bars or to ground from either bus bar. One of the machine ammeters is also fitted with a Mabbs ammeter switch by which it can be thrown on to ammeter shunts respectively connected one in its own machine circuit and one in each feeder circuit. Thus this ammeter can be used whenever it is desirable to do so and at an instant's notice to measure the current on any feeder.

The battery consists of 115 cells of 15 F. chloride accumulators (the plant being throughout a two-wire 220-volt system). This size of battery was chosen on the principle that a storage battery for this service should have at an eight-hour discharge rate about one-third the ampere capacity of the generators. The cells are mounted in glass cases in sand trays on oil insulators, on racks two tiers high, in a special battery room.

The battery switchboard is a separate affair, shown in Fig. 3. Its circuits are indicated at the right hand side of Fig. 5. It is fitted with a 15-point end-cell switch operated by hand, in addition to which there is also installed a motor-driven booster. This booster is solely used for charging and is not differentially wound in order to render the battery capable of discharging in parallel with compound wound generators. The booster motor is supplied through a double-pole, double-throw switch, G, from either the lighting or power bus bars. Switch H throws the booster in series with the battery from either the light or the power bus bars, and switch, I, connects the negative end of the battery to either the power or the light bus when the booster is not used, while switch, J, is used when the battery is in operation either with or without the booster.

The generators normally run plain shunt in parallel with the load and the storage battery, the voltage of the latter being regulated by means of the end-cell switch. Occasionally they are run compound on the load, the battery being disconnected. Provisions are such, however, that the load can also be run on the machines either shunt or compound, the battery being at the same time charged through the booster, or the load can be put on the battery while the latter is connected with the machines through the booster.



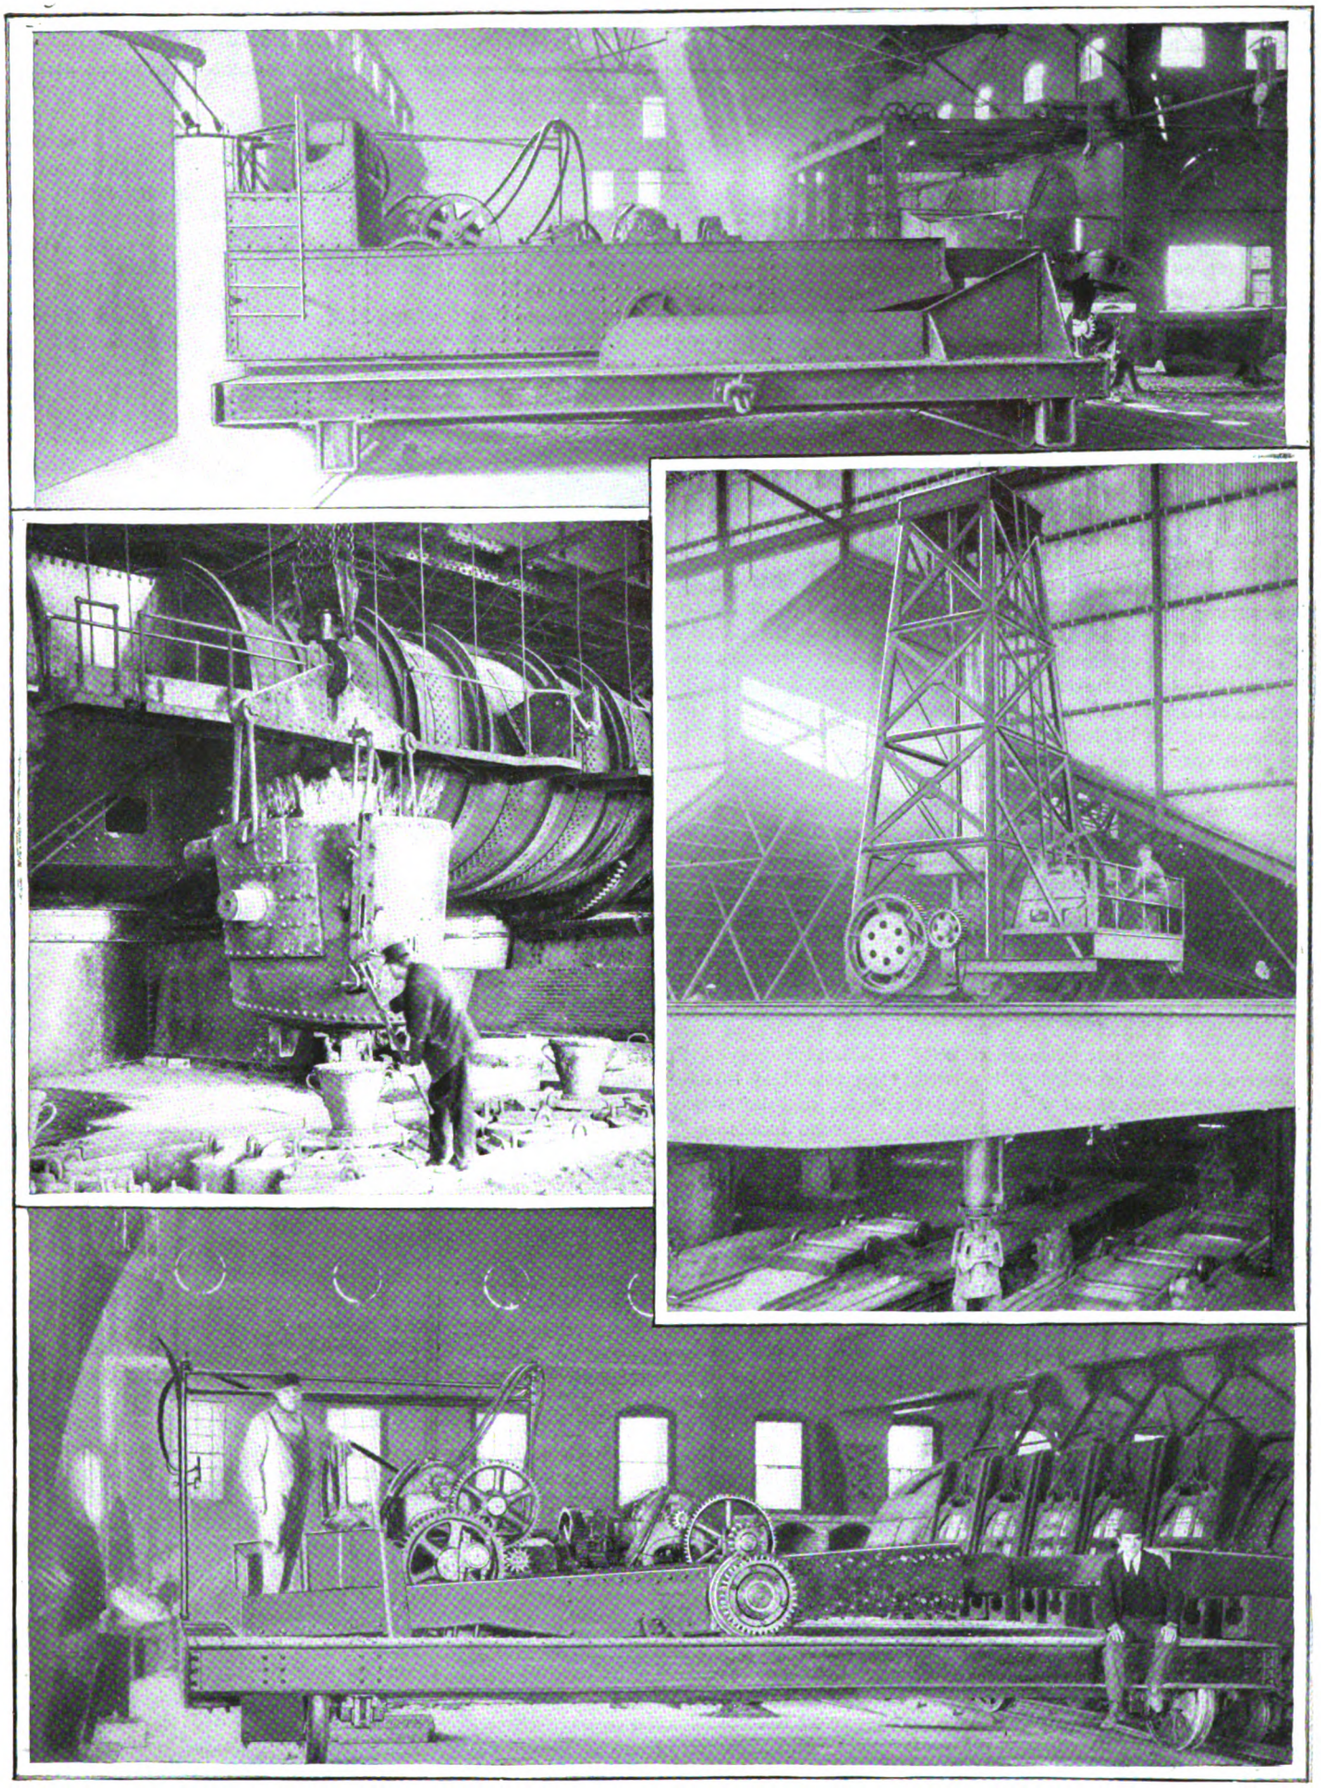


FIG. 5.—DIAGRAM SHOWING CONNECTIONS OF ONE GENERATOR AND THE BATTERY AND BOOSTER.

Throughout the building there are some 45 motors with an aggregate capacity of 350 h. p. all told, exclusive of the elevator motors. Of the latter there are 6, all Otis machines, 5 being rated at 25 h. p. each and one at 50 h. p., besides one dumb waiter. The large motor drives one 6000-pound freight machine at 250 feet per minute. The motors have all sorts of peculiar loads. In addition to those mentioned above there are carbonizers, bottling machines, raisin seeders, olive stoners, salad mixing machines, onion cutters, cucumber cutters, mustard pumps, centrifugal wringers, coffee conveyors, elevators

and roasters, in addition to such ordinary loads as printing presses, etc. Of these motors about 40 were made by the Northern Electrical Manufacturing Company, and all of these are low speed, shunt wound and fitted with 15 per cent. speed regulation by means of field strength variation. All motors are controlled by Cutler-Hammer motor starters.

Down in the engine room are various motor-driven auxiliaries having an aggregate capacity of some 90 h. p. These motors drive the ice machinery, the air compressor for the pneumatic message system, the air fans for the indirect heating system and one air compressor for a pneumatic sewage ejector. The latter is entirely automatic in operation, the ejection of the sewage matter from the sump being automatically controlled by a float valve, and the compressor motor being in turn automatically controlled to maintain the air at 10 pounds per square inch by a Whittingham switch.

The wiring through the building presents several points of interest. The main feeders are carried up on porcelain knobs in a special feeder shaft, outside of which all wiring of current, telephone and signal service is carried in iron-armored conduit. This conduit differs from previous practice in being plain galvanized iron pipe of standard weight and unlined. The light and power wiring carried through it is double braided and covered with 1/32 inch more insulation than that customary in lined pipes.

The lighting throughout the building is entirely by means of 220-volt incandescent lamps, no arc lights whatever being used. The number of ceiling outlets throughout the warerooms is much greater than the number of necessary lamps, and each outlet, instead of being provided with a cord and socket, is simply fitted with a special receptacle. The men are given a number of cords and lamps fitted with attachment plugs which they can insert in these receptacles, thus keeping down the number of lamps connected but allowing the use of lamps in all desirable locations. The question of outlets on the office floors was a peculiarly difficult one in this building, as cords from overhead fixtures down to the desks were not wanted and the offices are in large rooms without provisions for getting at the desks from adjacent walls. No cords come down from the ceiling or electroliers in the two great office rooms which fill the first and second stories of the building, all lamps, telephones, annunciators, buzzers, bells, etc., being wired up through the floor. Under such desks as are fastened to the floor the conduit piping is brought up flush with the surface of the desk, a fixture bracket being screwed on above it, but with movable roll top desks this construction was not available. Pringle marine outlet boxes were used in this case for the telephone and signal wires, and Chapman receptacles in boxes with rubber gaskets for the lighting wires, these fixtures serving satisfactorily where they are located so as not to be trampled upon.

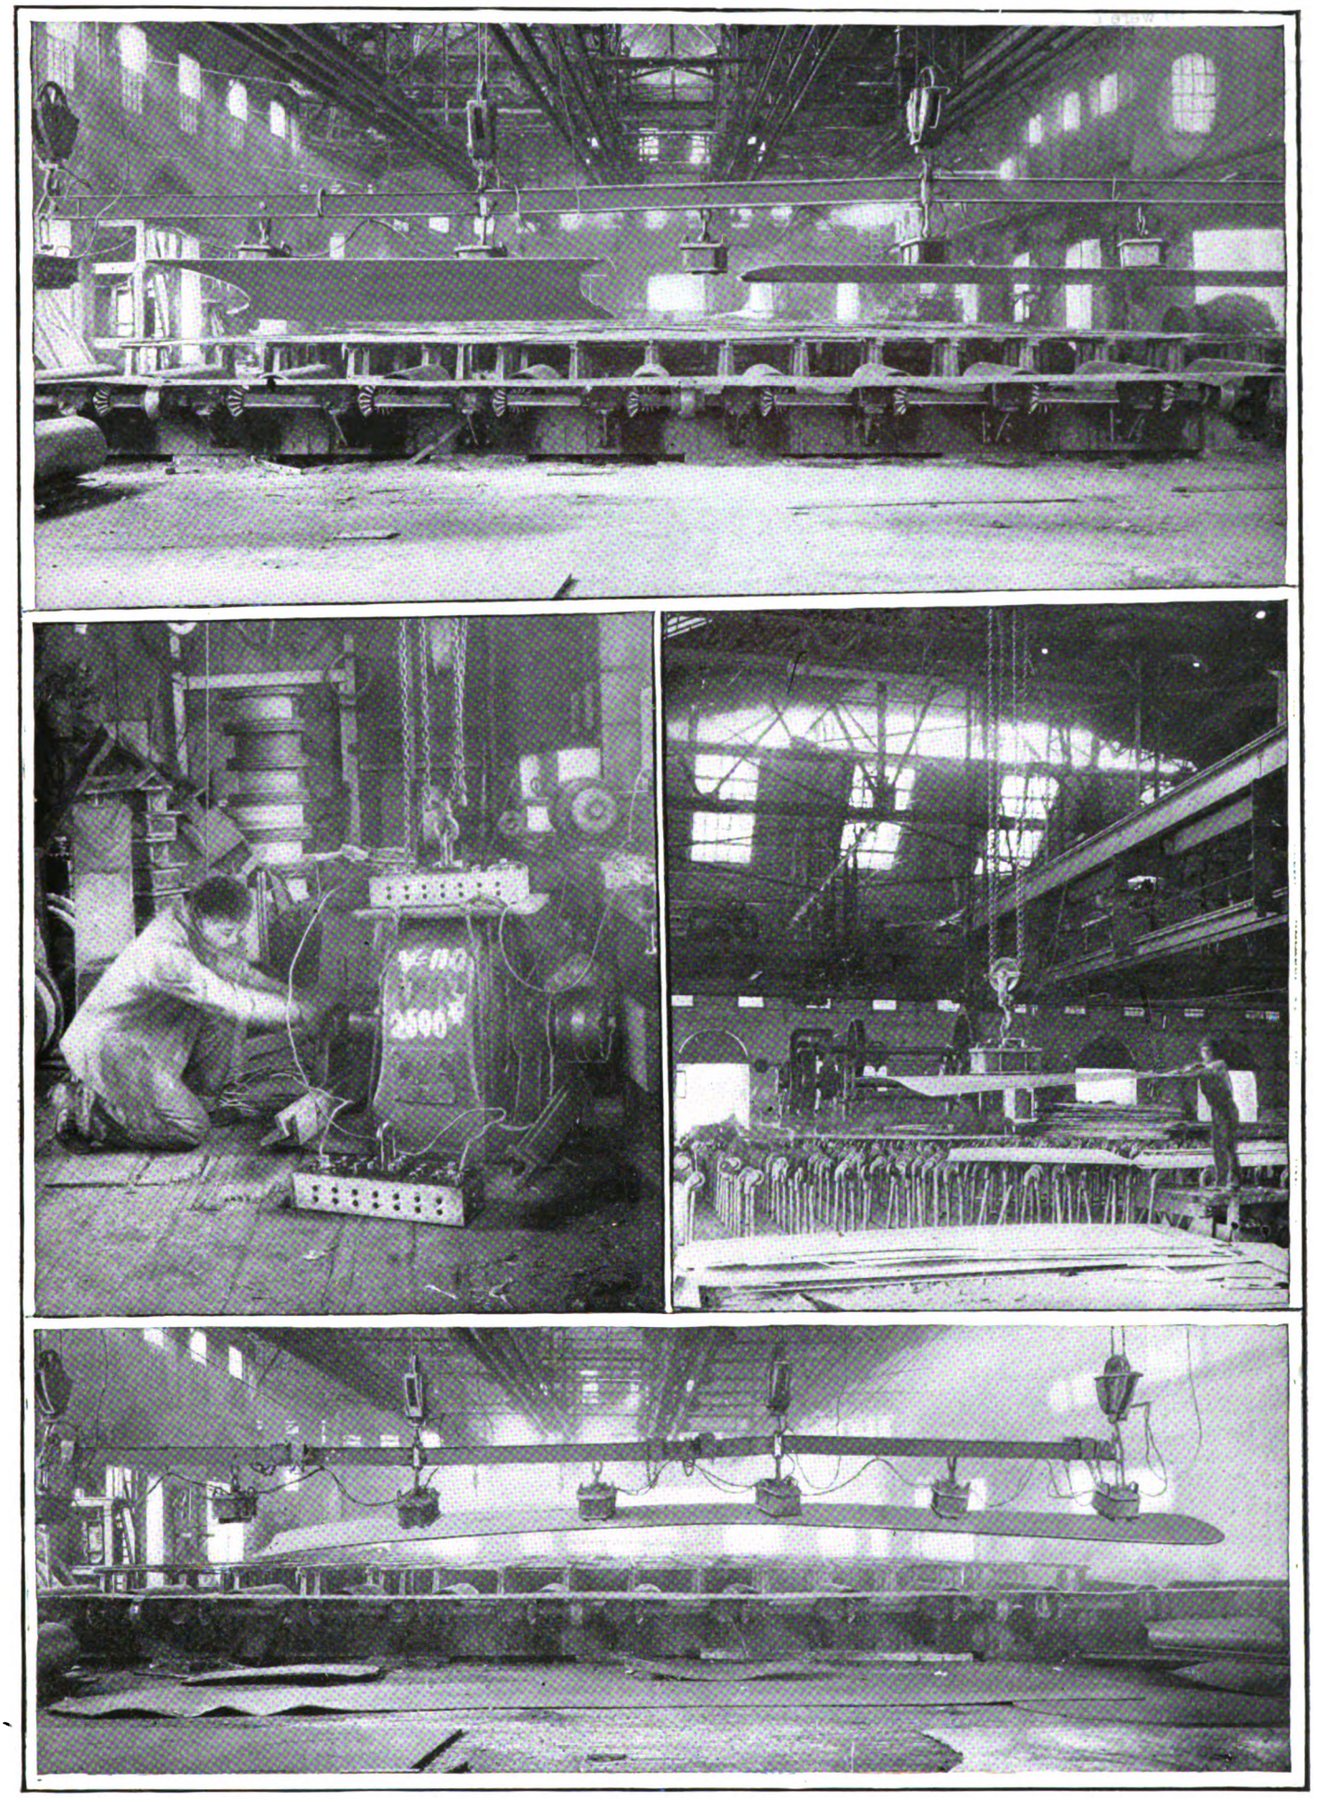
The telephone and signal service in these offices is worked out with unusual care. As is customary, a Bell private branch exchange is installed, but all of the 'phones wired to this exchange are not fitted for connection through over the trunk lines to the city system since a higher rate is charged for instruments so used than for those used only on private branch work. The private branch operators are therefore supplied with a call service with buzzers on the desks by which they can call any one wanted to the nearest long distance 'phone. The wires to these buzzers run in the same piping with the annunciator wires. The large number of lighting, telephone and signal conduits, annunciator and buzzer and special wires, with the compressed air message tubes and other pipes, gives under the second floor of the building an almost solid grillwork of iron piping.

The architects of the building were D. H. Burnham & Company, the work above described being under the supervision of the electrical and mechanical engineer of this company, Mr. Chas. M. Wilkes. The contract for the engines, generators, Arnold system, storage battery, booster, wiring and switchboard was given to the Arnold Electric Power Station Company, who sub-let the wiring and switchboard work to the Mutual Electric Company of Chicago.

# Electric Power as a Factor in Steel Mills.

It is gratifying to note the rapid development of electrical appliances for handling the metal in its various stages as it progresses through the different departments in some of the large steel mills of this country. Although electricity has been slow in entering this field, because of the very difficult problems to be solved, it is now getting a permanent hold and has given an opportunity for the display of engineering skill and inventive genius of the highest order to adapt it to the work in hand. Among the mills in which electricity has superseded direct steam power in a variety of distinct operations none are more interesting than the mills comprising the plant of the Illinois Steel Company at South Chicago, Illinois. This plant is located near the mouth of the Calumet River on the lake, and including the blast furnaces, covers about 450 acres, and in it are employed over six thousand hands.

The electrical devices are found mostly in the mills, as this power is not employed to any great extent about the blast furnaces except for lighting. In the open-hearth department motors aggregating 1200 horse power are employed, while about 600 motor horse power is found in the plate mill and the same amount in the slab mill. The application of motors in mills of this character is not, as many suppose, confined to travelling cranes merely, for while these are used both for handling the ladles and shifting materials, numerous other electrical machines are employed. Some are known as charging cars, others as ingot lifts, while in the slab mill the tables are shifted by motors, and there are motor-driven transfer tables for giving direction to the billets. Last, and most interesting of all, magnetic lifts and trolleys are employed in and about the plate mills.



The largest of the travelling cranes are found in the open-hearth furnace department, and here are four of 75-ton capacity each, which are employed for handling the ladles. Four of the furnaces are of the revolving type, and when a charge is ready for pouring, the ladle is brought into position by the crane. The furnace is revolved or tilted by means of a pair of hydraulic cylinders. The ladles are supported from the crane by stirrups and are filled to overflowing with the molten metal in order to remove the slag, which floats on the steel while both are molten. When ready, the crane swings the ladle into position over the ingot moulds, when the metal is allowed to flow into a funnel-shaped receptacle known as the fountain, which connects with the base of the four moulds so that the four are filled from the bottom simultaneously. Great accuracy is required in handling and adjusting the ladles, but electric power is found to meet the most exacting requirement. One of these ladles is shown in service on page 455.

The large cranes have each two traveling hoists, the small one being of 20-ton capacity, which is employed for turning the ladles when it becomes necessary to empty them of the surplus metal or slag. These lighter hoists are also employed for lifting light weights. The large cranes are each equipped with seven motors; two of these are connected in parallel for operating the main hoist, two similarly for the auxiliary hoists, and the others operate the two trolley travels and the bridge travel. In the same department are two other electric traveling cranes of thirty tons capacity each, which are operated for the lighter work, and there is also a 40-ton crane with which an auxiliary lift is also provided for handling the smaller ladles. A third 75-ton crane is about to be installed in which the engineer proposes to use wire ropes in place of the chains for the hoists, and for this purpose large sheaves will be employed. This change is made for the reason that it is difficult to forge large chains so that the links shall all have a proper factor of safety.

Passing to an elevated platform in the rear of the revolving and open furnaces, we find two charging cars which are employed for introducing the metal into the furnaces.

These charging cars, which are illustra-

ted on page 455, resemble the battering rams employed by the ancients. They are longest across the track on which they run, and the arm or ram has several movements; one tilts it up and down, another revolves it half way over on its axis, and tne third gives it an advance and retreat motion. All these movements are under the control of the operator, who stands on the off side of the car from the furnace and manipulates the levers that start the motors. The metal for the charge is cut by shears into suitable lengths and is packed in cast-iron pans or boxes of oval shape and about four feet in length and twenty inches wide and deep. These are brought in and placed on suitable racks along the face of the furnaces. Each charging box has a dovetailed shaped chamber at one end into which the end of the ram drops and it is locked in position. The box is then lifted and the car moves with it to the mouth of the furnace when the ram is extended, and as soon as the charge is well within the fire chamber the box is inverted and its contents dumped into the molten mass. The box is then righted, withdrawn and placed back upon its rack, when another is picked up and the operation repeated. The work of charging is done without exposing the operators to the excessive heat. Machines of the same type are also employed in the rail mill and one of the other mills for charging and drawing the blooms from the re-heating furnaces preparatory to rolling.

Above a platform, adjoining that on which the charging cars operate, is an ordinary electric traveling train for loading and handling the dolomite, which is crushed and employed for the floor and lining of the open-hearth furnaces.

In the plate mill electro-magnets, illustrated on page 457, are employed for lifting the plates. These are cheaper, safer, quicker to operate and are more efficient than chains and hooks. The largest lift is composed of seven magnets, which are attached by chains to a long beam, which, in turn, is suspended by wire ropes from overhead traveling trolleys, and these are propelled along the run by a motor-driven drum. This set of magnets is capable of picking up plates weighing ten thousand pounds and transporting them to any desired distance and dropping them in convenient proximity to the plate shears. Plates measuring eight feet wide and forty long, and from 5/16 to 1½ inches thick, are readily handled. Hot plates, however, are not transported by the magnet lifts, as the heat injures the winding of the nagnets. Some of the magnets are smaller than others. The small ones are of later construction and are made after designs furnished by E. B. Clark, Electrical Engineer of the company, and although less than one-fifth the size of the larger ones, are more powerful.

After the plates are cut to suitable sizes they are removed from the shears and deposited in the shipping yard by overhead traveling cranes having only a single magnet. Similar cranes are employed in the yard for loading plates upon cars for shipment.

For handling the heavy ingots in the rail mill, and for introducing them into and removing them from the soaking pits, preparatory to rolling, an immense bridge crane is employed (shown on page 455), which is made on the rack and pinion order. The lifting hooks of this type of crane are attached to a vertical plunger with rack teeth that mesh into pinions which are operated by electric power. There is also a counterweight attachment which adds to the novel mechanical features of this crane.

In one of the other mills is still another type of electric traveling cranes for serving the soaking pits. In this the lifting is done by a pair of vertical screws driven by a motor, and this is capable of lifting enormous weights. There are also about the shops numerous other electric cranes and hoists, but these are not of special interest. Improvements in the line of braking mechanism for the larger lifts are contemplated.

POWER HOUSE.

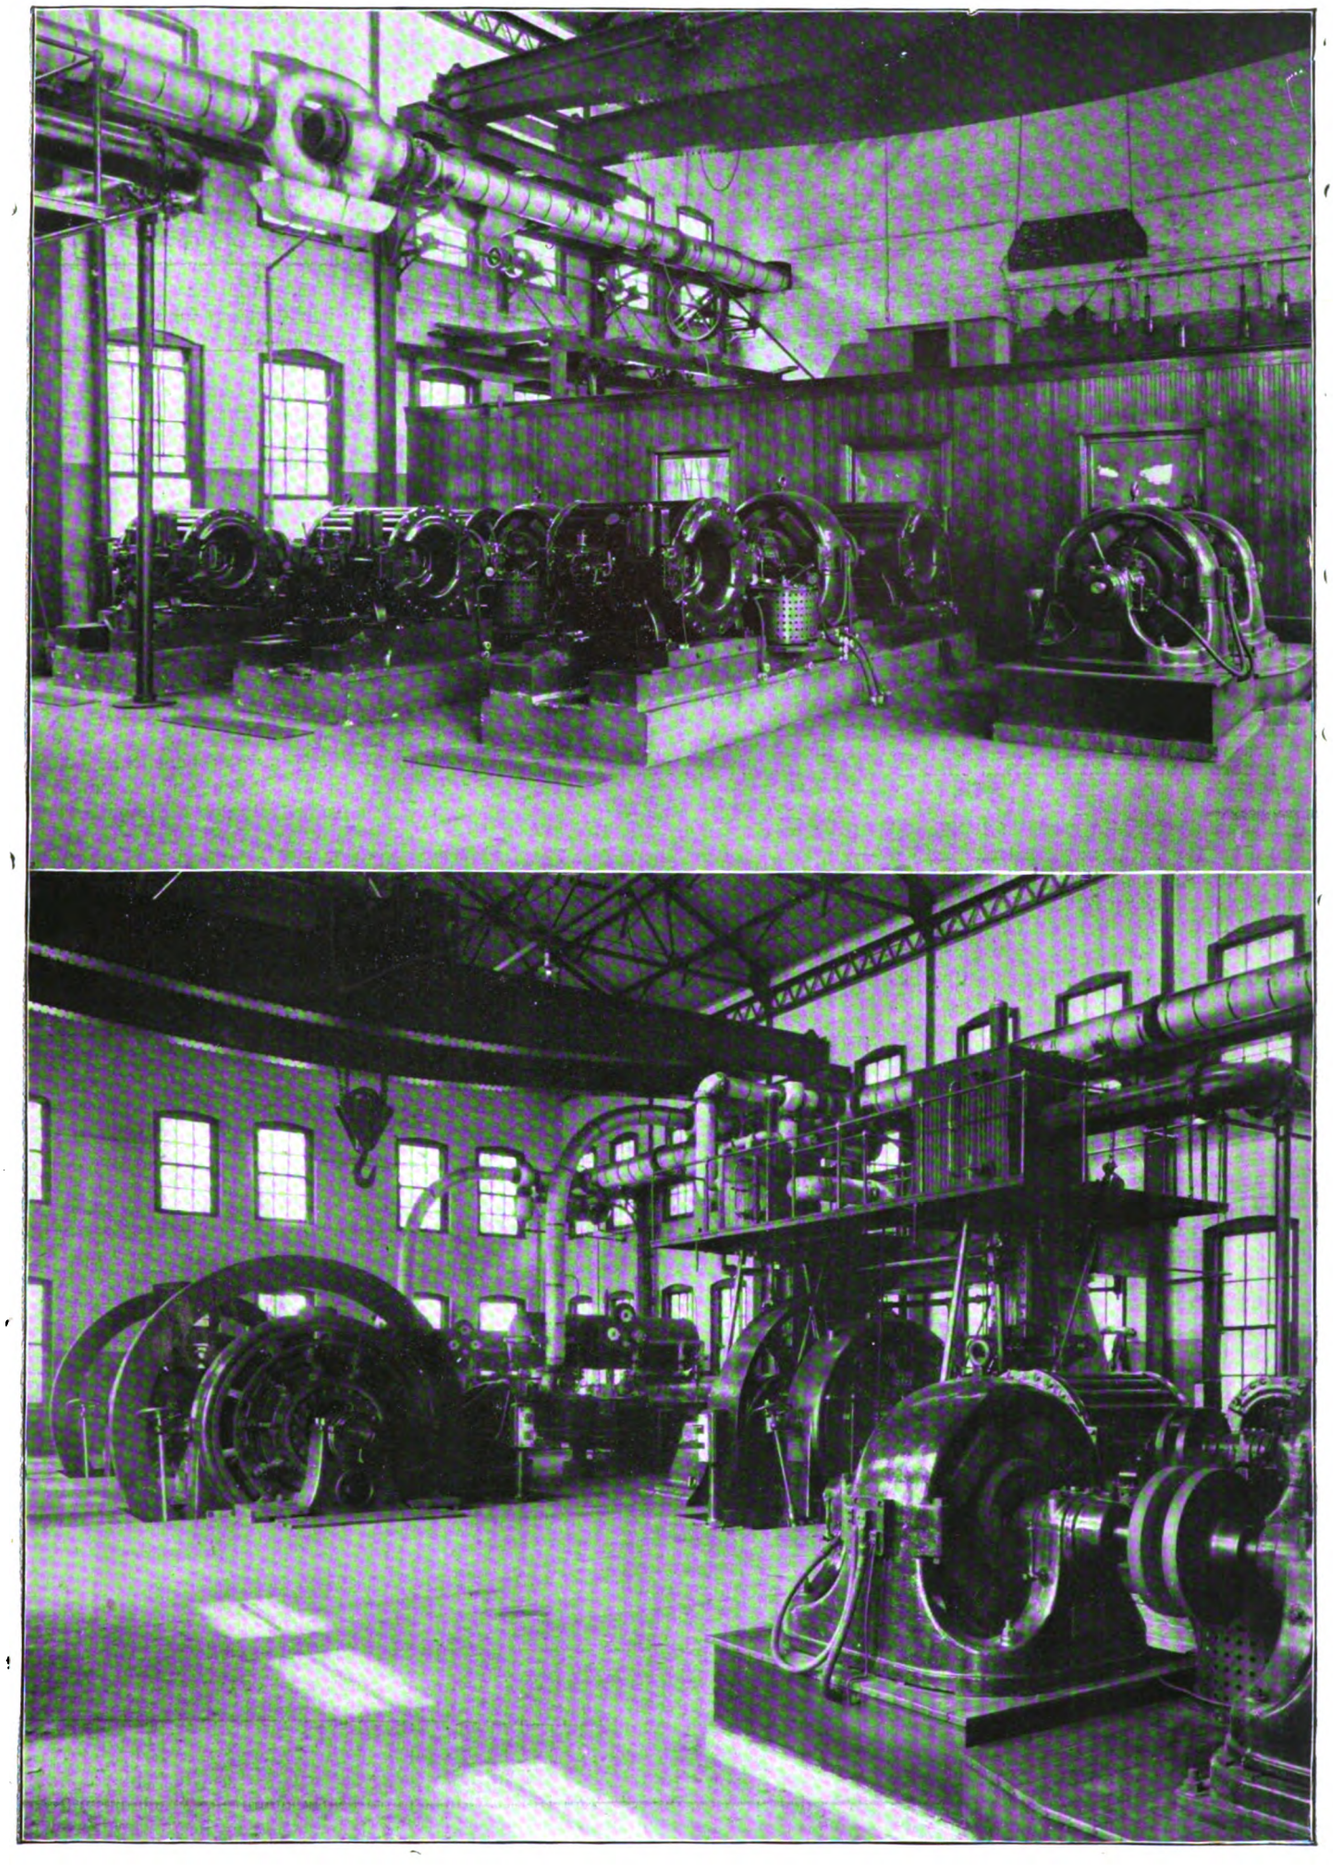
The current for operating the various motors, and for lighting, is generated in a single plant recently constructed and which takes the place of three plants formerly required.

The interior of the power plant is shown on page 459, from which it will be seen that several types of generating units are employed. There is one pair of tandem compound Porter-Allen engines, each direct-coupled to a 400-kw. Westinghouse generator, which delivers a 250-volt direct current. There is also a 600-h. p. vertical cross compound McIntosh & Seymour engine direct coupled to a 300-kw. Westinghouse generator.

A very interesting feature of the power plant is the method of operating the lighting machines. The six arc machines are of the T.-H. type and are driven in pairs by a 100-h. p. Westinghouse motor, through flexible couplings. These motors are driven from the power generators above described. They require less attention than would engines and are more economical from the fact that large engines are employed for the initial power. There is also a 60-kw. alternating machine for the incandescent lights. The lighting equipment consists of 300 Standard arc lamps, 150 enclosed arcs and 1000 incandescent lamps.

The repair shop for the electrical equipment adjoins the engine room, in which an electric motor supplies the power for operating the gear cutters, engine lathes, planers and other tools required in the repair department. In this department is also an electric hoist for removing supplies from the basement directly under the repair shop; there is also a 20-ton electric traveling crane in the engine room.

It is estimated that a saving of 50 per cent. in the cost of power is effected by the use of motors in the various locations above described over that of steam power formerly employed.

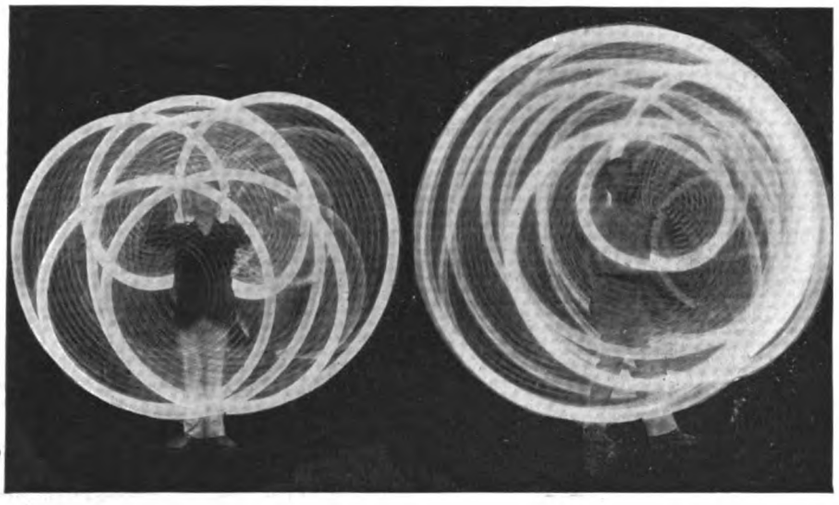


## A LIVE ELECTRICAL CLUB.

Nearly 150 young men attended the first fall meeting of the Y. M. C. A. Electrical Club recently held in the parlors of the Central Department of the Young Men's Christian Association of Chicago. In view of the fact that interest in industrial education is rapidly growing, this meeting is a significant one. The young men who are members of this club are engaged in electrical or allied pursuits during the day, and the club was formed by them more than two years ago for the purpose of securing facilities for an electrical education. It seems strange that in a city the size of Chicago there should be no provision made for the education of electrical apprentices, but the fact is that, outside of the efforts being made by this Y. M. C. A. Electrical Club, there is no opportunity offered to young workmen eager to improve their condition by evening study. As the work of this organization is an attempt by the young men themselves to fill a gap in our educational system which is so elaborate in nearly every other direction, it is a movement which should attract more than passing notice. The club is not a fad, but has behind it a record of over two years of solid growth, and its plans for the coming season have been developed from a recognition of the actual needs of the members. It has among its numbers several young men who are rapidly rising to positions of responsibility, and who owe much of their success to benefits secured through club work.

Last year the association management set aside a room to be used as an electrical laboratory, and the club collected nearly $1,000 worth of apparatus from various manufacturers as a laboratory equipment. It has been the aim of the club to secure one or more samples of the new electrical devices put upon the market from time to time, and to instal them for use in the laboratory, and it is under obligations to many manufacturers, who have kindly contributed to carrying out this idea. At the present time the club is interested in raising a fund of $2000 for the purchase of a complete set of practical testing and measuring instruments, and a number of very generous contributions from some of the large electrical interests of Chicago have already been received. This laboratory equipment is not opened indiscriminately to the use of the members, but is used in systematic study in the electrical classes, which are carried on under the international system so thoroughly developed by the Y. M. C. A.

Under this international system it is possible for every association in the country to do the same work in its evening classes. The prospectus of a course of study to be followed in both the elementary and advanced electrical classes has been carefully prepared by Prof. E. J. Houston of Philadelphia, and the printed examinations at the end of the year's



Digitized by Google

Interior Views of the Power Plant of the Illinois Steel Works.

Digitized by Google

work are of such high standard that the holders of certificates issued by the international committee are given credit for the work done in the classes in more than 100 universities and technical schools. In the international examination last year, three students in the elementary electrical class of the Chicago

ELECTRICALLY LIGHTED INDIAN CLUB EXHIBITION BEFORE THE CHICAGO ELECTRICAL CLUB.

department secured a grade of 100%, and two students in the advanced class stood 98% and 99% respectively, while the display by these classes at the international educational exhibit held at Grand Rapids, Mich., was given the highest award of merit. The electrical club naturally feels proud of the record made by the classes which are conducted as part of its work. For three years these classes have been in charge of Mr. Geo. A. Damon, electrical engineer for the Arnold Electric Power Station Company.

In addition to the classes in electricity, and as a result of some preliminary work along this line last year, there will be two courses offered this season in electrical laboratory work. These courses are intended to illustrate the principles taught in the classes and will be of a thoroughly practical nature. The club has been fortunate in securing the services of Mr. W. B. Hale, electrical engineer in charge of the testing laboratory of the Western Electric Company, who will have charge of the laboratory, and who brings into the work a rich experience in commercial testing methods. Mr Hale will be assisted by Mr. Fitzhugh Taylor, a senior student in the Armour Institute of Technology, and president of the club.

In addition to the classes, which continue for 25 weeks, beginning Oct. 1st, the club work includes an interesting program of meetings held upon the last Friday evening of each month during the period occupied by the classes, and every Friday evening for two months after the class work closes in April. These programs include excursions, practical talks and open discussions upon live topics. Last year the discussion on "The Electrical Business" was published in a number of technical papers, while Mr. A. V. Abbott's talk on "Wireless Telegraphy" filled the association hall with a paying audience. One of the most popular entertainments given by the club was that including the electrical spectacular effects originated by Mr. Geo. W. Patterson, who is a member. Mr. Patterson is the originator of the electrically lighted Indian clubs, and as he is an adept at swinging them, the graceful serpentine movements which he produces in a darkened room with the clubs illuminated by constantly changing multi-colored miniature incandescent lamps produce an effect which has been aptly termed "a new school of pyrotechnics." The illustration on this page shows a reproduction of a photograph taken by means of the light of the lamps alone, the small circles indicating the path of the miniature lamps, while the larger and brighter arcs mark the curves traced by 100-candle power lamps on the extreme ends of the clubs. Many other classes in the sciences, drawing and mathematics which are necessary for a complete electrical education are offered in connection with the evening college department of the association. These classes, together with those in other branches, make the association building the headquarters for nearly 1000 separate students during the evenings of the winter months.

This year's program includes an open discussion upon the subject "How to Become a Successful Electrician," and the book written by Sloane upon the subject will be taken as a basis. Last year the experience meeting upon "How I Got My First Electrical Job," was so successful that another experience meeting will be held this winter, the topic being "What I am Doing in Electrical Work." These experience meetings and open discussions bring the members closer together, and, in a number of cases, have been the means of some of the members securing a higher grade of employment. The "Members' nights" are always beneficial, as these evenings are taken up by papers prepared exclusively by the members upon subjects with which they are familiar, and it is one of the objects of the club to develop facility of expression in technical discussions.

The club is now planning to entertain its friends shortly with an "Evening with Statical Electricity." For this purpose they have interested Mr. E. E. Jewel, the president of the McIntosh Battery & Optical Company, who will display a sixteen-plate static machine, which is said to be the largest machine of the kind ever built. In addition to the striking phe-

MEMBERS OF THE Y. M. C. A ELECTRICAL CLUB OF CHICAGO

Digitized by Google

nomena made possible by this monstrous machine, a very complete collection of beautiful Geissler tubes will be shown, while the X-ray effects made possible by the intense power developed by the sixteen-plate machine promise to be interesting.

An annual banquet is held each year during the Christmas holiday season, as the classes have two weeks' vacation at that time. At this banquet at least a dozen toasts are given by different members and an artistic menu card is usually a feature.

The club has the nucleus of a circulating library, to which important additions will be made this winter. This library is not intended to be complete, as only practical books which are suitable to the uses of the club members are secured, and it is remarkable how few books there are published of a thoroughly practical nature. In order to use this library intelligently the meeting in October will be a discussion of a paper upon the subject "What to Read and How to Read It." This meeting will be followed six months later by the library night, at which time it is proposed to have ten members review briefly some book in the library which they have read.

It will thus be seen that the work of the club is comprehensive, and is of such a nature as to furnish something of continued interest to each of its members. The three objects of the club as set forth in its short constitution are: Mutual improvement; entertainment of friends, and to augment a spirit of fraternity among association members. Judging from the results already obtained, the club is successfully carrying out all of its objects, and its methods might well be followed by clubs organized in a similar manner in many of the larger cities.

## ELECTRIC POWER IN A SHIP YARD.

The part which electricity plays in the building of the modern ship, as shown at the works of the Chicago Ship Building Company, embraces nearly every one of its ordinary applications, from lighting to telephone service, with the exception of heating. In the application of motors to the details of ship building it is believed that the Chicago yard is in advance of all other ship building plants in existence. This is doubtless due to the fact that the Chicago works are of recent establishment and purely modern design.

In order to understand the various uses of electricity at this point some idea should first be obtained of the character and extent of the yards and the work done there. The works of the Chicago Ship Building Company are located at 101st Street and the Calumet River, in Chicago, in the part of the city known as South Chicago. In building its plant the company has had one great advantage over most older establishments. The whole yard was laid out in the beginning for a complete plant. All additions made since the start have, therefore, been according to the original general plan. The yard is on this account more systematically and conveniently arranged than most yards that, starting on a small scale, have had their facilities extended by a process of gradual addition.

The Calumet River, at 101st Street, being only 225 feet wide, the Chicago Ship Building Company's yard had to be laid out to build ships on a level keel and launch them sidewise. Three slips at right angles to the river were dredged out and docked, giving six building berths. These building berths are kept in use almost continually. At present there are four ships in process of construction in the yard and one has been delivered within the last few days.

Two steam locomotive cranes run about on the tracks and do invaluable work in loading and unloading material. Besides the full gage tracks a complete system of Hunt narrow gage railroad runs from the plate and channel shops to the building berths.

In this plant some of the largest and handsomest vessels on the Great Lakes have been constructed. They are all built of steel, according to the most approved methods of modern ship building, with certain peculiarities and specialties of the Chicago Ship Building Company in addition. As a rule the largest size freighters are built, but some handsome passenger steamers have also been turned out by the company. Notable among them are the steamships Manitou and Illinois, the pick of all the vessels running regularly on Lake Michigan.

The part which electricity takes in building these great lake vessels begins at the power house. This building is situated almost exactly in the center of the big twenty-five-acre tract, and supplies every part of it with light and power. It is made of iron, thoroughly fireproof, and contains the boilers, engines and dynamos, as well as considerable air-compressing machinery.

The boilers are six in number. Two are Berry boilers of 300 h. p. each. The other four are of the Scotch marine type, of 500 h. p. each. They are located in the west wing of the power house, with the usual feed pumps, etc. The stack is of steel and is small, forced draft being used. The engine room takes up the greater part of the power house. It contains two large air compressors for the pneumatic service of the yard, the steam and electric units and the switchboard.

The main generating set consists of a 150-kw. Elwell-Parker dynamo, connected directly to a 200-h. p. compound Willans engine. For night service a 40-h. p. Edison dynamo belt-connected to a Rice engine is used. A spare General Electric dynamo of 50 kw. capacity, driven by a compound Lake Erie engine, is held in reserve for accidents.

The switchboard is necessarily simple and ordinary. Nine lighting and power circuits run out from the board to all parts of the yard, the largest wires used being 350,000 cm. in cross sections. The entire system, light and power, is run at 220 volts, direct current. There are thirty-five arc lights in use and 400 incandescent.

The power circuit has on it eighteen motors in various parts of the yard, aggregating over 300 h. p. The nearest is a few feet away from the switchboard, and the farthest is in the dry dock shop, over 2000 feet away. These motors range in size from 5 h. p. to 50 kw., and vary in type almost as widely. The variety of uses to which they are put is interesting.

The nearest motor to the switchboard is a 15-h. p. C & C. It is used to give the forced draft in the boiler room. In the blacksmith shop the most recent application of motors has been made. This is a new structure of iron and glass 60x100 ft. in floor area and 40 ft. high. It is equipped with the down draft system of the Buffalo Forge Company, which gives a blow and suction both at each forge. A 25 h. p. Crocker-Wheeler motor is belted directly without the intervention of line shafting to both blowers. Sixteen forges are thus supplied with air pressure, and have their gases removed.

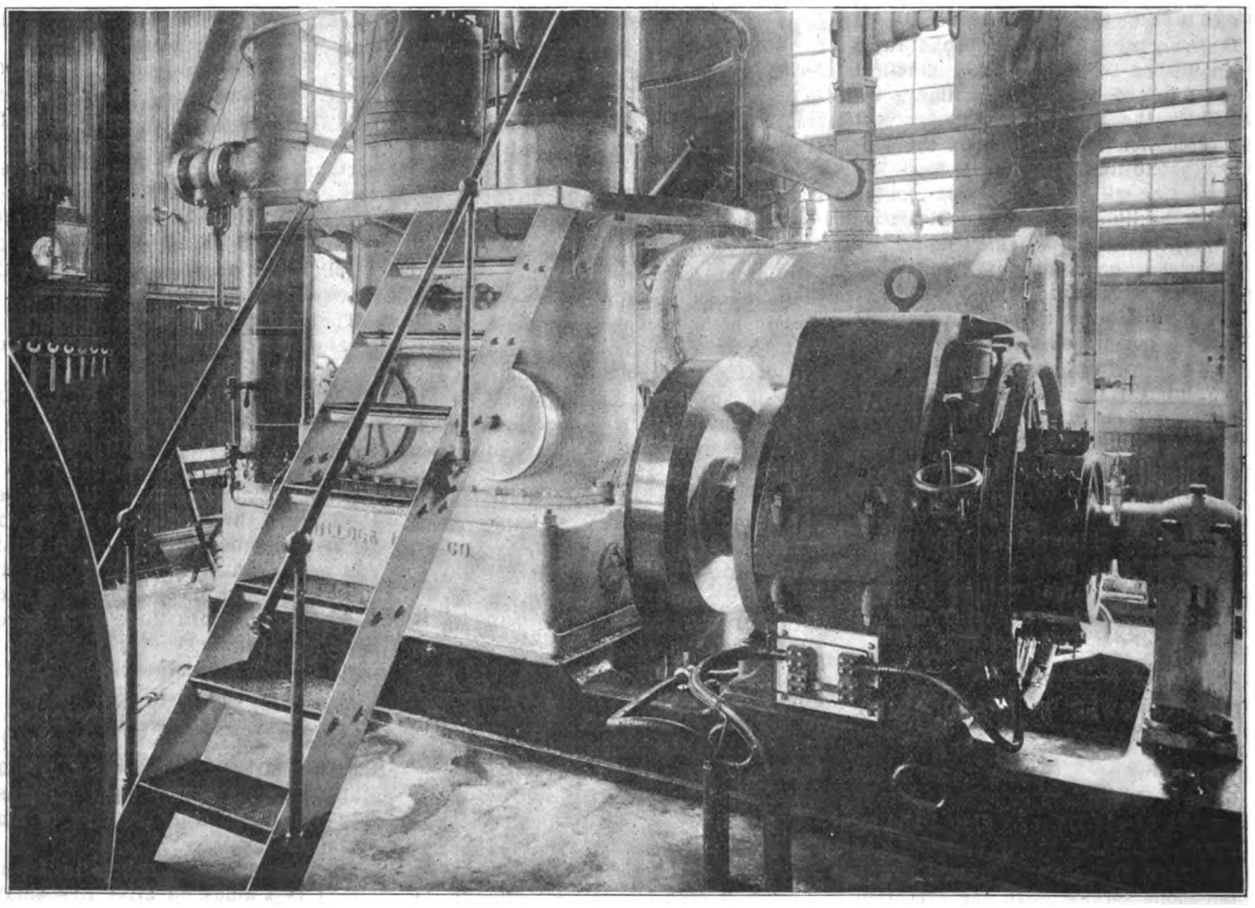
The machine shop is the scene of the greatest use of electric motors in the Chicago Ship Building Company's yard and its owners consider it to be the finest specimen of a marine engine shop in the United States. It is constructed entirely of steel and glass, a large quantity of the latter material being used. It is probably the lightest shop of its kind in the country, and has been found cool in summer and easy to heat in winter. The main portion of the shop is 60 ft. wide and 60 ft. high to the roof trusses. There are no galleries, the work being done on the main floor, which is under the direct supervision of the foreman in charge. On either side of the central portion of the shop is a 30-ft. wing. In area, therefore, the shop is really 200 ft. long by 120 ft. wide. There are only eight columns in this space to obstruct the view or hinder operations.

The uses of electric motors in this shop are of two kinds, to drive line shafting and to run separate tools. Besides these, there is a traveling crane which is motor driven. The line shafting is located in the wings of the shop and drives the smaller lathes and tools. An Elwell-Parker 20-h. p. motor placed on a platform in each wing is belted to the shafting. The direct driven tools are in the main portion of the shop on the floor. The entire center portion is spanned by the electric crane, which is of the 25-ton size made by the Brown Hoisting Company. This is driven by three Elwell-Parker motors. The columns of the shop were made heavy enough to stand two 25-ton electric cranes, and undoubtedly the second one will be installed before long. Brackets were also put on the main columns about 25 ft. from the floor, on which to support a smaller crane girder. This is intended to carry a

Digitized by Google

10-ton crane under the main cranes, which will be called on to do most of the light lifting in the shop.

The machine shop tools driven by motors are of particular interest, owing to their large size and remarkably successful operation. They include lathes, drills, planers and milling machines. A 72-inch screw cutting lathe made by the Niles Tool Works is fitted with a 5-h. p. Elwell-Parker motor. The feature of the machine-driven tools, however, is the Niles Tool Works horizontal boring mill. This is one of the largest tools of its kind in the country. It has proved remarkably handy on account of the variety of work it will do and the number of operations which can be performed at one setting of the work. This tool is driven by a 5-h. p. Crocker-Wheeler motor, which will give a wide speed variation to the drills. A vertical boring mill made by the Pond Machine Tool Company is run by a 10-h. p. General Electric motor at a constant speed.



In the plate and channel shops, the various machines are all driven from line shafting, turned by electric motors. Two of the latter are used, one at either end of the building. They are put at the level of the line shafts on platforms, and are belted to the shaft pulleys. They drive, through the shafting, the punches, shears, rolls, reamers, planers and counter sinks used to handle the plates for the ships' sides, and the angle shears, punches and bending machines used on the angle irons. In the channel shop there is a powerful bending machine, built by William Sellers & Co., which will bend cold a 24-inch I beam between supports 4 ft. apart. All deck beams for the ships are cambered cold on this machine.

The joiner shop has the largest electric motor used in the yard. It is a 50-h. p. General Electric machine, and is used to drive the entire line shafting for the building. It is placed on a platform at one end of the building, and is belted to the shaft.

The dry dock is the largest on the Great Lakes. The extreme length is 540 ft. and width 100 ft. Sixteen feet of water is given over the mitre sill at ordinary river depth. The dock is emptied by steam centrifugal pumps with a capacity of 50,000 gallons a minute. A small oil burning plant is provided for the purpose. Beside the dock, and really forming part of it is the repair shed, or house, where the repair work on vessels is done. A 30-h. p. Elwell-Parker motor drives the line shafting in the building, turning the various lathes, saws and tools. It is connected in the same manner as the other motors driving line shafting. This motor is 2,000 ft. away from the power house.

Up to the present, the principal work in the building berths has been done by a pair of steam traveling cranes and the locomotive cranes. Now, however, 25-ton electric cranes are being installed over the berths, two for each of the four middle berths. They are made by the Brown Hoisting Company and fitted with Elwell-Parker motors. They are a great improvement in speed and convenience over the steam cranes.

On the dock at the river front stands a huge steel sheer with legs 100 ft. high. This is used for stepping masts and lifting heavy material, including the engines, into the ships after launching. It has a capacity of 100 tons. There are three legs, the back one being operated by a horizontal screw to throw the head of the sheer in and out. This screw is driven by a steam engine, but is soon to be operated by an electric motor. The sheer was made in the yard.

THE DIRECT-COUPLED WILLANS ENGINE AND ELWELL-PARKER DYNAMO OF THE POWER STATION OF THE CHICAGO SHIPBUILDING COMPANY.

In the finishing of the vessels the electric work is most important. Small marine electric lighting plants are now put in every ship of size, even if it is to be used only for freight. This work, as well as the general electrical supervision of the yard, is under the charge of C. C. Mattison, the electrician of the company. As high as 40 men are frequently employed in the wiring gang. A representative sample of the work done is in the Maunaloa, a large steam freighter, is 460 ft. long, deliv-

Digitized by Google

ered to the Minnesota Steamship Company a few days ago. The electric plant consisted of two 10-k.w. General Electric marine type dynamos driven by high-speed engines. The switchboard, made by the Chicago Ship Building Company, is of slate, with Weston instruments and switches made in the works. Ten branch circuits run from the board. The wiring is all in moulding. The lamp sockets are made watertight both in the engine room and hold and above deck. The work is carried on in a construction and repair shop occupying a portion of the storehouse.

The telephone system of the works is one of the handiest things on the grounds. It was installed by the American Electric Telephone Company, with its apparatus. A 25-drop switchboard is in use, located in the office building. It has 20 telephones in the various buildings of the yard connected to it.

## THE "SAME CIRCUIT" METHOD OF INCANDESCENT LAMP PHOTOMETRY.

In the measurement of the candle power of incandescent lamps it is customary to use as a working standard of comparison at one end of the photometer some form of standard oil burner or a previously tested incandescent lamp carefully maintained at its rated voltage. A simple kink of photometric work known as the "same circuit" method, which does away with the bothersome oil burner and eliminates any calculation involving voltage, has come into extended use by lamp manufacturers, but does not as yet seem to be generally appreciated and used as it might be by central-station men. It is based on the principle that if two incandescent lamps are supplied from the same circuit, and are burned at about the same brilliancy, their candle power will increase and decrease in the same proportion with changes of voltage and their relative candle power will remain constant.

If then a working standard is mounted on one end of the photometer bar and the lamp to be tested at the other end, and both are supplied with current from the same source, even if the voltage fluctuates, the candle power of both lamps will go up and down together and the relative candle power or the position of the photometer screen over the scale will remain constant. Obviously no accurate voltmeter measurement is needed in this method of working.

The connections when working in this way are shown in Fig. 1, where S is the standard lamp and T that under test, connected across the same leads supplied from a source of power at the left. If this source of power is of much higher voltage than that of the lamps—as it is likely to be in central stations having a considerable drop in their feeders—a rheostat should be inserted at R to cut down the pressure to avoid deterioration of the standard as well as to bring the two lamps to about their normal voltage. Care should be taken in this case not to turn off the lamp, T, as the reduced drop in R would raise the pressure on the standard, S. Wherever a pressure within two or three volts of that for which the lamps are rated is available, no resistance is necessary.

A voltmeter may be inserted, as shown, in order to have the lamps at about their rated voltage, since, if the voltage is raised considerably above or lowered con-

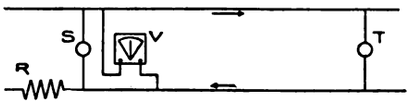


FIG. 1.

siderably below normal, the candle power of the lamp under test might not go up or down exactly the same percentage as that of the standard lamp unless both filaments were of the same physical characteristic, and particularly possessed the same ratio of graphitic to base carbon. Over considerable fluctuations of voltage, however, such as 3 or 5 per cent., the candle power of all lamps varies in so nearly the same proportion that the adjustment of the voltage, with any care whatever, is not necessary. The adjustment of the lamps to normal candle power by the eye is quite sufficient, so far as accuracy of the measurement is concerned. The meter may, however, be useful to prevent overburning the standard. Obviously the reading of this voltmeter does not enter into the calculation of the candle power which is read off immediately from the scale.

When it is desired to test lamps all of one rated voltage, the system is obviously most simple, and when lamps of different voltages must be tested the only addition necessary is a number of working standards, one for each different voltage. If it is not desired to keep in hand and calibrated so many different working standards, one may be made to serve over a small range of voltage by means of an adjustable photometric scale. For in-

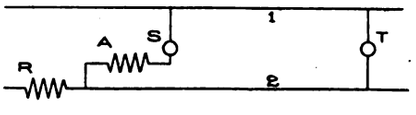

FIG. 2.

stance, if the working standard gives 16 candle power at 112 volts, 110-volt lamps may be compared with it by sliding the scale to favor the lamp under test by the difference between the candle power of a lamp burned at 110 and 112 volts. In the same way the 112-volt standard may be used for testing 114-volt lamps by sliding the scale in the other direction, i. e., to favor the standard, to a point determined by a graduated set of marks on the instruments. The tests may be carried out as explained above with a pressure on the lamps equal to or somewhat less than that at which the working standard is rated and either steady or fluctuating.

To reduce the number of standards required for a photometer designed to measure a general line of lamps from 50 to 250 volts, another modification may be made by inserting a resistance in series with the standard lamp alone. The arrangement of the circuit in this case is shown in Fig. 2, where the added resistance is represented by the letter A. This resistance should be made adjustable and may be calibrated so that even in this case no voltmeter measurement is necessary. An explanation of the proper value of this resistance is best given by taking a specific case. Assuming that the lamp, S, gives 16 candle power at 100 volts, and T is rated at 110 volts, the resistance, A, should be sufficient to absorb just 10 volts and give S 100 when the voltage between wires 1 and 2 is 110. The two lamps will then both receive their normal voltage when the difference of potential between the wires, 1 and 2, is 110 volts, and will rise and fall in candle power equally when the pressure varies. If the resistance of A is increased sufficiently to give a drop of 12 volts out of 112, it adapts the instrument to measure lamps of the latter pressure. Thus the photometer may be made to measure lamps rated at any pressure above that of the standard, in this case assumed to be 100. The resistance of A may be made adjustable with a contact traveling over a scale direct reading in terms of the voltage to which the resistance adapts the standard lamp so that when it is desired to measure lamps rated at 114 volts, for instance, the contact is set opposite the 114-volt mark, etc. The resistance should of course have a negligible temperature coefficient.

Portable photometers of extreme simplicity and light weight may thus be made and fitted with three standards, one for lamps of 55 volts or thereabouts, another for 110 volts or thereabouts, and a third for 220 volts or thereabouts. A description of such a photometer appears in the department of "New Apparatus and Appliances," in another part of this paper.

The "Same circuit" method should prove of the greatest value in central-station photometry where the simplicity of its apparatus and circuits, the absence of several simultaneous readings, the total elimination of corrections and calculations, and the ability to work over a considerable range of pressure, steady or fluctuating, should commend it for use in place of any other method.

**Another High Pressure Three-Wire System in This Country.**—The Narragansett Electric Light Company of Providence, R. I., is installing a three-wire distributing system with 450 volts between the outer conductors and 225 volts between each outer and the neutral. This is the second system of the kind in this country, the first being the well known Imperial plant in St. Louis, Mo., although a large number of such central stations are in service in England.

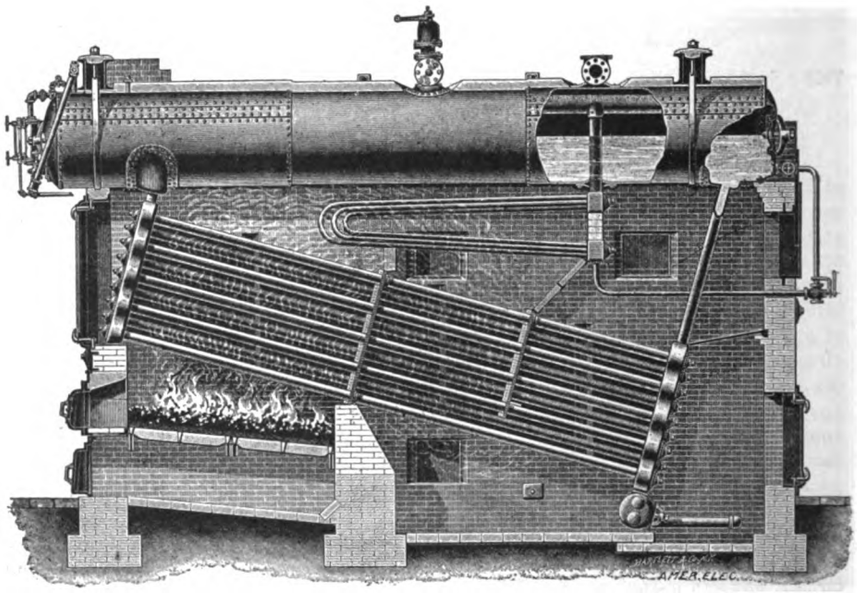
## NEW DEVELOPMENTS IN STEAM SUPERHEATING.

It has always been recognized that a great gain in the economy of the steam engine could be accomplished by superheating the steam supplied to it, and many attempts have been made in the past to develop commercially practicable apparatus for this purpose. These attempts were invariably unsatisfactory, owing to several difficulties, mainly the burning out of the superheating apparatus and the impossibility of lubricating the engines at the high temperatures of the superheated steam, so that finally all work in this line was abandoned as impracticable. Like many other great improvements in engineering the difficulties in the way of steam superheating have been to a certain extent removed by the increased skill now customarily found in firerooms and the improvements in materials and design of boilers and engines, so that the way is now apparently open for the successful use of superheated steam, and many engineers believe that in this direction the next great advance in the economy of power production will be made.



When water is evaporated into steam, as in the ordinary boiler, the fine bubbles of vapor that pass upward and are disengaged at the surface, are, of course, of exactly the same temperature as the water which they leave, any higher temperature on their part being impossible, as they would be instantly cooled by the water around them. This temperature is, of course, the boiling point of water at the pressure in the boiler, since the water cannot exist in the liquid form at a higher temperature at that pressure. The only way to obtain steam of a given pressure at a higher temperature than that corresponding to its boiling point at that pressure is to pass it, after it has been entirely disengaged, over independent heating surfaces, through which it can be heated up to any practical temperature desired.

The advantages of superheated steam are two, one of which may be termed theoretical in character and the other practical. The maximum theoretical limit of economy of an ideal engine is known to be proportional to the difference between the temperature of the entering steam and that of the exhaust. If an engine works between a boiler pressure of 100 lbs. and the atmosphere, the temperature of the incoming steam, if not superheated, is about 337° F., and that of the exhaust is 212° F., giving a difference between the two of 125°. If now the steam is superheated 125° at the same pressure of 100 lbs., the difference between the temperature of admission and exhaust will be 250°, and the steam consumption per horse power hour will be theoretically only half as great, although practically not quite as good results can be obtained. To attain the same temperature of admission without superheating would require a boiler pressure of nearly 400 lbs. to the sq. in.

In actual steam engine practice another great advantage is found in the reduction of what is called the initial condensation. When ordinary steam enters a cylinder which has during the previous stroke been open to the atmosphere or condenser, the iron walls, cylinder-head and piston are considerably cooled by the low temperature of the previously outgoing exhaust steam. A considerable amount of the incoming hot steam under pressure is immediately condensed into water by these cooled walls. This water is later re-evaporated into steam when the pressure falls off and the exhaust port is open, this steam passing away from the cylinder without doing any work whatever. If highly superheated steam is used the cool walls of the cylinder are heated up when new steam is admitted without condensing any water upon them, the steam being cooled somewhat but not to a low enough temperature to cause its condensation. Thus no water goes through the engine in the liquid form and the economy is greatly improved.

There are two radically different methods of generating superheated steam. One is the use of a boiler pressure considerably higher than the engine pressure, the steam being wire drawn on its way from the boiler to the engine. The heat liberated by the friction of the steam in passing through the reducing valve tends to superheat it at the lower pressure. It is quite customary in European torpedo boat and other high pressure steam practice to generate the steam at about 300 lbs. pressure and reduce it to 250 lbs. or so before it enters the engine. This practice reduces initial condensation, as pointed out above, although no great amount of superheat can be obtained in this way without enormous boiler pressures, but it does not tend in the slightest to obtain the first or theoretical advantage pointed out above, viz., an increased range of temperature; in fact, the initial temperature is somewhat lowered by the wire drawing process. The reduction of the steam pressure is thus, outside of the reduced initial condensation, a positive disadvantage, for the same reason that a throttling governor, for example, is a disadvantage as compared with an automatic cut-off mechanism.

The only other way to generate superheated steam is to take the saturated steam delivered by an ordinary boiler and pass it over independent heating surfaces, either in the boiler setting itself or arranged like economizers in the flue between the boiler and stack or heated by independent furnaces. The last arrangement is rarely if ever used for reasons that will appear below.

THE BABCOCK & WILCOX METHOD OF SUPERHEATING.

The location of superheating tubes in the flue receiving the hot gases after they have left the boiler requires a very great amount of superheating surface to accomplish any results, especially if the boiler is an efficient one, since the gases at this point should be thoroughly cooled to a temperature of at most about 500 or 600° F. It is obviously a radically wrong principle to pass the gases, when hottest, over the colder surfaces of the boiler, and then, when the gases become cool, to attempt to extract heat from them through the hotter surfaces of the superheating apparatus. Theoretically, the superheaters should receive the hot gases first from the fire, and after they have become cooled somewhat the gases should then pass on to the tubes of the boiler proper, where they could be cooled down to the lowest possible limit. Practically this is utterly unattainable, as a flame direct from the fire would immediately burn out superheating tubes, which, unlike boiler

Digitized by Google

tubes or heating surfaces, are not constantly cooled by the contact of water.

A compromise between the theoretically ideal arrangement of the superheater next to the fire and the practical disadvantage of the same has been during the last few years incorporated in many boilers by the foreign Babcock & Wilcox Company, and is now being introduced into this country by the American house of the same name. The arrangement of the parts is shown in the accompanying vertical section of the boiler.

It will be seen that the hot gases and flame pass up as usual across the complete series of tubes and then strike the superheating tubes before they again return downward, recrossing the water tubes on their way to the flue. Thus the intense heat of the fire is tempered somewhat before the gases reach the superheating surfaces, where they are at a temperature of perhaps 800 to 1000° F., the gases afterwards being thoroughly cooled to as low a point as economy dictates by their repassage twice through the water tubes of the boiler.

The superheater consists, as shown, of a series of U-shaped tubes expanded into wrought steel headers or manifolds similar to those of the boiler proper. Opposite the ends of each group of 4 tubes in the header is a handhole cover. Steam is received into the upper header through two large pipes coming down from a perforated horizontal "dry pipe" placed in the upper part of the steam drum. The steam then flows through the tubes of the superheater to the lower header, which delivers it into two pipes, one to either side of the boiler, which convey it to a flanged tee shown just above the superheater, from which it flows through the usual piping to the engines. By this arrangement the temperature of the hot gases is, as noted above, reduced so that there is no danger of burning out the superheater while steam is flowing, and the harder the boiler is worked the hotter are the gases flowing over the superheating surfaces, so that the combination is practically self-regulating as to the degree of superheat.

The only risk of burning out is when the fire is pushed and no steam is being delivered to the engines. This occurs, as a rule, when steam is being raised hurriedly from cold water. To provide for such times a pipe runs from the lower part of the steam drum to the under side of the superheater and is provided with valves behind the boiler. By opening these the superheater is flooded and made a part of the steam generating surface. These valves should, of course, not be opened while steam is being drawn from the boiler, or water will be delivered to the engines. The lower valve is made three-way, so that the superheater may be drained before steam is turned on.

Many tests have been made with this device in various parts of Continental Europe which show well the economy to be obtained and the advantage of superheated steam in eliminating steam pipe condensation and delivering perfectly dry steam to the engines. The tests show as a rule that the steam consumption is reduced by superheating from 10 to 25 per cent., the greatest gain being effected in simple engines of low speed, and otherwise most wasteful through initial condensation.

## Among our Foreign Contemporaries

**An Arc Lamp Coupling.**—All of the English electrical papers have recently described a new device for hanging outdoor arc lights by which awkward looking loops in the conducting wires need not be left to give slack for lowering the lamp. The arrangement is shown in Fig. 1, the coupling details being shown in the broken vertical section to the left. The supporting cable, which, as usual in English practice, rises through an ornamental pole, passes down through a bell or dome-shaped cap and carries at its lower end what might be called an attachment plug wired to the lamp. This, when the lamp is pulled up, enters a circular receptacle protected from the weather under a cap. The plug and receptacle contacts are concentric with the cable so that any twisting of the lamp does not affect them. When the lamp is lowered it is, of course, entirely cut out of circuit, eliminating any risk of shock. The springs for maintaining good contact are fixed to the plug so that they come down with the lamp and are accessible for renewal, the receptacle which stays up being of the simplest character, its contacts consisting simply of solid metal rings. The running of the suspension cable through the center of both plug and receptacle insures their concentric meeting when the lamp is raised. The receptacle shown is obviously for multiple work, the circuit being opened when the lamp is opened. It could, however, be adapted to series work by fitting it in such a way as to automatically short circuit the line when the lamp is lowered.

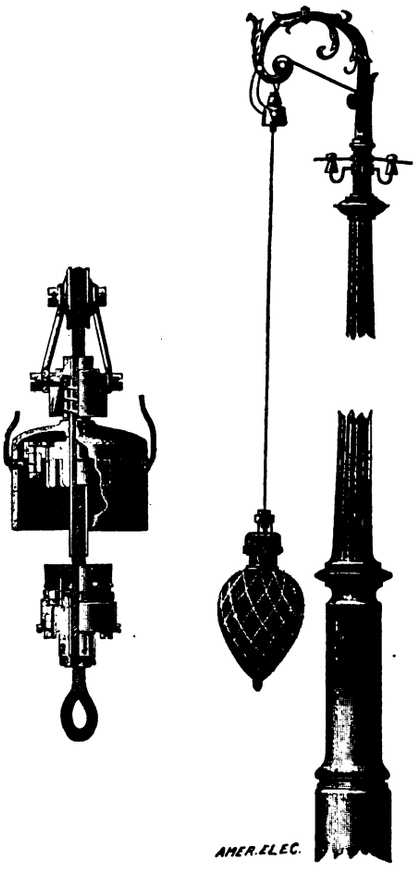


FIG. 1.—A COUPLING FOR DISCONNECTING ARC LAMPS WHEN LOWERED AND FOR AVOIDING SLACK CONDUCTING WIRES.

---

**An Automatic Cutout for Fallen Trolley Wires.**—In English electric railway practice it is customary to connect the feeders, which are almost universally underground, to the trolley wires through what are called feeder pillars. These consist of cast iron cases standing in the streets, resembling in appearance large hydrants, and containing lightning arresters, pilot wire terminals, switches by means of which the current can be cut off, and in some cases fuses or circuit breakers. An ingenious arrangement of a circuit breaker for use in such locations, designed to cut the current off instantly in case the trolley wire supplied through it is broken, is now in use on the Blackpool tramways and was recently described in the London "Electrical Review." The breaker is supplied with both shunt and series coils, the purpose of which is the same as that of the no voltage and overload release devices used on motor controllers in this country. The shunt coil is connected by means of a pilot wire to the end of the section of the trolley wire supplied through the breaker, and if this section of the trolley wire breaks at any point the shunt circuit is no longer energized and the breaker flies open before the trolley wire can reach the ground. The series circuit provides for the usual opening of the breaker on overload or short circuit. The only apparent objection to such a device is the fact that in case of failure of the current from any cause, as trouble at the power station, all the circuit breakers at all the feeder pillars on the lines will be opened.

---

**The Side Trolley.**—The overhead trolley system of most English street railways differs from that of American railroads in that no attempt is made to carry the trolley wire over the center of the track or, indeed, within 8 or 10 feet of it. The trolley wire being carried often away off

Digitized by Google

to one side, the trolley pole has to be capable of swinging out at an angle from the direction of the track, and the trolley wheel has to be swiveled so that when the pole is at a considerable angle the wheel itself can assume the direction of the trolley wire. The trolley has also to be made different from American standards in order to be worked on double deck cars, on which American trolleys would interfere with the passengers. Fig. 2 shows the construction of the Siemens pole, in which it will be seen that the pole proper does not start from a point near the roof of the car but springs from the top of a vertical standard 6 feet in height, which raises the pole so that it clears the passengers' heads. This standard is not necessarily centrally located on the car, but is generally placed off to one side. The trolley pole is fastened to a turntable which is supported on ball bearings on the top of the standard so that it is free to turn readily. The pole is forced up against the overhead wire by a long and powerful coiled spring entirely contained within the inner tube of the standard. Within the spring is the conducting cable, which must be insulated from the ironwork of the overhead system, since it is on a passenger deck. The conducting cable is attached to a collector ring at the lower end of the inner tube, the brush bearing on this collector ring taking the current to the motor below. The flexible cable passes up inside the pole to an insulated cap which appears in the enlarged view of the details, this cap being attached by a flexible cable to the harp carrying the wheel. This harp is also supported on ball bearings so that it is free to turn around a vertical axis and the cap on the end of the pole is loosely fastened so that if the wheel catches in the overhead wires it will be pulled off without wrecking the standard or the top of the car.

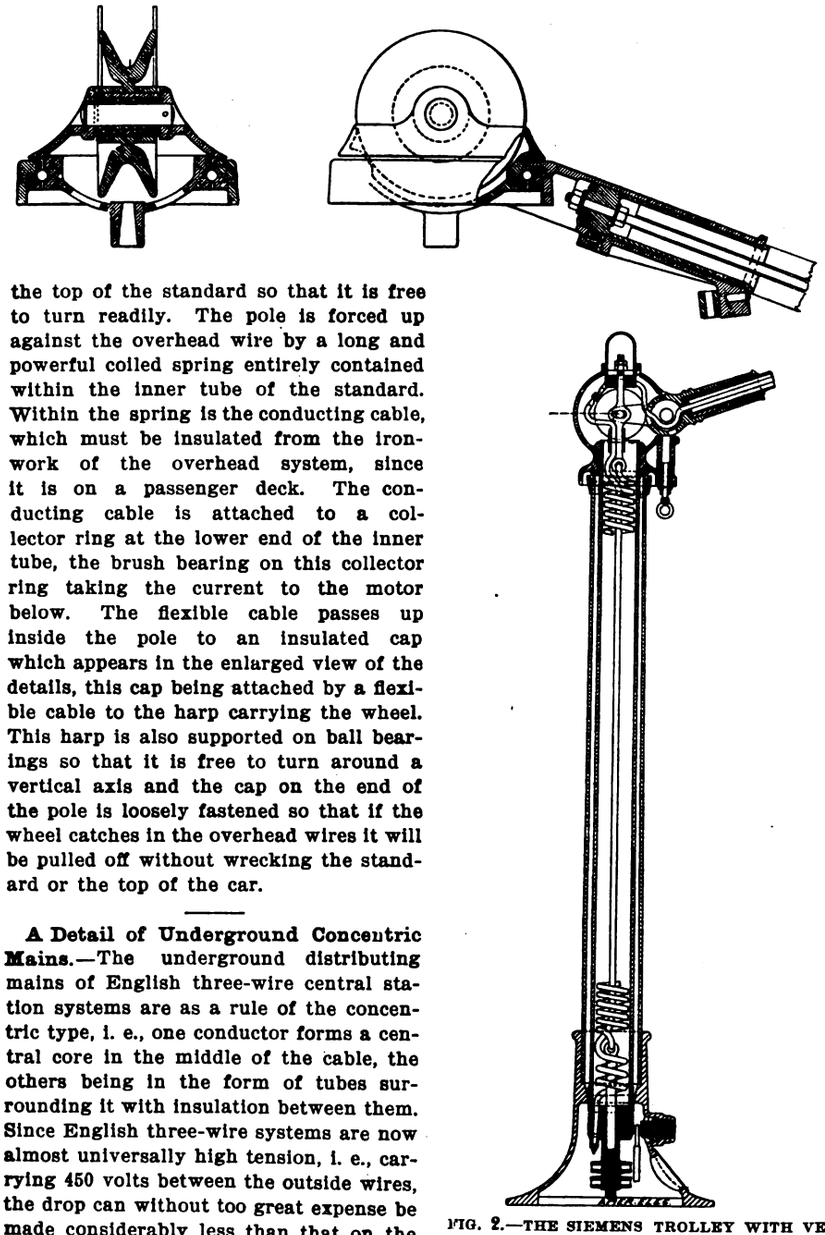

FIG. 2.—THE SIEMENS TROLLEY WITH VERTICAL STANDARD FOR DOUBLE-DECKED CARS AND TURNTABLE AND SWIVELING HEAD FOR SIDE TROLLEY WIRES.

---

**A Detail of Underground Concentric Mains.**—The underground distributing mains of English three-wire central station systems are as a rule of the concentric type, i. e., one conductor forms a central core in the middle of the cable, the others being in the form of tubes surrounding it with insulation between them. Since English three-wire systems are now almost universally high tension, i. e., carrying 450 volts between the outside wires, the drop can without too great expense be made considerably less than that on the 220-volt systems used in this country, and the loads therefore do not require to be so accurately balanced between the two sides of the system. It is in consequence customary to wire houses and other moderate-sized loads two-wire and connect them between one outer wire and the neutral. If the neutral is made the middle conductor of the three in the concentric cable, the inside conductor or core does not need to be tapped at the service branch boxes. If, however, all loads along one section of the mains were connected between the outer conductor of the cable and the neutral, this section would be badly unbalanced. To get around this difficulty there is installed on such systems at intervals what is called a reversing junction box, a plan of which is shown in Fig. 3. As may there be seen, the triple concentric cable coming in from the left is stripped in steps and laid alongside that coming from the right, and the outer conductor of one is connected to the central core of the other, the two middle conductors forming the neutral being connected to each other. In this way the positive side of the system is the outer concentric tube for one section, while beyond the next reversing box the negative side of the system is connected to the outer concentric conductor. Services branched off from the outer conductor and the neutral may in this way be balanced. The connections are made by pieces of gun metal sweated to the conductors. The joint is then taped over and the box is filled with compound. Fig. 4 shows a vertical section of one of the branch boxes for the services. A piece of the outer conductor is removed and the ends are connected by a gun metal connector so as to give access to the neutral. The two branch leads are brought up through ebonite bushings into a chamber in which fuses are mounted on a porcelain base. This chamber is covered by a glass window mounted in the cast iron frame, the whole being watertight. The box is located in a brick manhole with a cast iron cover so that it can be inspected and re-fused at any time.

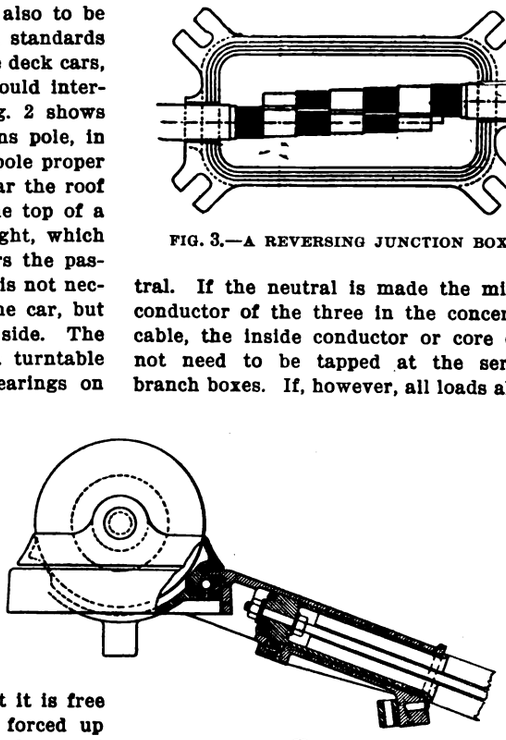

FIG. 3.—A REVERSING JUNCTION BOX.

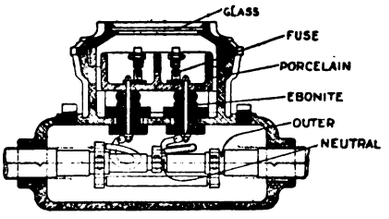

FIG. 4.—A SERVICE BRANCH BOX.

---

**Automatic Accumulator Disconnector.**—In order to automatically disconnect a battery of accumulators from a charging circuit, when they are fully charged, Dr. Peterson of Copenhagen has devised a comparatively simple apparatus which is described in the "Elektrotechnische Zeitschrift." The principle of the operation is that one of the batteries is hermetically sealed and has two bent glass tubes leading to the interior and containing mercury in the lower bend, so that when gases are generated in the cell they will press on one end of the mercury column, thereby changing its level; platinum wires are fused through these tubes in such a way that when the level is changed a certain amount, the circuit is broken by the mercury. The illustration, Fig. 5, shows the arrangement of the circuits diagrammatically. The right hand one of the two bent tubes containing the mercury, the lower ends of which pass into the interior

Digitized by Google

of the cell, is for breaking the main charging circuit, the diagram showing the conditions during charge. After the circuit has been opened the switch U is turned and this disconnects the bat-

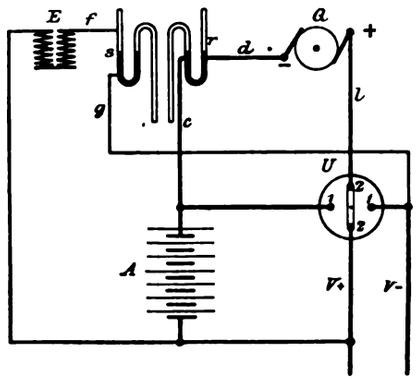

FIG. 5.—A SWITCH WORKED AUTOMATICALLY BY THE "GASSING" OF STORAGE BATTERIES TO CUT OFF THE CHARGING CURRENT.

tery and the charging circuit. The left hand tube is for operating the electromagnet E, which is connected only to the discharging circuit as shown, and operates a valve which releases the air pressure in the accumulator when the armature is drawn up; when the switch U is turned for discharging, a momentary current will flow through that electromagnet and this opens the air valve and allows the mercury in both tubes to assume its original position. In order to prevent the columns of mercury from moving up and down with a pendulum action, the bottom of the mercury tube is made extremely small, so as to allow the mercury to flow through only slowly. An alarm bell to indicate when the batteries are charged could very easily be added.

---

**An Odd Inductor Dynamo.**—Foreign papers have recently published many notes from correspondents at the electrical exhibition at Como, Italy. Among these notes many interesting types of machines are described. One unusual machine is that shown in Fig. 6, which is reproduced from the London "Electrical Review." The peculiarity of the machine is the fact that the field and armature coils are wound on the same poles, the rotor serving merely to vary the mutual induction between the two circuits. Although one of the first inductor dynamos ever proposed was designed on these lines, such a machine has never been reduced to practice in this country. It will be noted from the figure that the coils are all pole-wound upon the internally projecting poles of the external stationary ring. There are three times as many of these poles as there are rotor poles facing them. Each armature coil is closely sandwiched between two field coils on each pole, this arrangement reducing magnetic leakage. The field coils are so connected as to make alternate poles north and south, and the rotor as it draws away from one stationary pole approaches the second one from it, so that the average reluctance of the magnetic circuit through all of the field coils is not varied and the movement of the rotor therefore causes no alternating back e.m.f. to be impressed upon the field circuit. There are three times as many stationary poles as there are moving poles and the coils of one phase are mounted upon every third pole. It will be noticed that all the poles of one phase are at one instant covered by the iron of the rotor and at another instant uncovered and confronted only by a wide expanse of air. This causes the flux in any individual pole to vary up and down as its magnetic circuit is closed and opened, setting up alternating currents. There being three times as many poles on the stator as there are on the rotor the coils give currents displaced one-third of a cycle from each other, i. e., they give three-phase currents.

---

**The Connections of Subcribers' Instruments on Common Battery Exchanges.**—It frequently happens that American electrical publications are obliged to obtain information on American subjects

FIG. 6.—AN INDUCTOR DYNAMO WITH THE ARMATURE AND FIELD COILS WOUND ON THE SAME TEETH.

from foreign sources, owing to the reluctance of those in authority on this side to give out the same information. Such a case is that of the common battery telephone system used by the American Bell Companies and constructed by the Western Electric Company. In an article which recently appeared in the London "Electrician" many of the details of this system were given out, one of the most interesting features hitherto unpublished being a special method of connecting the subscribers' instruments, wherein an induction coil is used for purposes mentioned below.

Translating the English diagram into American conventional forms, the instrument is shown in Fig. 7. From this diagram it may be seen that when the receiver is on the hook switch the only path from line to line through the instrument is via the magneto bell in series with a condenser. This allows the ringing currents to actuate the bell, but holds the line open against the battery electromotive force constantly applied from the telephone exchange. When, however, the telephone receiver is removed from the switch a metallic connection is made across the line through one side of the induction coil and the microphone. This allows the passage of direct current from a common battery, which operates a relay attached to that line at the central exchange, this relay illuminating the proper visual line signal in front of the answering operator at the switchboard.

The hook switch also closes another circuit through the two sides of the induction coil in series with each other and in series with the receiver, this whole circuit being in parallel with the magneto bell and in series with the condenser across the line conductors. Direct current does not pass through this line, as the condenser is contained within it, but alternating voice currents do. The primary of the induction coil, i. e., the winding connected in series with the transmitter, has a resistance of 15 ohms, while the secondary, i. e., the winding in series with the receiver, has a resistance of 30 ohms. As voice currents from the distant end of the line must necessarily, in order to reach the receiver, pass through these two coils in series with each other, they are necessarily wound and connected in opposite directions, i. e., a current which circulates in one right-handedly circulates in the other left-handedly, so that they in part neutralize each other's effect upon the core, and hence do not act as an inductive coil to choke alternating currents passing through them in series, except in so far as one has a greater number of turns than the other. It will be noticed that apparently the path from one line through the 15-ohm coil and the transmitter to the other line would tend to short-circuit the receiving instrument and reduce the effect upon it of voice currents from distant stations, but this is compensated for by the transformer action of the induction coil, which, when alternating cur-

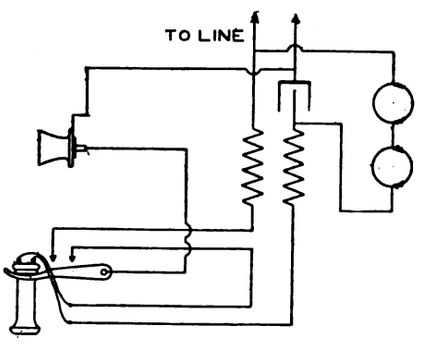

FIG. 7.—THE USE OF AN INDUCTION COIL ON A COMMON BATTERY SYSTEM.

rents pass through its 15-ohm side sets up similar currents in the 30-ohm coil in series with the receiver and condenser. It is noticeable, however, that these currents in the 30-ohm coil necessarily have to pass through the 15-ohm coil; thus the

Digitized by Google

induction coil connected in this manner serves as a choke coil to prevent alternating currents from short-circuiting around the receiver through the transmitter, and also serves to allow direct currents to pass from the line through its primary and the microphone without

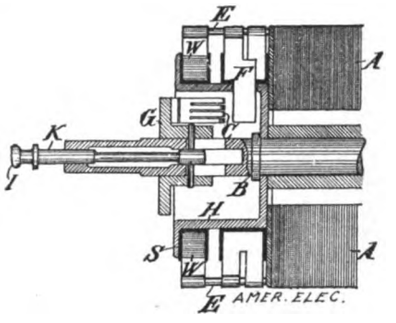

FIG. 8.—AN ARRANGEMENT FOR SHORT CIRCUITING ROTATING RESISTANCES IN AN INDUCTION MOTOR.

passing through the comparatively high resistance receiver, a very desirable object. The system of connections is a most ingenious one and is the outcome of several less perfect ones drawn up by engineers of the American Bell Company. The article above referred to gives other details, some of which have appeared in American publications through patents issued to their inventors.

**A Starting Device for Induction Motors.**—For maximum efficiency the polyphase induction motor must be made with a secondary circuit of as low a resistance as possible, the secondary usually being a squirrel cage of copper rods riveted to copper rings. This arrangement is, however, badly adapted for starting since, when the magnetic field is rotating at a speed much higher than that of the rotor, as it is when the latter is at or near standstill, the electromotive forces in the short circuited secondary are correspondingly higher, due to the increased rate of cutting lines of force, and excessive currents are set up. These not only require an excessive current from the line, but by their distorting action on the field tend to cause serious magnetic leakage between the primary and secondary and thereby not only greatly reduce the torque per ampere, but even reduce the total torque in spite of the excessive number of amperes. The simplest means of overcoming this difficulty is to insert in the secondary circuits, while starting, a group of non-inductive resistances, which will check this excessive flow of currents and with which the torque per ampere can be made as high at low speeds as at full speed, although of course at a reduced efficiency, due to the reduced output of power at the low speed. One means of accomplishing this is to wind the secondary with coils connected to collector rings from which the currents can be led out to resistances or short circuited. This, however, does not allow the use of a cheap and durable low voltage bar winding or squirrel cage, as the collector ring resistance would prove too high for the large currents generated by it. In a series of notes on electrical features of Switzerland appearing in the "London Electrician" for the benefit of the excursionists of the Institution of Electrical Engineers who recently visited Switzerland, the Alioth starting device was described. It consists of a set of resistances inserted in the secondary windings and rotating upon the shaft of the machine with a special rotating switch for short circuiting them when the machine approaches full speed. The arrangement of the parts is shown in the accompanying diagram, Fig. 8, in which A represents the laminated core of the rotor of the motor and E and E represent bars of the winding. These bars are cross connected with spiral end connections in the usual way just to the left of the end plate of the core, but a few of them (3 per pair of poles) extend further out to the left and are connected to resistance straps, W. The bars also carry knife contacts, F, which may be closed upon the jaws, C, mounted on the disc, G. This disc is mov-

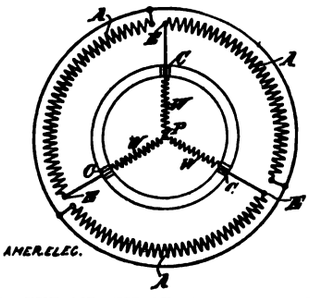

FIG. 9.—THE CIRCUIT OF THE SECONDARY OF THE MOTOR SHOWING RESISTANCES AND SHORT CIRCUITING RING.

able axially by means of the central spindle, K, through the hollow shaft and attached to the handle, I. When this handle is pushed in the jaws make contact with the strips, F, and thereby short circuit the resistances, W. A diagram of the circuits is shown in Fig. 9, in which A A A are the secondary windings Y-connected to the external circle. The windings evidently generate currents through the Y-connected resistances, W W W, to the common central point, P, except when the resistances are short circuited by the ring, C C C. A similar arrangement is used by the General Electric Company of this country, the main difference being that in its device the movable contacts sweep over a number of segments, cutting out the resistance gradually instead of in one step.

**A Combined Hydrocarbon and Electric Motor Automobile.**—The advantages of the easy starting and overload capacity of the electric motor and the continuous operation of the gas engine have been combined in a line of automobiles in this country, a description of which appeared in the July issue of the American Electrician, and also in a vehicle called the Petro-Accummobile, manufactured by Les Etablissements Pieper, a description of which recently appeared in "l'Industrie Electrique." A general view of the running gear with the body removed is shown in Fig. 10. The gas engine is in this case of the vertical, single-cylinder trunk piston type and is mounted forward on the vehicle over the forward axle, extending up under a hood which constitutes the dash board. It drives through a horizontal shaft a dynamo mounted centrally under the vehicle, and the shaft extends through to the rear of the dynamo and enters a changeable gear, the casing of which appears at a slightly lower elevation than that of the electrical machine. This gear in turn drives through a bevel and differential gear at the rear, connected to the axles of the driving wheels. The gas engine runs constantly at approximately uniform speed and output whether the vehicle is moving rapidly or slowly or standing still, the control of the speed being accomplished solely through the changeable gear. The excitation of the dynamo can be changed slightly to vary the speed on any one gear. The only time it is necessary to stop the gas engine is when it is desired to reverse the direction of the vehicle. This is accomplished by running the dynamo backwards as a motor. In regular running, the dynamo acts either as a generator or a motor according to whether the output of the engine is greater or less than the power used by the vehicle. The total weight of the latter, which is a trap with one seat for two passengers and a rear seat for a groom, is, without passengers, about 1300 lbs. The output of the gas engine is the equivalent of 2500 watts and the capacity

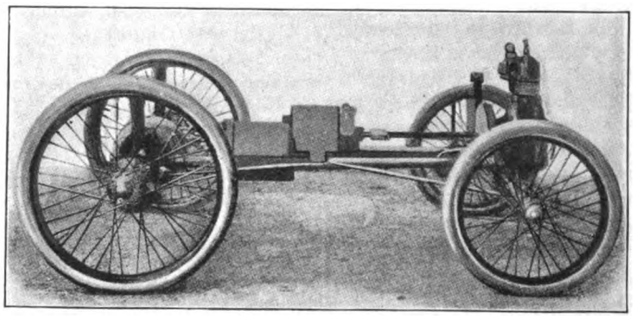

FIG. 10.—THE RUNNING GEAR OF A FRENCH AUTOMOBILE WITH A GASOLINE ENGINE AND DYNAMO AND STORAGE BATTERY.

Digitized by Google

of the dynamo and of the storage battery is in the neighborhood of 1800 watts. The battery weighs only about 270 lbs. all told and is capable of discharging at the high rate of about 9 watts per pound of total weight, this high rate of discharge being due to the fact that it is always charged up to a high pressure and constantly receiving and taking charges for a short time duration, never being called upon for a long continued discharge.

# Some Recent Electrical Patents.

**An Electrolytic Lamp.**—Electrical engineers in this country have not been idle in the development of electric lamps on the general lines of the Nernst lamp. A patent recently issued to W. E. Irish describes a modification of the ordinary arc lamp by means of which a rod or tube of some material which, when heated, conducts the current and emits light at a high efficiency, is substituted for the arc between two carbons, the arc serving as a means of heating this material and thereby starting the lamp. One proposed arrangement is shown in the vertical section reproduced in Fig. 1, in which 1 and 1 are the carbons between which an arc is sprung, which heats up the sleeve of a normally non-conducting oxide of a rare earth until it conducts the current from one carbon to the other, when the arc may be extinguished, the lamp becoming electrolytic in character. Patent No. 626,787.

**An Electrostatic Measuring Instrument in Vacuo.**—For the measurement of very high voltages or the detection of grounds upon high voltage lines, electrostatic voltmeters are far preferable to electromagnetic instruments owing to the enormous resistance that must be used with the latter as well as to the considerable loss of power required to give sufficient current to operate the instruments. Electrostatic instruments get into difficulties, however, at these pressures owing to the sparking distance and the necessity of separating the fixed and movable element of the measuring instrument a considerable distance apart, which greatly reduces the inherently weak force of electrostatic attraction and repulsion. Prof. Elihu Thomson has patented a means of overcoming this difficulty by enclosing the instrument in a glass tube or bulb, exhausted to an extremely high Crookes vacuum so great that the sparking distance of a given voltage is greatly reduced and the vanes and quadrants can be brought with safety much closer to each other than they could in open air, thereby increasing the electrostatic forces which give the measuring deflection and reducing greatly the delicacy of the instrument. A suggested arrangement is shown in plan in the cut, Fig. 2, wherein F is a base, B is a Crookes tube containing the vanes, $S^2$, working between the quadrants, $S^3$, connected with the terminals, T and T'. The vanes are restored to the zero position by the spiral spring shown and indicate by means of the pointer, C, working over the scale shown in the lower part of the figure. The claims upon this improvement are extremely broad, covering generally the enclosure of a measuring instrument in a vacuum. Patent No. 627,155.

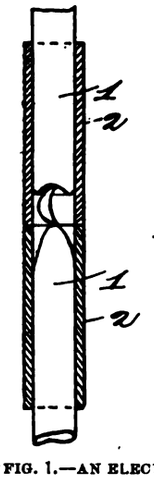

FIG. 1.—AN ELECTROLYTIC LAMP.

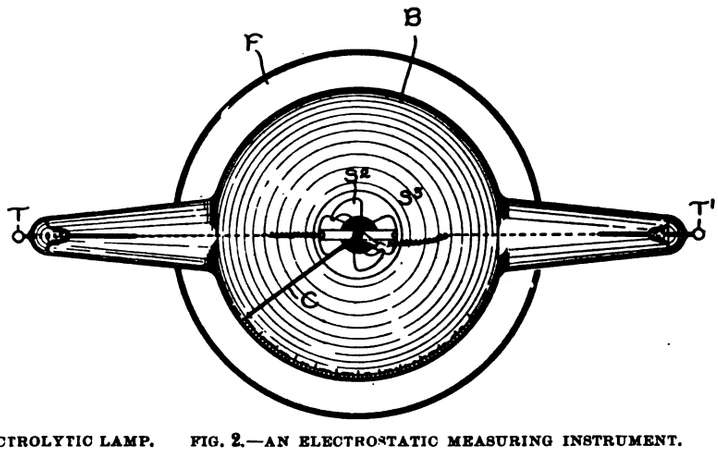

FIG. 2.—AN ELECTROSTATIC MEASURING INSTRUMENT.

**A Relay Switch for Sectional Conductor Railways.**—There have been many plans proposed and patented for the operation of the switches of sectional conductor or button-contact railways by means of magnets carried by the cars and projecting their fields of magnetic force down through the road bed to magnetically operated switches buried therein. One difficulty with such systems is the transmission of sufficient magnetic intensity through the necessarily wide air gap to operate switches of the size and weight required for making and breaking street railway circuits. A recent patent issued to Mr. Robert Lundell describes and claims the use of a relay buried in the ground and affected by the magnetism sent into it from the car above, this relay having moving parts of light weight which close the circuit of a main switch which may be located near by or grouped with other switches in what is known as the vault system. In Fig. 3, which is a diagrammatic cross-section of the track, R and $R^1$ are the service rails, B is the third rail or button contact on which slides the shoe or skate $S^1$ attached to the car, and N and S are long parallel rods of iron or steel magnetized by the magnet M, which is supplied, as shown, with current from the storage battery $B^4$. These send downward into the roadbed the field of force represented by the dotted lines, which affects the small relay D, one for each section of the track. The moving parts of this relay are connected in circuit between an auxiliary feeder of low voltage, $F^1$, and the coils of the main electro-magnetic switch, $M^1$, so that when the relay is affected by the magnetism sent to it by the car it closes the circuit, which energizes the main switch, which in turn connects the sectional conductor with the main feeder, F. Patent No. 625,512.

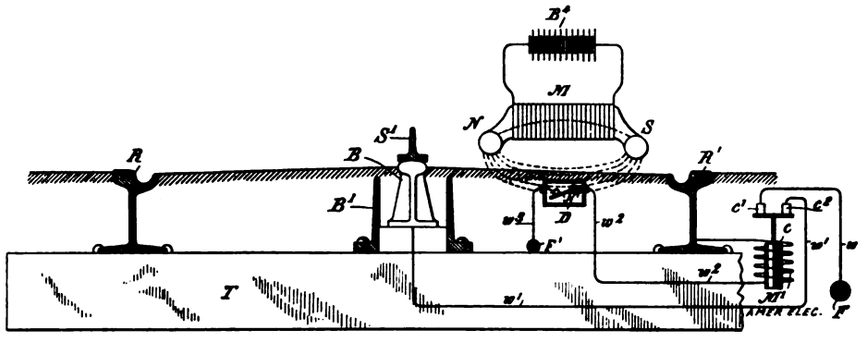

FIG. 3.—A RELAY SWITCH FOR SECTIONAL CONDUCTOR RAILWAYS.

**A Pneumatic Multiple-Unit System.**—The operation of the various controllers of the several cars of a train composed of motor cars, all from one platform, in such a way that the motors shall all work together, requires apparatus of considerable complexity, which has in the few designs hitherto proposed been entirely electrical. Mr. Geo. Westinghouse describes a complete arrangement for this purpose in a patent containing 12 sheets of drawings and 43 claims, in which apparatus the pneumatic pressure of the air brake system is made use of to operate the controllers, the valves being actuated by

Digitized by Google

magnets, the whole arrangement of brakes and controllers being closely interacting, so that, among other things, the application of the brakes serves to cut off all current from the motors. Patent No. 624,777.

**An Automatic Grounding Device for Secondary Circuits.**—To maintain insulation between secondary alternating cir-

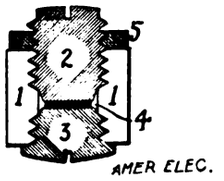

FIG. 4.—AN AUTOMATIC GROUNDING DEVICE FOR SECONDARY CIRCUITS.

cuits and ground, except when they become crossed with the primary under such conditions as to establish a high and dangerous voltage between the secondary and ground, Messrs. E. J. Houston and A. E. Kennelly have patented a new form of insulating gap such that the high tension will break down its dielectric strength, the general purpose of which is the same as that of the Cardew earthing device or the Thomson film cutout. The new device consists of a small button or layer of a chemical substance which allows but a trifling leakage of current at low voltage, but when subjected to high pressure undergoes a chemical change which reduces its resistance. Among the commercial substances which they suggest are: Manganese dioxid, stannous chlorid, lead acetate, copper bichlorid, copper and ammonium chlorid, and silver sulfid. The accompanying drawing shows one arrangement of such a device, consisting of an insulating sleeve, 1, tapped to receive the metal plugs, 2 and 3, between which is the chemical substance, 4. One of the metal plugs is then connected to the circuit to be protected and the other to the ground. Patent No. 625,395.

**A Glycerine Switch for Railway Controllers.**—To take the arc which always exists in breaking the circuits of railway motors, Mr. H. A. Wurts, the designer of the well known Wurts lightning arrester, has patented a special form of switch to be used in combination with the Westinghouse controller, as shown in the broken elevation, which is reproduced in Fig. 5. The switch is located below the controller proper at a point represented by 12 in chamber 8, which is filled with some liquid, preferably glycerine for reasons given below. The switch is actuated by means of a peculiar friction clutch upon the controller spindle proper. This clutch is so designed as to open the switch when the controller passes from the series to the multiple position and also when the controller is turned from any running notch toward the off position, so that the current is not passed through the controller contacts as they travel under the fingers while the power is being shut off. Mr. Wurts states that as a result of his experiments he found that any non-conducting liquid, if closely confined so that the arc has no chance to vaporize it and provide itself with a gaseous path through the liquid, is suitable for use on such a controller. For this reason the chamber is made with no outlet except a small pin hole, shown at 15, and put in so that the liquid shall not burst the strong walls in case of expansion. The liquid should be one which is not easily carbonized and which is non-combustible, and preferably having a slight conductivity so that the induced electromotive force of self induction on breaking the circuit shall have a path for its discharge. The liquid should also be unchanged by the extreme variations of temperature to which a railway motor is likely to be subjected. Glycerine has been found to best meet these requirements. The claims are

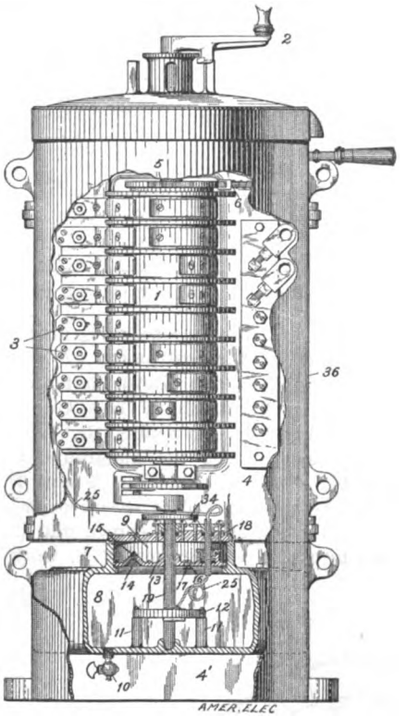

FIG. 5.—A GLYCERINE SWITCH FOR RAILWAY CONTROLLERS.

very broad, the first reading: "The combination in an electric controller of a switch and an auxiliary switch in circuit therewith having its contact portions immersed in an arc extinguishing preparation." Patent No. 625,232.

**An Incandescent Lamp Filament of Highly Refractory Material.**—Mr. T. A. Edison, in his characteristic way of taking up and developing the different branches of electrical engineering in which others have started notable improvements, has recently filed an application on a lamp using a filament of a highly refractory non-conducting substance, evidently inspired by the promising future of the Nernst, Maxim and other lamps of recent invention. In an equally characteristic way he describes and claims broadly a form of construction which is, in the present state of the art, apparently quite impracticable, but which may establish his claims to valuable processes should this branch of electrical engineering develop to a high state of perfection later. The invention consists of a filament of a highly refractory non-conducting material, preferably porous, incorporated in which are isolated particles of carbon, such as to produce spark gaps within the filament, across which gaps high-tension currents may be discharged and by their sparking be made to heat the filament to incandescence. The materials mentioned are the oxids of the rare earths, zirconium, thorium, etc., in which the isolated particles of carbon may be incorporated by the carbonization of an organic compound mixed with the oxid or the carbonization of the tartrate of the oxid itself. The patent also describes the dipping of the filaments in a salt of the oxid, such as the acetate, to provide an exterior surface of high emissivity. The first claim of the patent is extremely broad and reads as follows: "An improved filament for incandescent lamps, consisting of a highly refractory non-conducting material, having isolated particles of conductive material therein, substantially as set forth." Patent No. 626,460.

**An Improved Binding Post.**—One of the most troublesome features of electric bell, signal, telephone and telegraph systems is the binding post, which is so likely to work loose in time and give a poor connection. For this reason it is common in high-grade telephone work to solder a great many joints at the expense of considerable inconvenience in changing the circuits. An improved form of binding post in which a lock nut performs a double function is shown in two views in Fig. 6, and is patented by Mr. J. F. Gilliland. It is of the upright form, tapped at c for fastening upon the usual machine screw, with projections b b for holding it from twisting on the base upon which it is mounted. It is drilled with the usual lateral hole, C, to receive the wire to be fastened into it which is bound by the screw B, which, in turn, is fastened by the lock-nut D. The main post is split, as shown at a, and terminates in

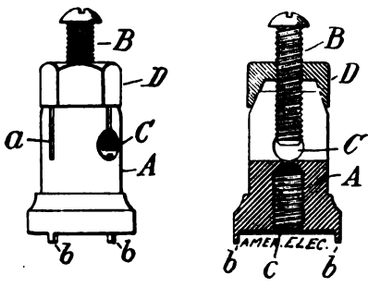

FIG. 6.—AN IMPROVED BINDING POST.

a conical end which is enclosed by the countersunk section of the lock-nut. The latter, therefore, acts as an ordinary lock-nut and also serves to jam the four sections of the post around the screw. The spring of these sections, combined with the wedging action of the tapered nut, gives a fastening which is not liable to work loose. Patent No. 625,668.

# NOTES.

**The Annual Meeting of the Association of Edison Illuminating Companies** was held in Philadelphia, September 12th to 14th, inclusive. Papers were read on automobiles, meters, motors, lamp testing, station accounts, station practice and statistics.

**The Great Falls Power Company** is preparing plans and specifications for a water power plant at the great falls of the Potomac. The plant will contain sixteen 2000 h. p. units. The power will be used for the consolidated electric light and street railway system of the Washington Traction & Electric Company, an account of which was given in a recent issue of the American Electrician.

**The Brooklyn Institute of Arts and Sciences** has issued its prospectus for 1899-1900. In the department of electricity there are announced several interesting lectures, one of them on "Some of the More Recent Problems of Electric Lighting," by Mr. W. S. Barstow, Supt. of the Brooklyn Edison Company, and another on "The Regulation of Electric Apparatus on Electric Railways," by Mr. Frank J. Sprague.

**An Automobile Meet at Newport.**—The present rage for automobiles among the wealthier classes is well illustrated by an automobile parade which was held September 7th at Newport. Nineteen automobiles were in line, a number of which were driven by their owners, prominent in financial and social circles, who took part in a driving contest over a course obstructed with many grotesque imitations of probable obstructions, such as dummy nurse girls, baby carriages, wooden policemen, etc. The parade and contest were organized and carried through by Mrs. O. H. P. Belmont.

**The Commemoration of Volta.**—In spite of the recent destruction by fire of the buildings of the exposition at Como, Italy, the proposed ceremonies to commemorate the centenary of the discovery of the Voltaic pile were held at Como, September 18th to 23d. Very remarkable energy has been exhibited in the rebuilding of the structures burned and the re-establishment of the exhibition with new exhibits. The ceremonies were in part a National Congress of Electricians, instituted by two Italian societies, one the Italian Electrotechnical Association and the other the Italian Society of Physics.

**An Electrically Operated Mail Dispatch Tube in London.**—Some 35 years ago there was built from the general Post Office in London, England, to one railway station and one branch office an underground tube for the rapid dispatch of mail. The tube was operated for a few years by means of compressed air and finally abandoned. It is now proposed to re-equip this tunnel with electrically driven apparatus. The tube is made up of cast iron segments, the bore being about 4 ft. high by 4 ft. 6 in. wide. It is proposed to equip it with electric locomotives each capable of pulling six or seven trailers carrying about one ton of mail matter each.

**The National Export Exposition.**—On Sept. 14th the official opening of the National Export Exposition took place with appropriate ceremonies in Philadelphia. The exposition will remain open until Nov. 30, its purpose being to encourage export business between this and foreign countries, and particularly Southern and Central American states. The exhibits are of appropriate interest to representatives and visitors who are expected to attend from these lands. The electric exhibits are to a large extent of small apparatus of general application rather than large or special machinery. The exhibition is, of course, largely illuminated electrically, and different sections of the buildings and grounds are illuminated in different ways so that a comparison can be had of the effects obtained by incandescent gas, incandescent electric light and arc light methods.

**Decorative Lighting in Philadelphia.**—What has come to be known as the Avenue of Fame, on Broad Street, north and south of the City Hall, Philadelphia, was again illuminated this year in connection with the G. A. R. encampment after the same general style as last year's Peace Jubilee illuminations. Some 62 columns of staff stood 50 feet apart from Cherry Street on the north to Walnut Street on the south, the corner columns being 55 feet and the intermediate ones 45 feet in height. A line of bunting and laurel was swung between the columns, and below this decoration was a festoon of thirty-four 16-c. p. lamps. Each column at the street corners was lighted by 154 and each intermediate column by thirty-four 16-c.p. lamps, judiciously arranged to bring out the architectural features and throw a strong light on the bunting and flags. The current for the lamps was supplied by the Edison Company and the 6,000 lamps and wiring were installed by the Sawyer Electrical Company.

**A Special Train to the Street Railway Convention.**—The committee on transportation of the American Street Railway Association has arranged for a special train from the East to Chicago for the convention opening October 17th. The train will run on the following schedule:

Leave Boston 10:30 A. M. Sunday, October 15.

Leave New York 1 P. M. Sunday, October 15.

Leave Albany 4:35 P. M. Sunday, October 15.

Leave Buffalo 12 midnight Sunday, October 15.

Arrive Chicago 2:30 P. M. Monday, October 16.

The train will consist of Wagner vestibuled drawing-room sleeping cars and dining cars serving meals through to Chicago. A special rate of one and one-third fare on the certificate plan has been made, and delegates when purchasing tickets should ask ticket agent for certificate, which, on presentation at Chicago, will secure one-third fare for the return trip.

**The Department of Electrical Engineering** of the University of Illinois announces that there has been added a number of courses of study in the fields of electro-metallurgy, alternating-current working and polyphase testing, and electric lighting and power plants. The equipment of the electrical engineering laboratory is being continually increased for regular and advanced work in these branches. The four years' undergraduate course has been made elective for the last year and a half; that is, a student may elect his further work in: (1) regular electrical course; (2) electro-physical course; (3) electro-chemical course. The degree of electrical engineer is given only after completion of five years of work. The fifth year is devoted entirely to special work. The principal or primary subjects are elected from the advanced electrical engineering course; the secondary or subordinate subjects are elected from the advanced courses in mathematics, physics, chemistry and mechanical engineering. The department is in charge of Wm. S. Aldrich, Professor of Electrical Engineering.

**The Tests of Street Railway Brakes in New York City.**—On August 29th and 30th and September 7th the railroad commissioners of the state of New York began the tests of a large number of electric, air and mechanical braking devices for street cars. These tests were carried out on a line of the Metropolitan Street Railway Company's system in New York City, each maker of the device fitting it to one of the company's double truck cars. Fourteen speed and distance curves were taken of each brake submitted under emergency stop, three each at 8, 12, 15 and 16 miles per hour and two at the last speed, using sand. An ingenious automatic recording device was arranged in such a way that it could be shifted from car to car under test. It consisted of a Boyer speed recorder fitted with an electrical contact which, when the speed rose to the proper value, notified the motorman to set the brake and automatically started the time and distance recording apparatus. The latter consisted of a pencil driven by clock work in one direction over paper driven by the motion of the car in a direction at right angles to that of the pencil.

**The Study of Electrical Engineering at Drexel Institute.**—The course of instruction in electrical engineering at the Drexel Institute of Art, Science and Industry in Philadelphia is planned to, so far as possible, bring out the intimate relation be-

Digitized by Google

tween the theoretical and practical sides of engineering, so that while the former is not neglected it is not necessary for the graduate to spend years getting practical experience and harmonizing his theoretical ideas with practical conditions. The electrical engineering course requires two years, the admission requiring either a previous study of the two years' course in Mechanic Arts or the passing of examinations on the subjects there taught. New additions have been made recently to the equipment of the laboratories, notably in the line of three-phase apparatus, in which motors and a rotary converter have been added, of sizes large enough to illustrate real engineering practice. In addition to the day courses are evening classes in applied electricity, organized along two lines, one a simple course requiring one year's time for the machinist, artisan or salesman who wishes to increase his familiarity with electrical matters, the other a more thorough course requiring two years' time. The work of both day and evening classes is in charge of Prof. Arthur J. Rowland.

**An Electrically Wrecked Bridge.**—A novel application of electric heating was the wrecking of three spans of an old wooden bridge at Clinton, Indiana. It was desired to use the masonry piers for a new structure and the old bridge could not be wrecked by dynamite or burned without injuring them; neither could it be taken down without erecting falsework or loosened by hand and allowed to drop without great risk to those doing the work. Twenty-seven timbers, each 8 ins. square, composing the chords of each span, were simultaneously cut through a short distance from the piers by loops of No. 12 iron wire heated red hot by electric currents. The loops were weighted so that as they burned the timbers they were forced more deeply into them. Each span was brought down separately and the 54 loops of wire to each span were connected in three circuits of about 13 loops in series, these three series groups being connected in parallel across a 52-volt secondary a. c. circuit. The time required to burn through the wood until the weight of the spans carried them down averaged about one hour and a half. The current consumed varied from about 400 amperes during the first minute to 200 amperes after one hour's application, the heat from the burning wood raising the temperature of the wire and with it the resistance. The method was proposed by Mr. H. N. Mills of Clinton and proved entirely successful.

---

**A Large Hydraulic and Electrical Plant in Brazil.**—Owing to the cost of fuel in many parts of South America the development of conveniently located water power promises to be most profitable. The population of many South American centers is also much greater than most people unacquainted with that continent imagine, so that the demand for power is by no means insignificant. One of the largest proposed plants is that of the Sao Paulo Railway, Lighting & Power Company, Ltd., which has been incorporated with a capital of $5,000,000, financed by the Ross, McKenzie Syndicate of Montreal and Toronto, Canada, and engineered by Mr. F. S. Pearson, the well known chief engineer of the Metropolitan Street Railway Company of New York City, and leader in electrical conduit traction work. The city of Sao Paulo has a population of 280,000 inhabitants. The plant will be located on the Tiete River, twenty-four miles above the city, where there is a flow of 150,000 cu. ft. per minute, which, with a granite dam 1000 ft. long and 35 ft. high, can be backed up to a sufficient height to give about 16,000 h. p. The flow will be carried in two of the largest pressure conduits in existence, each 3000 ft. long, with a diameter of 12 ft. The hydraulic work will cost the company in the neighborhood of $1,500,000. A contract has been signed with the Stilwell-Bierce & Smith-Vaile Company, Dayton, Ohio, for the turbines and other hydraulic auxiliary apparatus. This order calls for the supply of four special Victor turbines of 2000 h. p. each. The equipment is built to furnish the power for 100 miles of trolley lines and for many large factories. The New York office of the company desires to send to Brazil a complete line of catalogues pertaining to electrical and mechanical industries in order that the company may encourage installations for the use of its power and be posted on American apparatus suitable for such work.

---

**Skin Effect in Aluminum Wires.**—Owing to the fact that the increased resistance of conductors of alternating currents, due to what is called the skin effect, increases with the diameter, fears have been entertained by some engineers that this effect would seriously reduce the efficiency of long-distance transmission lines using the great cross sections of aluminum necessary for carrying considerable amounts of current, especially on such lines as use a frequency as high as 60 cycles. The effect is, however, exactly the same as in copper lines of equivalent cross section. This is due to the fact that the skin effect expressed as a ratio of the ohmic resistance under alternating currents to that of the same conductor with direct currents depends both upon the specific resistance of the material and upon the diameter of the wire or cable. An increase in diameter causes an increase in the skin effect, which is in reality an unequal distribution of the current, by which there is a greater density of current at the surface of the wire. If, however, the specific resistance of the conductor is greater, this greater resistance tends to prevent the unequal distribution of the current. The two elements vary in such a way that if the diameter of the material having a greater specific resistance be made sufficiently large to give the same resistance in a given length to the flow of a direct current, then the tendency to skin effect, due to increased diameter, is just counterbalanced by the increased specific resistance. The skin effect, therefore, in a copper wire is just the same as it is in an aluminum wire, if the diameter of the aluminum wire is increased so that it has the same ohmic resistance as the copper wire. This relation can be seen immediately from the formula for skin effect, as the terms representing specific resistance and diameter of wire are so related that when material of a different specific resistance is used the consequent change in diameter in order to maintain the same resistance in the conductor causes no change in the value of the fraction representing skin effect.

---

**The Distribution of Power to Trunk Electric Railways by Means of Gas.**—The following very significant extract from a signed statement of Mr. George Westinghouse presents a novel means of operating existing steam railways by means of electric traction, which because of its radical departure from existing practice would meet with no little skepticism but for the undoubted authority of the writer.

"Long familiarity with the electrical industry, the pipe-line transportation of natural gas in great quantities, and, during the past seven years, an active interest in the development of large gas engines, satisfy me that the economies which will result from the distribution of power by means of gas generated at central points, and conveyed in suitable pipes along the lines of railway for the operation of engines and electric generators, will be sufficient to justify the expenditure of the capital necessary for the electrical operation of railways, particularly of metropolitan and suburban lines."

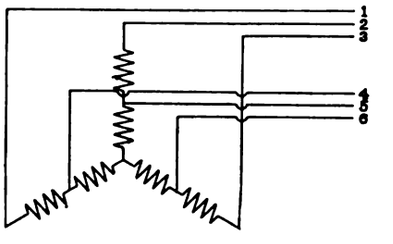
Some idea of the arrangements which would be adopted on lines equipped in this way can be gained from the following extract from the same source, although not over the same signature:

"The great demand for large electric power units will undoubtedly be in connection with the operation of suburban and interurban railways and tramways. A careful inspection of the very latest electric plans would disclose the following general outline: A large, central steam power and electric generating plant, the electric generators being of the multiphase type for the generation of currents at very high voltages; a high tension system of distribution to take these currents to local stations, where there are step-down transformers which supply alternating currents to rotary transformers, which, in turn, feed direct currents to third rail or other circuits, for the operation of the motors on the railways.

"There seems to be no doubt that coal can be made into gas of a satisfactory quality at gas works suitably located, and can be taken by pipes to gas engines placed in the positions corresponding to the sites of the rotary transformers of the foregoing plan, for a capital expen-

Digitized by Google

diture greatly below that required for an equivalent steam boiler and engine plant. The cost for fuel per electrical horse power so delivered should not exceed 50 per cent. of the cost of the fuel for generating electricity by steam for similar service."



**A Proposed Municipal Transmission Plant for Lighting Chicago.**—The Chicago drainage canal has at some points a series of falls which will make available a considerable amount of power. It has been proposed that the city should utilize this power for lighting the streets.

At a recent conference of engineers to discuss the subject, Mr. F. B. Badt of the Meysenberg & Badt Company, assuming a line of pressure of 40,000 volts, estimated the cost of installation, less the pole line, permanent works and right of way, as $45 per horse power, delivered at the sub-station—the city terminal of the pole line. The approximate cost of the pole line he put at $9 per horse power, which would bring the cost of the hydraulic and electrical installation up to $54 a horse power. Assuming that the initial horse power to be transmitted was 20,000, he estimated the cost of the installation, exclusive of the dam, tail race and water wheel pits, at $1,080,000. Then, allowing $400,000 for the cost of the distributing plant in the city, and adding $20,000 for incidentals, he estimated the cost of the plant would be about $1,500,000.

He placed the operating expenses, interest on the investment and depreciation of plant at $12.25 per horse power per year. On the assumption that the lessee of the water power would pay the district an annual rent of $10 a horse power, he showed it would cost him $14 a horse power to deliver it to his customer; adding $12.25 to this figure, Mr. Badt estimated that the cost of a horse power a year would be about $26.25 at the point of consumption.

City Electrician Ellicott said that Chicago to-day is lighting 3,000 arc lights from three electrical plants; that it would take 16,000 lights to light the built up parts of the city, requiring about 14,000 horse power. The cost per horse power per year to the city for electric lighting by a steam plant is $34.37, exclusive of interest on the investment and depreciation of machinery. He estimated that the city by building a modern steam power plant to light 16,000 arc lamps could get its horse power for $27 per year. To this he added $8 a horse power per year for interest and depreciation, bringing the cost up to $35, on a working basis of ten hours and thirty-seven minutes each day. He estimated that if the city were to install a hydraulic and electrical plant to light 16,000 arc lights, the expenditure would amount to $1,980,000; adding to this the estimated cost of $1,200,000 for constructing a dam, tail race, etc., would bring the aggregate cost of the whole plant up to $3,180,000. On this basis, he said, the city could afford to pay the sanitary district $9 a horse power per year at the water wheel to bring the cost per horse power of the hydraulic-electrical system up to the cost of the steam electrical system.

**A Simple Two-Phase System of Secondary Mains.**—On the distributing network of the Hartford Electric Light Company, a description of whose plant appeared in the July issue of the American Electrician, there is in use a simple means of distributing with a minimum number of wires the two-phase currents for both lights and motors. The secondary mains are three-wire for lighting and two-phase for power, largely underground and supplied in districts by manhole transformers. Each manhole has two transformers, one for each phase; each transformer being tapped out at its central point for the neutral of the three-wire 220-volt network. The secondaries of the two transformers are shown at A and B in the accompanying diagram of connections. One outside terminal of A is connected to one outside terminal of B, and in each direction four wires are carried. It will be noticed that to the right the upper three wires are those of the three-wire single-phase circuit from transformer A, and the lower wire coming from transformer, B, with the wire next above it gives a pressure of 220 volts of the other phase to motors in that direction. The neutral of transformer A is not carried to the left, while that of transformer B is, and all lights in this direction are supplied from the three-wire system of the latter transformer, while in this direction also one wire serves commonly as one outer of the three-wire system and as one side of the secondary of the other phase. Thus four wires serve to give a three-wire lighting and a two-phase motor distribution and the lights are approximately equally divided between the two phases. The neutrals are, of course, not connected in to the motors, which run at 220 volts on each phase and are wired on the two-phase three-wire principle. It is obvious that there is between the upper and the lower wires going out in each direction an electromotive force consisting of the vectorial resultant of the two 220 volts which amounts to about 310 volts, but this increased pressure is no particular disadvantage on low-tension circuits. It is also obvious that the wire used commonly by both phases gets an increased current but not sufficiently so to materially affect the regulation. The system has proven perfectly satisfactory.

THE CONNECTIONS OF SECONDARY NETWORKS FOR THE DISTRIBUTION OF TWO-PHASE POWER AND THREE-WIRE LIGHTING ON FOUR WIRES.

**Marconi in This Country.**—Through the efforts of some of the leading daily papers Signor Guglielmo Marconi, with several assistants, is now in this country to take charge of the reporting of the international yacht races by means of wireless telegraphy. The transmitter apparatus has been installed in the pilot house of an ocean-going steamer, the Ponce, there being two receiving stations, one on the Navesink Highlands and the other on the cable ship Mackay-Bennett, which is located near Sandy Hook, some 20 miles from the greater part of the course, and connected with the shore by cables. It is also reported that the Naval Department of the United States Government has arranged with Signor Marconi to visit Washington and confer with Rear Admiral Bradford, Chief of the Bureau of Equipment, concerning proposed experiments to be carried on by officers of the United States Navy in wireless telegraphy. Some details of the apparatus may be of interest. Each station has a vertical conductor 150 ft. high, sufficient, it is estimated, for transmission over seventy-five miles, or twice the distance which will have to be bridged. The transmitting battery consists of ninety-eight dry cells, connected fourteen in series, and seven in multiple, and in parallel with eight storage cells in series, this arrangement being intended to give six amperes at about seventeen volts. The coherer consists of a glass tube about two inches long, in which two silver plugs a quarter of an inch long are tightly fitted and separated from each other by about one-thirtieth of an inch, the gap between them being partially filled with a mixture of nickel and silver filings, these metals having been found to be the most sensitive and reliable after a long series of experiments. The coherer is exhausted to a vacuum of four millimeters. In circuit with the coherer is a single dry cell and a telegraphic relay of the ordinary type. This relay is used to close the circuit of a local battery, which works a Morse writing instrument and also an electric bell hammer, which strikes the coherer a smart tap to restore it to its normal high resistance after it has received an impulse from the distant transmitter. To protect the coherer from the too powerful effects of the local transmitter the whole receiver is enclosed in a metallic box.

**An Organization of Dynamo and Motor Manufacturers.**—At the invitation of the Cutler-Hammer Manufacturing Company a meeting of representatives of the dynamo and motor manufacturers of this country was held in Chicago on the evening of Sept. 19th, another meeting being held the day following. The meeting was called for the purpose of forming a permanent organization. Although the purpose of the organization is not stated it is presumably to preserve more amicable relations in the competition for trade.

### Double Current Generators for Edison Stations.

The advantages of high-tension polyphase transmission now being recognized in connection with low-tension direct-current distribution, the problems involved in the generation of the high-tension power demand attention. In certain instances—where the generating station is within a district of congested loads—the generation of the polyphase currents is best combined with that of the low-tension power, especially if the daily peaks of the two loads do not occur at the same time, and one set of machines can be used to carry the peaks of both loads. Such an instance occurs in the system of the Chicago Edison Company, where so-called double current generators have been adopted, a description of which appears in the first article in this paper.

A peculiarity of these machines is that they are practically identical with rotary converters. Indeed the three-wire multipolar units, direct coupled to the steam engines and used for generating both kinds of current in the Harrison Street Station in Chicago are termed on their name plates "rotary converters," while the 4-pole machine not engine driven, but used only as a rotary converter, is styled a "three-phase continuous generator."

Where machines are used in this way for the simultaneous generation of both kinds of current, and particularly when two of them are coupled to the same shaft, some peculiar conditions arise in the problem of voltage regulation. Since the two dynamos of one unit are rigidly coupled to the same engine they cannot divide their a. c. load as do ordinary alternators according to the adjustment of the governors of their prime movers. Neither can the division of the a. c. load between them, when thrown in parallel on the a. c. side, be affected by varying the relative field excitation, since any difference between the a. c. voltages of the two would be immediately and automatically corrected by the interchange of wattless currents. Apparently the division of the load is determined once for all by the setting up of field rings of the two machines.

The a. c. sides of the positive and negative machines of one unit cannot of course be electrically connected in parallel as they are at different direct-current potentials, so they are in this plant magnetically paralleled by being connected to coils in the same step-up transformers. Even the machines of different units are not electrically paralleled on their a. c. low-tension sides as they might possibly be, but each unit is supplied with its own step-up transformers, the paralleling being done on the high-tension side.

Naturally some means must be provided to give an adjustment of the a. c. voltage independently of the d. c. voltage, and this is accomplished by means of induction regulators, one of which is inserted in the low-tension leads of each dynamo. A complete description and diagrams of the various regulating and controlling devices will be found in the article referred to.

### Floor Outlets in Large Offices.

The business man of the present day as a rule must have on his desk an electric light, a desk telephone, at least one push button and generally more, and in many cases one or more buzzers or bells connected with distant push buttons. Since the lighting wires must be isolated from the others, and the telephone companies generally prefer to have their wiring separate, this requires as a rule outlets at each desk from three interior conduits: one for the lighting, one for the telephoning and one for the signaling conductors. Where the desks are in small offices, adjacent to the walls, the problem is a simple one, as wall outlets can be fixed at a convenient height behind them, but where a large number of desks are in one large office room the case becomes more complicated.

In such offices it is generally now considered objectionable to bring down cords from the ceiling outlets or electroliers for the lighting service, so that all three classes of wiring must be brought up through the floor. Where the exact location of each desk room is known before the interior conduits are installed, the outlets can be properly located, but as a rule the layout of the office is not known or the plans are changed when the furniture is put in place. In this case at least some of the outlets are bound to come in passageways or under the feet of the persons sitting at their desks, and the wires leaving them will have their insulation

Digitized by Google

rapidly worn away by the constant tramping, or if made extra heavy will be likely to trip those walking past them. A case of this kind is described in the account of the wiring of the offices given in the second article in this issue.

---

Some better fixture is imperatively needed for such cases. The only solution that suggests itself with the apparatus now on the market is the use of many outlets scattered over the floor, one of which is bound to be in a suitable location for each desk, no matter what the arragement of the furniture may be, this outlet to be used and the others to be left closed.

---

**The Heating of Enclosed Motors.**

The occasional use of street railway motors for stationary work in exposed locations has proven so satisfactory that a demand has arisen for enclosed motors which has compelled practically all manufacturers to place on the market a line of such machines. This demand exists in spite of the fact that such a machine costs considerably more than an open motor of the same power. This is due to the fact that the enclosed motor gets no ventilation, and therefore cannot dissipate readily the heat generated on heavy loads, and must be rated at a very low load. The result is that a motor which will, when open, safely carry 15 h. p. will, if enclosed, reach the temperature limit with a load of about 10 h. p., and its rating when enclosed must be correspondingly reduced.

---

The only way in which the heat is dissipated from an enclosed motor is by radiation and convection from its exterior surface, there being no circulation of air through its parts. The surface must therefore be made larger if the motor is to be enclosed in order to carry away the heat, which otherwise would be dissipated by ventilation. In building an enclosed motor the armature, the commutator, the field magnets, etc., are made larger and correspondingly more expensive, solely to get an increased surface of the yoke ring and covers. As a rule the increased size gains nothing in the direction of a reduction of the heat generated within the machine, as is shown by the fact that enclosed motors are generally less efficient than open ones.

---

It would seem to be a far preferable plan to make the exterior of the motor with deep corrugations similar to those used for dissipating heat from enamel rheostats or theatre dimmers, or even more similar to the deeply corrugated rings of the cylinders of small unjacketed gasoline engines, such as are used in automobiles. These corrugations would greatly increase the superficial area of a given machine without increasing the size of its internal parts, and would almost correspondingly increase the heat which could be dissipated at a given temperature. Motors with deeply corrugated yoke rings of this kind are made by one enterprising house in Italy, and American manufacturers who now make their motors with practically a minimum ratio of surface to volume would do well to consider this plan.

---

**Long Distance Transmission of Power by Means of Gas.**

The attention of the reader is called to the remarkable signed statement of Mr. George Westinghouse, reprinted on page 472 of this paper, concerning the distribution of power to the sub-stations of long distance interurban or trunk line railways. The statement is made with a positiveness which, coming from such an authority, must carry great weight, that—where power is derived from fuel and transmitted long distances and distributed as direct current—it is preferable to drive the direct-current machines in the sub-stations by gas engines supplied by pipe lines from a central gas producing plant rather than to drive the same machines as rotary converters supplied by a polyphase transmission line from alternating current generators driven by the engines at the central source of power.

---

In other words, a central gas producing plant with pipe lines to sub-stations at distances of many miles is considered preferable to the transportation of the fuel in the solid form to these sub-stations and its use in a local gas producing plant at each. Furthermore, the gas pipe line from the central gas plant to distributed gas engines is considered preferable to centralized engines, generators, high-tension lines and step-down transformers.

---

It is interesting to see if the same conditions, which warrant the forecast of this revolutionary departure in power transmission for railroad purposes, apply to other lines of long distance work. Naturally they do not apply to the greatest number of long distance transmissions, viz., those driven by water powers. It has often been proposed to erect central power generating plants in the coal fields, especialy those of Pennsylvania, where enormous piles of low grade practically valueless coal, termed culm, now lie waste, but might be profitably utilized under boilers located near them, these boilers driving plants from which the power could be transmitted at high pressure to distant centers of population. If the opinion of Mr. Westinghouse is carrect (and his experience with all the factors involved must give it great weight), such transmissions would be better effected by generating producer gas from waste fuel and transmitting this by means of pipe lines to the distant centers of power distribution. All that has of late hindered the utilization of the enormous piles of waste fuel has been the fact that the loads are in the neighborhood of 100 miles away, too far distant for profitable transmission at voltages now available. The use of gas pipe lines may extend the range of profitable transmission far beyond that available electrically, in which case this utilization of a hitherto wasted bi-product may soon be realized. The existing transmission of natural gas from the gas fields in Indiana over considerable distances to Chicago gives an idea of the possibilities of transmission of this kind.

---

In central-station work also it is becoming customary to centralize the generation and transmit at high tension to rotary converters feeding the distributing system. The centralized generation is largely for the purpose of locating the plant on the water front where condensing water and cheap fuel can be obtained. If gas engines supersede steam engines for central station work, as they promise to do, the condensing water advantage of the water side location will vanish, and the fuel advantage can be retained by locating the gas producing plant at such a point and distributing the engines among the sub-stations. In the case of central-station distribution, however, there is, as a rule, no such great cost of transmission lines and great loss therein as in the case of such long distance work as that for which Mr. Westinghouse advocates gas engines, viz., suburban and interurban railways. However, there is apparently good reason to fear that large generating plants feeding rotary sub-stations may be shut down and superseded by gas engines driving the rotary converters direct.

## THE CONSTRUCTION OF SOME HANDY COMMUTATOR TOOLS.

BY ALTON D. ADAMS.

Direct current dynamos and motors have now come into very general use, exceeding in number, perhaps, steam, gas and oil engines combined. As is well known these electrical machines are subject to mechanical wear at only the bearings and the commutator, which have to be replaced from time to time. The very general demand for dynamos and motor repairs has been met to some extent by electric repair shops that have come into existence at many points through the country, but aside from these there is hardly a regular machine shop of any size that is not constantly called on for more or less work on the worn parts of dynamos and motors.

As bearings in electrical machines are usually fitted with bronze bushings, with standard reamed holes, well equipped machine shops are usually in position to make these parts, but in the matter of commutators there is not one regular shop in fifty with the simple tools necessary for their renewal, and the average machinist has but slight conception of how this work must be done to insure satisfactory results.

In electrical repair shops there are usually some tools for handling commutator work, but they are frequently of the crudest kind and such as to require too much labor, and even then lack certainty in results. Some even among dynamo and motor manufacturers lack the few and simple tools necessary to insure first-class commutator construction with a minimum of labor. As usually constructed, a commutator contains a number of copper "bars" or "segments," separated from each other, and the clamping parts by mica strips and rings. These bars are parts of true circular sectors, though not of the exact circle of the commutator surface, and are held, with the intervening mica strips, by a sleeve and clamps.

Some of the main requirements of commutator construction are that each segment be insulated or free from metallic contact with any other or the sleeve and clamps, that each segment be so firmly held that the forces of expansion, due to heat when the machine is in use, shall not alter its relation to the other segments, and further that the relative position of segments and mica strips shall remain the same after the commutator has cooled.

Were all parts of commutators metal, the above requirements would make careful work necessary, but as each segment must be held entirely by contact with mica, the problem is much more difficult, in fact, it has required more study and experiment than any other mechanical question that electrical manufacturers have had to meet.

Mica has come into very general use for commutator insulation because of its high insulating properties, non-injury by heat and power to sustain great pressures with but small compression. On dynamos and motors of moderate capacity in common use the number of commutator segments varies from six or eight to about two hundred according to the purpose and capacity of the machine, the most common numbers of segments being from twenty-four to one hundred.

As for every segment there must be a strip of mica, in addition to the mica rings, the number of separate parts that must be held in their exact position in a commutator will vary from fifty to about four hundred in machines of moderate capacity and common use. In order to hold so many pieces of materials, to a large extent contrary as to their qualities, rigidly together, it has been found

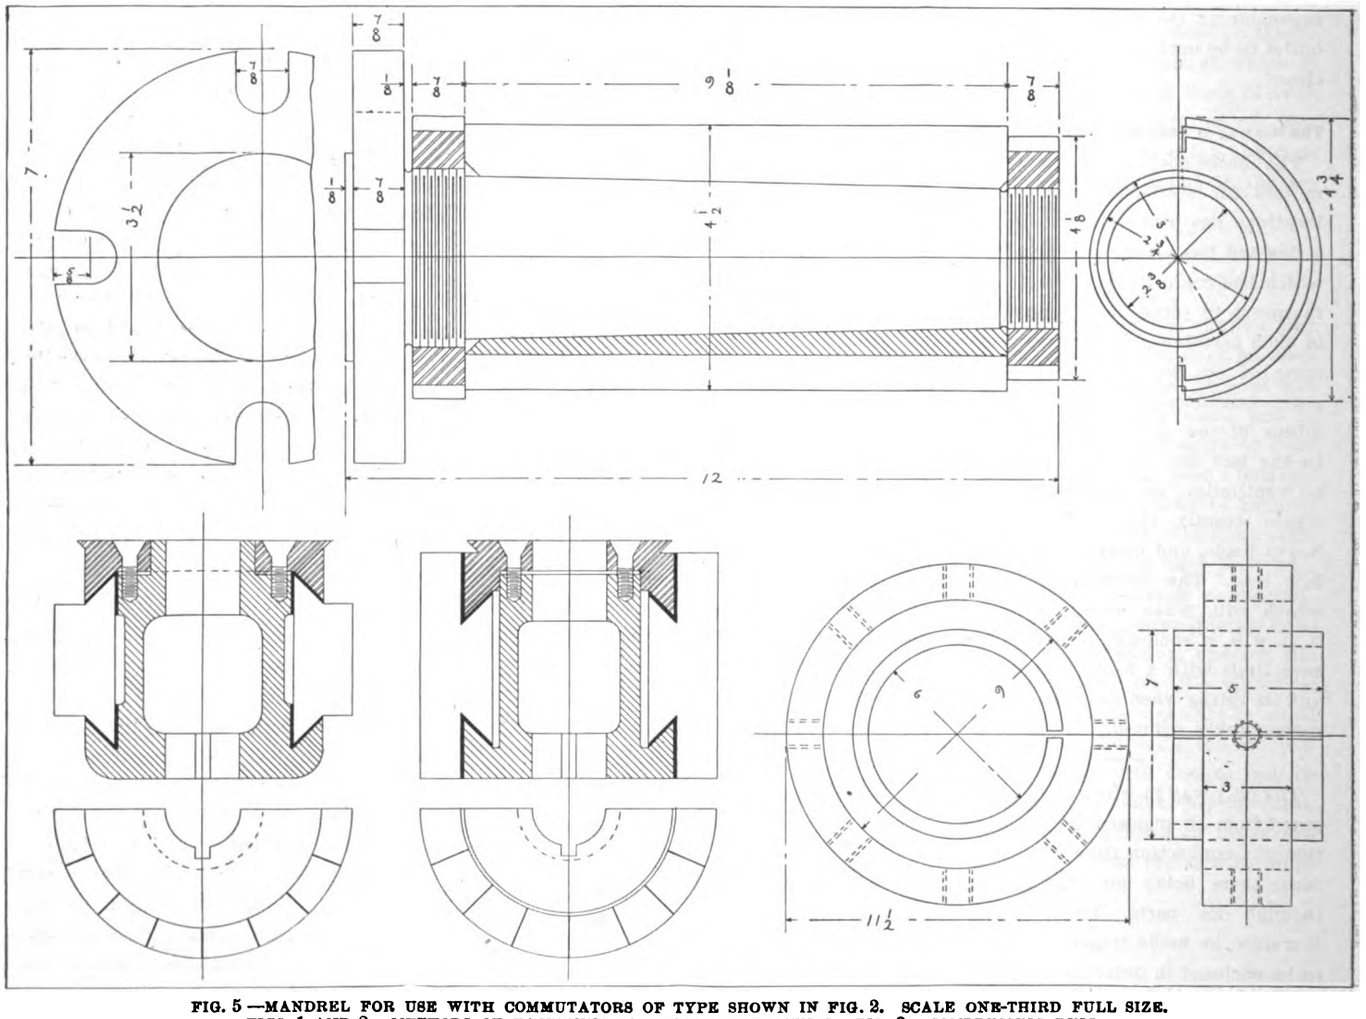

FIG. 5.—MANDREL FOR USE WITH COMMUTATORS OF TYPE SHOWN IN FIG. 2. SCALE ONE-THIRD FULL SIZE.
FIGS 1 AND 2.—METHODS OF FASTENING COMMUTATOR SEGMENTS. FIG. 3.—COMPRESSING RING.

Digitized by Google

necessary to assemble them with great pressure, and then set the permanent clamps as tightly as possible before the external pressure is removed.

The two most common and successful methods of clamping commutators are shown in Figs. 1 and 2, the solid black lines in each case representing the mica strips and rings. The better class of segments are forged or of drawn stock, so that no labor is required on the sides before assembly in the way shown. As soon as assembled it is necessary to compress and hold the segments securely so that the surfaces which come in contact with the mica rings may be machined.

A method to compress and hold the segments, common in many electric repair shops, and with some manufacturers, employs a solid forged ring turned on the inside to the diameter which the segments are estimated to have when compressed, and tapered slightly at one edge so as to start easily over the segments. In the correct use of this ring it should be forced over the segments with a pressure of some tons, as this source of pressure is the only one to bring the segments and mica strips solidly together. To do a good job with this solid ring a hydraulic or large screw press is necessary, and in many cases machine and repair shops are without either of these presses, so that the ring can only be forced on and off the segments with a hammer, a very unsatisfactory method. A serious objection to this solid ring method is that it is very hard to estimate the exact diameter to which the ring should be turned in order to properly compress the segments, and the trials to see how hard the ring crowds on all take time. Again a solid forged ring must be had for every size of commutator, even though they vary by only a small fraction of an inch in diameter, and there is great temptation when a ring goes on too easy to let it go as "good enough." To do away with the necessity for presses, also forged rings for every commutator, save time and insure means for the desired compression in every case, the tool shown in Fig. 3 is now much used.

This tool consists of two rings, the outer a solid forging and the inner an iron casting, split along one side so that its diameter may be slightly changed.

The outer forged ring is fitted with six, eight or more radial set screws, which bear upon the inner split ring. The commutator segments and mica strips having been assembled in circular form, the split cast-iron ring, having been turned as near as possible to the correct diameter, is pushed over them and pressure applied by means of the large set screws in the forged ring. Any desired pressure can be obtained by the combined action of the heavy set screws, the split ring readily conforming to the slightly reduced diameter of the segments. The work can also be done much more quickly than when a solid ring and press are used. It is not necessary to have one of the above tools for each size of commutator, as only the inner cast ring need be changed until the commutator diameters vary by as much as three inches, so that the forged ring becomes either too small or so large as to be unhandy. In this way two or three forged rings will cover a large line of commutators, while the cast ring for each commutator is cheaply and quickly made.

When the segments are securely clamped in the ring the next step is to turn up the surfaces to which the mica rings transmit the pressure of the permanent clamps. In most machine and electric repair shops the lathe chucks are the only means for holding the clamped commutator segments while the surfaces at each end are machined, and here comes a waste of time and inaccurate results due to the effort, after one end of the segments has been turned up to reverse them in the chuck, so as to machine the other end in line with the first. The tendency with work done in this way is to force the permanent clamps slightly out of line with each other, and this may result in loose segments at some point in the commutator. Proper expansion mandrels, as shown in Figs. 4 and 5, not only enable the finished surfaces at the two ends of the segments to be brought practically into line, but also save much time on the work.

Fig. 4 shows a mandrel adapted for use with segments of the type in Fig. 1, where there is no undercut work to be done, while the mandrel of Fig. 5 is more convenient for undercut segments. The mandrel of Fig. 4 mounts in the usual way on lathe centers, has a taper of one in twenty-four, is fitted with cast-iron expansion sleeve and a screw collar at each end, to force the sleeve on and off. The cast-iron sleeve should be cut entirely through once along its entire length, and nearly through, say, to within one-fourth or three-eighths inch at three or more other points, that it may expand as evenly as possible when forced onto the mandrel.

A sleeve for this mandrel should be turned outside to correspond with the inside diameter of the commutator segments it is intended to mount, and if very accurate work is desired the inside of segments should be turned out before mounting them on the expansion sleeve, though some makers think this unnecessary. When the segments are mounted on the sleeve this latter is expanded by forcing it on the mandrel with the screw collar, and the ends of segments in Fig. 1 can be turned up without changing their position.

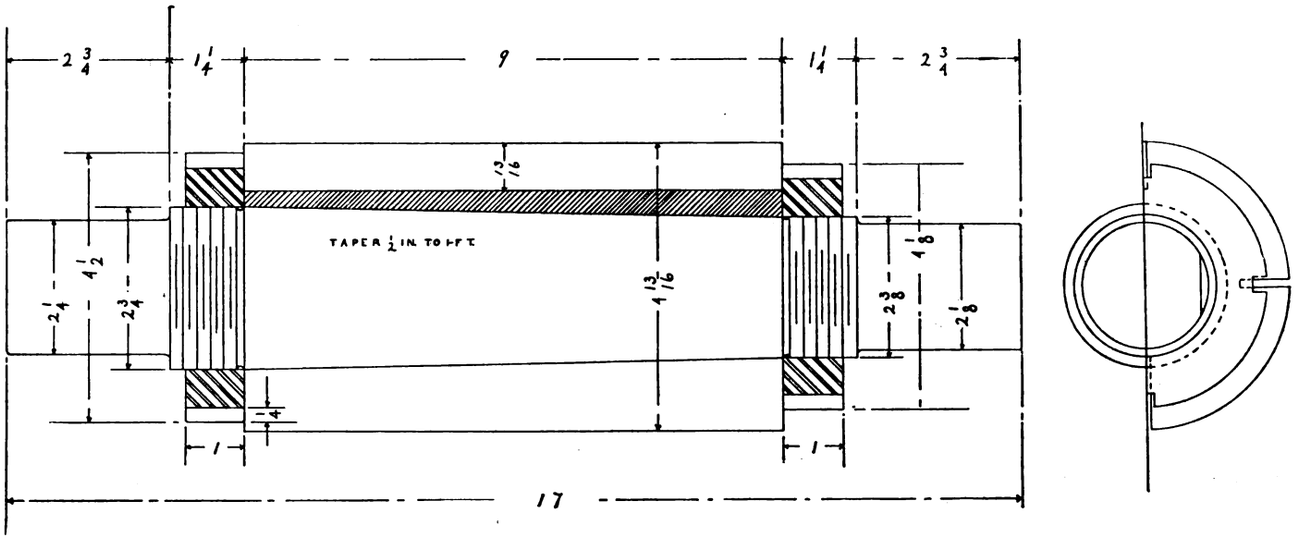

FIG. 4.—MANDREL FOR USE WITH COMMUTATORS OF TYPE SHOWN IN FIG. 1. SCALE ¼ FULL SIZE.

The segments shown in Fig. 2 can also be turned on the above mandrel, but the work on the undercut is done at a disadvantage and much time can be saved by the use of the mandrel of Fig. 5. This mandrel, like the other, is on a taper and fitted with expansion sleeve, but one end is forged into a flange, adapted to bolt to a face plate and allow free access to one end of the commutator segments, so that the undercut can be made quickly. One end of the segments being finished, they are forced off the mandrel with the sleeve by the screw collar, and then put on again reversed and the other end finished. There is, of course, no reason to take the man-

Digitized by Google

drel from the face plate until both ends of the segments are finished, so that time is saved and the finished surfaces brought very nearly in line. Quite a number of expansion sleeves can be used on the same mandrel for different commutators, so that two or three mandrels will be enough for a factory turning out a fair line of machines.

Having turned up the ends of the segments, it is next necessary to mount them on the insulating rings and permanent clamps. As segments are held only at the finished surfaces, it is necessary that each make solid contact with all of the mica rings, as the side pressure of the other segments is not sufficient to prevent motion either up or down. The double ring clamps are of special value when the segments are to be brought to a firm bearing on the mica rings, since, when necessary, the set screws can be let up a little in order to allow the segments to slide over the horizontal mica rings, and then set up until each segment beds firmly on the mica. The permanent clamps once in place, the outside rings are removed and the surface of the segments finished up, first by turning with a diamond-pointed tool and later with a single cut file or the finest grade of sand paper.

It may be well to add the oft repeated warning that emery cloth should never be used on a commutator, as the emery sticks in the copper.

The above simple and inexpensive tools will multiply several times the amount of commutator work a man can turn out daily with the devices now common in some shops devoted to the repair and even the manufacture of electrical machinery.

## AMERICAN TELEPHONE PRACTICE.

### TESTING.*

BY KEMPSTER B. MILLER.

One of the principal uses of the galvanometer in line testing is in the measurements of insulation resistance. The insulation resistance of any line or conductor is the joint resistance of all the leaks from the line to the ground or to other conductors. On a pole line every insulator forms a leak to earth, and on a line having 40 poles to the mile there would be 40 such leaks in parallel. The insulation resistance of a line as a whole varies inversely as its length, if the insulation is uniform. Evidently, a line two miles long would have one-half as great an insulation resistance as a similar line one mile long, because on the latter there would be only half as many leaks as on the former. In general it may be stated that a line n miles long will have only $\frac{1}{n}$ as great an insulation resistance as a similar line one mile in length. In order to obtain a standard of insulation resistance independent of the length of the line, it is convenient to express the insulation resistance as so many megohms per mile. The insulation resistance per mile is found by multiplying the insulation of the line as a whole by the length of the line in miles.

In order to measure the insulation resistance of a line the constant of the galvanometer is first taken and the known resistance is cut out of circuit and the line insulation resistance substituted for it. Assuming that the insulation resistance to be measured is that of a wire in a cable, the terminals of the circuit which should be connected with the resistance to be measured, will be connected one with the wire and the

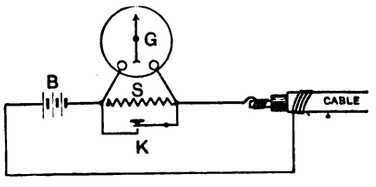

FIG. 1.

other with the sheath of the cable as shown in Fig. 1. Care must be taken that the wire being measured is carefully insulated from the sheath at the other end of the cable. The shunt, S, is then cut out of circuit in order that the full current may pass through the galvanometer. Before completing the circuit with the cable conductor and sheath, however, the key, K, should be closed in parallel with the galvanometer, in order to prevent the rush of current that will take place in charging the cable, from causing the needle to give too violent a kick. After a short time the key is opened and all of the current diverted through the galvanometer. The galvanometer then receives only that current which leaks from the core of the cable to the sheath through the insulation. Under these circumstances a certain deflection will be noted, and by comparing this de-

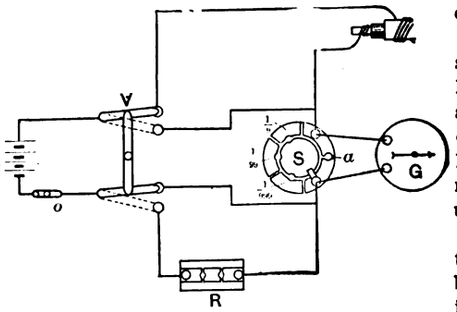

FIG. 2.

flection with the constant already obtained the value of the insulation resistance in megohms is readily determined.

To illustrate, suppose that a deflection of 75 scale divisions is obtained with the apparatus connected as in Fig. 1. If the constant is 20,000, as already determined, we know that the insulation resistance must be 20,000 divided by 75, or 266 megohms, thus indicating that the total insulation resistance of the cable is 266 megohms. That this is true is evident from the fact that the constant, 20,000, represents the number of scale divisions deflection that would be obtained were only one megohm in the circuit. The deflections are inversely proportional to the resistance in the circuit, and therefore the total insulation resistance is equal to the deflection through one megohm divided by the deflection through the insulation resistance, or 20,000 divided by 75. To sum up these operations:

1st. Obtain the galvanometer constant or deflection obtained when the galvanometer in series with one megohm resistance is subjected to the potential of the battery. 2d. Find the deflection obtained when the galvanometer and insulation resistance in series are subjected to the potential of the battery. 3d. Divide the constant by the deflection obtained through the insulation resistance, the result being the insulation resistance of the cable expressed in megohms. 4th. To find the insulation resistance per mile, multiply the total insulation resistance by the length of the cable in miles.

In Fig. 2 is shown a convenient arrangement of connections for making insulation tests. In this, B is the battery of say 50 cells, R the 1/10 megohm box, S the shunt box, G the galvanometer and V a convenient switch for throwing either the 1/10 megohm box or the line insulation into circuit with the galvanometer and battery. When the levers of the switch, V, are in the position represented by the dotted line, the circuits are those for taking constant of the galvanometer, and when in the position shown by full lines, the circuits are those for obtaining the deflection through the insulation of the cable. Various forms of keys for changing the direction of the battery current through the galvanometer, and for performing other switching operations with the greatest possible convenience, are obtainable, and form an important part of all testing outfits. The scope of this work will not permit of their detailed description.

In making the insulation tests the resistance of the lead wires to the cable or line need not be taken into account. It is a matter of the greatest importance, however, that these wires are perfectly insulated from each other. It is a very easy matter in testing of this nature to measure the wrong quantity.

One very important matter in connection with insulation tests has not yet been spoken of. When the reading is being taken, with the cable or line insulation in circuit, it will be noticed that a maximum deflection is obtained at first, and that this gradually diminishes, as though the insulation resistance were increasing. This is due to what is called electrification, a phenomenon that is not very thoroughly understood. When the electromotive force of the battery is first applied to the cable or line, there is a sudden rush of current, due to the charging of the conductors. The charges, however, apparently soak in to the insulation to a slight extent, thus allowing more current to flow to the conductors. After the first rush due to the first charging of

* From a book to be published by the American Electrician Company.

Digitized by Google

the conductors, there is still a flow of current, due in part to this soaking in, and in part to the actual leakage through the insulation. It is the current due to the latter that we are concerned with in insulation measurements, and therefore we must wait till the soaking-in process ceases, when the flow of current will be practically constant, being that through the insulation. In nearly all telephone-testing work, one minute is allowed for electrification, after which the reading is taken of the deflection. When one is thoroughly familiar with his instruments he may often, where great accuracy is not required, estimate what the deflection at the end of one minute will be, by watching the deflection for 30 or 40 seconds. This method saves time, but must be used with extreme caution.

With a constant of 20,000 a reading taken on a wire in a piece of good new telephone cable, one-quarter mile long, would probably show a deflection of 8 or 10 scale divisions upon the closure of the key. This would decrease to about 6 scale divisions in 2 seconds, and to about 2 scale divisions in 30 seconds, after which it would remain constant. The reading of 2 divisions at the end of the minute would indicate an insulation resistance of

$$\frac{20{,}000}{2} = 10{,}000 \text{ megohms}$$

or 2500 megohms per mile.

As an example of a deflection on a wire in a representative cable the following is given:

Dry paper cable, ¾ mile long, two years old. Galvanometer constant 22,000: Readings, 12-15-15-10-10-15-15-15-13 scale divisions.

## INTERIOR WIRING.

### OUTLET BOXES.

BY CHARLES E. KNOX.

One of the recent additions to the requirements of the National Board of Fire Underwriters was that in regard to the use of outlet boxes. Previous to that time they were used in the larger and more important installations, but in the majority of cases their use was dispensed with. The rules passed by the National Board covering outlet boxes are as follows:

Rule No. 25d. (Interior Conduits). Must be equipped at every outlet with an approved outlet box.

Rule 25e. Metal conduits, where they enter junction boxes, and at all other outlets, etc., must be fitted with a capping of approved insulating material, fitted so as to protect wire from abrasion.

The wisdom of passing the former rule is beyond question; the latter is open to discussion. We will consider this more fully after describing outlet boxes and their advantages, in a general way, and after that the various forms and types of outlet boxes.

An outlet box is a metal box, usually in two parts (box and cover), placed at an outlet, to provide a terminal for the conduits, and also a space for making the connections between the branch circuit wires and the outlet fixture or appliance.

Their advantages are: 1. That in no other way can such a satisfactory terminal for the conduits be obtained. 2. The connections between the fixture and the branch circuit wire can, with the use of outlet boxes, be made in a space protected from plaster, dirt, etc. 3. By their use it is possible to make a neat finish, with plaster, wood, etc., around the outlet opening, which would be impossible without their use. 4. The boxes being insulated inside, the possibility of "ground" or "short circuit" is greatly decreased at the points where these troubles are most apt to occur. 5. By their use, particularly in the case of side outlets, a suitable support for the fixture is more easily obtained.

As to the rule of the Fire Underwriters requiring "a capping of approved insulating material fitted so as to protect the wire from abrasion," it would seem to be both unnecessary and undesirable in a properly designed outlet box. If arrangements are made in the design of the outlet box to receive the conduits in a proper manner and to prevent the conduit from coming beyond a proper distance into the box, it would seem impossible for any abrasion or injury to the wire to occur, because owing to the confined limits of the box it would be impossible to bend the wire sharply over the end of the conduit. If, however, no means be used in the outlet box to prevent the tube from projecting more than a slight distance into the box, it is easily conceivable that such abrasion of the wire may take place. Where the tube is allowed to project any considerable distance into the box, it is apparent that in order to bring the wires from the opening of the tube to the proper point (presumably the center of the outlet box opening), friction of the wire against the tube and consequent injury to the wire are very apt to happen. It would seem that the proper way to prevent any such abrasion to the wire insulation would be to adopt means to prevent the conduit from projecting into the outlet box beyond the proper point. Another objection to the use of this "capping," or "outlet terminal," is that the outlet box would probably have to be increased in depth to receive it, which would be objectionable.

The first iron outlet boxes used with iron-armored conduit consisted of a hollow iron casting, in one piece, about four inches square and one and a half inches deep, with an opening in the front face, and having one of the sides open to receive the conduits. If conduits entered the box at any other side, openings in the box were made to receive them. This box had many disadvantages. In the first place it was clumsy; it made no provision for tubes entering it on more than one side, and it was necessary to fill up the large opening around the tube to prevent plaster and other materials from falling into the box itself. It had other disadvantages, which will be apparent from the discussion of the present forms of outlet boxes given below.

All the outlet boxes now manufactured may be roughly classified (like men's clothing) in two groups, viz., first, "ready-made," and, second, "made to order." Under the first head are included those forms of boxes usually designated universal outlet boxes, in which provision has been made so that an opening may be made more or less readily in any part of the box so that, no matter in what direction the tube comes, a corresponding opening in the box may be made more or less readily without drilling. The other type of box is one in which openings are already made at certain points for the conduits to enter. Let us now consider the various forms of both types of outlet boxes in detail.

Figs. 1, 2 and 6, page 480, drawn steel outlet boxes of the first (universal type). Figs. 3, 4 and 5 show cuts of drawn steel boxes which may be used as universal boxes by ordering boxes of the designs as shown, but with the maximum number of holes and having all the holes plugged with steel plugs.

Figs. 7 to 15, inclusive, show boxes each of which is designed for a particular case, and is not intended to be used under any other conditions than those for which it was designed.

The advantage of the universal type is apparent. When these boxes are used it is only necessary to state in ordering whether round or square boxes are wanted, and whether for gas and electric fixtures or electric fixtures only. Again, in these boxes the tubes may be brought into the box from any side, as it is possible to make an opening in any of the four sides or in the back; also, if the work be changed or if outlets be omitted, the boxes are good for future work, as they can be used under pretty nearly all conduits. Their disadvantage is the same as that which is, and always will be, the objection to all universal tools, namely, that they are admirably adapted for all cases but very poorly suited to any one particular case. It is always necessary in making a thing suitable for all cases to compromise several points in order to make the tool or appliance suitable for all conditions.

The advantage of the other type of boxes is that each box being designed for a specific purpose, it is especially arranged for those conditions, and much neater and better work is attained by their use, their disadvantage being that a little more trouble is involved in ordering. We will now describe in detail each of the boxes shown in the cuts.

Fig. 1 shows a square box and cover having two plugged openings on each of two opposite sides and one plugged opening on each of the other sides. The openings in the boxes have threaded sleeves to receive the conduit. It is questionable whether threading the sleeves is necessary. It certainly adds considerable to the cost of installing the conduit in the box, as it is necessary to put a thread on the conduit and screw the conduit into the box. Each of the plugged openings in this

box may be removed by striking the plug with a hammer. Fig. 2 shows a round box and cover with four plugged openings in the side. As will be seen, these openings are not sleeved or tapped. The cover of the box has projecting lips, which are tapped to receive screws for receptacle or wall socket.

Fig. 3 shows a square outlet box with a tapped sleeve opening on each of the four sides. These openings are not plugged, but may be plugged if so ordered. This box is provided with a threaded sleeve for supporting the electric fixture. Fig. 4 is somewhat similar to No. 3, except that it has openings on only two sides, but has two openings in the back to receive tubes coming from the rear. It is also provided with a small section of tubing screwed into the back of the box, through which the gas pipe is intended to pass. Fig. 5 shows a steel outlet box for push-button switches. This box has two tapped openings at each end and one at each side. These holes may be plugged or not, as desired. The slotted openings through which the screws fastening the cover to the box pass are intended to allow for adjustment of the box cover so that the switch cover may be made absolutely straight, even though the box itself be crooked. The switch cover, of course, is fastened by machine screws to the flanges shown at top and bottom of opening. Fig. 6 shows an outlet box with several plugged openings, which are prolonged to the top of the box. This has an advantage which will be mentioned hereafter.

Fig. 7 shows a square cast iron box and cover with two openings in the one side. The tapped holes in the bottom are for securing the flanged stem swing for the fixture support. As will be seen from a close inspection of the cut, the box and cover are split so that the division occurs through the center of the openings. This makes it very much easier to install the conduit and box, as the rear portion of the box may be secured in position, the conduit installed and then the cover fastened in place. The box is also provided with a "stop" (not shown in the cut) which prevents the tube from projecting too far into the box. This stop consists of a short stud, cast in the box, which is prolonged just far enough to stop the edge of the tube without interfering with the tube opening. Fig. 8 shows a similar box designed to receive a wall socket instead of an electric fixture. Fig. 9 shows a round box and cover with openings in the back. This is generally used for a ceiling box, as conduits for outlets in the ceiling usually come in the rear of the box. The tubes in the case of these boxes are prevented from projecting too far into the box by means of the flanged nut, shown in Fig. 16. This nut is fastened by means of a set screw to the fixture support or gas pipe, which passes through the central opening in the box. In some cases the nut is tapped inside and is screwed on the fixture support or gas pipe. Fig. 10 shows a ceiling box with two openings in the back and with a receptacle, lamp and shade complete. The brass canopy screws to the box itself. This box is made in the shape of a truncated cone, so as to give the minimum possible opening in the front, thus reducing the necessary size of the canopy. Fig. 11 shows another form of ceiling box adapted for a drop-cord rosette. Fig. 12 is a box designed for an elevator cable. The tube enters the side of the box, the

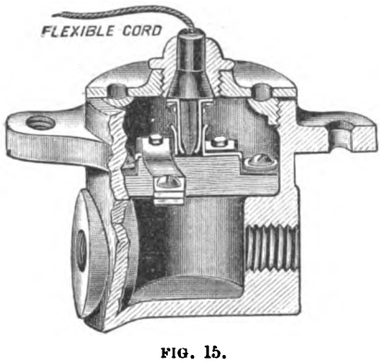

FIG. 15.

connections between the elevator cables and the branch circuit wires being made in the box itself, and the cable passing out through the nose on the cover. Fig. 13 shows a special outlet box designed for the purpose of bringing wires through an outlet in the floor to make connections for a light on a desk or a table. The tube is threaded into the side of the box, as shown, the conduit thread being filled with white lead so as to make a thoroughly watertight joint, the same as is made in gas piping. A connecting block is placed above these two openings, where connection between the concealed wires and the fixture wire running to the table may be made. The fixture wires then pass through a conduit screwed into the cover, which has a threaded stem to receive the same. The lugs on the side of the box

FIG. 16.

serve for securing the box to the rough flooring. The cover fits flush with the finished floor, the floor being bored so as to make a snug fit around the box cover. In case at any time the connections between the floor outlet and the fixture on the table or desk is not needed or wanted, the conduit wires and cover may be removed and replaced by a flat cover with no opening in the top. The box then presents the appearance shown in Fig. 14. This cover fits flush with the finished floor. Fig. 15 shows a means whereby the conduit may be dispensed with and the connection between the floor and table may be made by means of a plug and a cable.

## VALVE REPAIR TOOLS.

As stated on page 427 of the September issue of the American Electrician, the Dexter valve reseating tool has been greatly improved, the improvement in question consisting of an arm attached to the circular frame of the machine, which carries the cutter. This arm carries a sliding bracket and a dead center, as shown in Fig. 1 on the following page. The result of this arrangement is obvious, it being greater steadiness of the disc and less strain on the chuck. The bracket arm for cutting flat discs is also a part of the outfit, as also is the extension for use in cutting discs which are cast solid on the valve stems.

The valve disc is securely fastened to the small chuck, 4, on the machine spindle, and is given a rotary motion by turning the crank, 7, with one hand, while the pointed tool is fed slowly over the disc with the other hand. The pointed tool or cutter is adjusted by the feed screw, 2. To cut a flat disc, the holder, 13, is used, the extension, 3, being used for recutting discs that are cast solid on valve stems. As above noted, this extension becomes necessary in order to obtain the distance required for the operation.

A peculiarly compact form of Block Chuck Valve Reseating Machine is made by R. H. Benton, 23 Vandewater Street, New York, and illustrated herewith by Fig. 2. This may almost be termed a "Vest Pocket Machine," it is so simple and small. A two-jawed "universal" chuck is used for engaging the thread in the bonnet opening, and a sleeve in the chuck carries the cutter spindle and milling discs, as shown in the engraving. The crank is made double. For large valves it is rigged as shown, but for small ones the stem is put into the hole nearest the handle.

This tool will reseat valves from three-eighths to twelve inches in diameter, and is intended to handle not only regulation bevel seated valves, but to take care of flat seated valves, flat checks, taper checks, flange valves and water faucets. The apparatus for handling discs is shown at the left of the engraving. It is a sort of yoke which is attached directly to the universal chuck, and, the disc being placed on the cutter stem in place of the cutter bar, the metal is trimmed off in a hurry, a positive feed being used, as described for seats.

Special forms of regrinding tools are sometimes sent out by valve manufacturers to be used when the seating surfaces have, from accident or neglect, become so badly cut or worn that the usual regrinding has not enough effect thereon. Fig. 3 shows a seat reamer made by the Lunkenheimer Co., Cincinnati, O., for use with its valves. As shown in the left-hand cut, the reamer is put in place of the disc, which is temporarily removed for that purpose. For valves below one inch the solid steel reamer, shown at right of cut, is preferable. Care should be taken in reseating

Digitized by Google

valves to take no greater cut than is absolutely required to form a new bearing. It is expected that the discs in connection with this machine are not to be reground, but replaced by new ones as they become damaged or worn out.

The manufacturers claim that these tools are not necessary when their valves are kept tight by frequent and judicious regrinding, when the leakage is only slight, then the usual percentage of regrinding with some abrading material being all that is necessary; but when the valves are subjected to very hard service and become badly worn or cut, then the tools described are valuable, and should be used at once. In using the reamers with T handle, the trimming of the valve is removed and the reamer inserted in its place. On the other sizes the loose valve disc can be removed and the reamer inverted so that the hub guides in the body while the new seat is being cut, thereby making sure that it is always in line with the stem.

These cutters are practically indestructible, as they can be sharpened any number of times without changing their form.

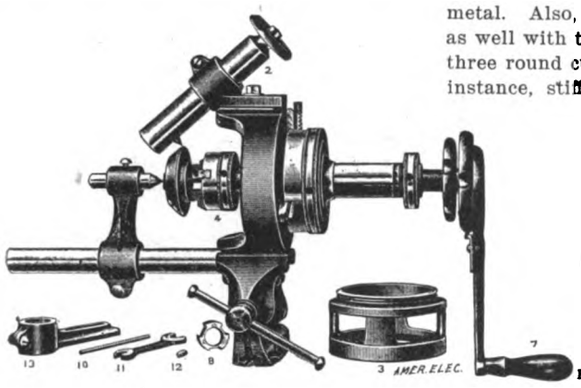

FIG. 1.—IMPROVED DEXTER DISC CUTTER.

The brass discs, or stems, should in all cases be renewed as they wear out. Their cost is very small, and a loose fit there would not be economical practice; hence they should be freely renewed.

A combination machine for reseating all kinds of valves and cocks is shown by Fig. 4. The engraving shows the long taper plug of a cock in the machine, and on solid disc valves it is not necessary to remove the hand wheel. The all-round steel milling cutter is used. Although the engraving gives a good idea of this machine it should be seen in operation in order to obtain a full idea of its capabilities. The action of the three cutters on the face plate cannot well be described to one who has never seen the machine in action. But it can be readily comprehended that round steel cutters will do better work than straight pointed tools which cut at one point only. This is granted by all mechanics, and proved by the milling machine, and also is found to be the case in valve reseating, the pointed tool is apt to cut away too much metal. Also, the work is not supported as well with the pointed tool as when the three round cutters are used. In the first instance, stiffness of the valve or stem must resist the entire side thrust of the cutting tool, but with the round cutters there is no side thrust, the work being equally supported from three sides at once. From three to six taper plugs are all that will be required for the ordinary sizes of valves in an electric light station. The base of the machine may be screwed in a vise during action, or it may preferably be screwed to a table or bench; or it can be used when a disc is placed upon it the truing or centering operation may be quickly done by bringing the cutter against the work, and allowing the whole business to revolve until the disc runs true. Then the set-screw shown on top of the tail-stock may be tightened and the grinding act proceeded with.

This machine takes care of discs, and also by interchanging the gears and cutters, and using a part of the machine, it may be used for ordinary stop valves also. As shown by Fig. 6, the milling cutter is driven by bevel gears, and they are pivoted on a head block, which is centrally adjusted and held in place by a hub with radially adjustable jaws. The cutter is set up to its work by means of a wedge forced down by a screw, shown at the left of the engraving, which bears against the other valve seat.

This machine, as set up for milling gates, as shown by Fig. 6. The gate is held in position by the hub before mentioned, which is secured to the tail stock, while the cutter is turned and fed up to its work by the crank and hand wheel in a manner that has already been described.

A very ingenious, yet comparatively simple, device for reseating all sizes and types of gate valves, wherein the same mechanism is used on both gate and seat, is the subject of illustration in Fig. 7. It is a machine also made by Hall, Son & Company, as described above. The cutting is done by a regular milling cutter

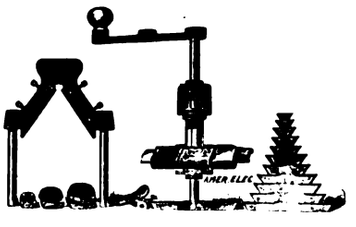

FIG. 2.—BENTON BLOCK CHUCK VALVE RESEATING MACHINE.

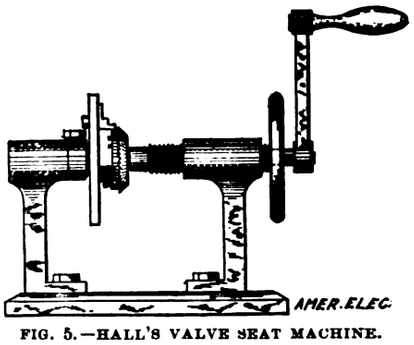

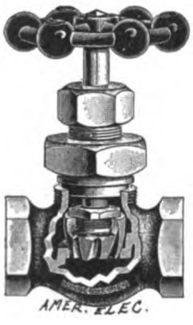

FIG. 5.—HALL'S VALVE SEAT MACHINE.

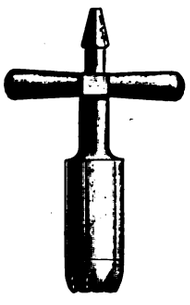

FIG. 3.—LUNKENHEIMER STEEL SEAT REAMER.

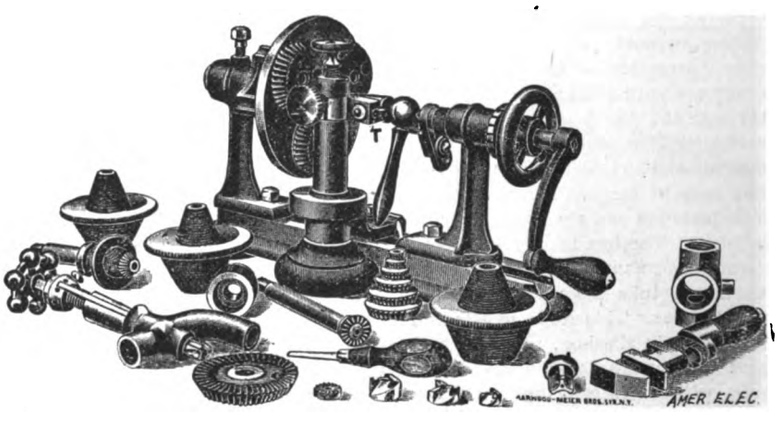

FIG. 4.—HALL COMBINED RESEATING MACHINE.

Digitized by Google

which is attached to a rigid frame, and put inside the valve and bolted thereto. Means, not clearly shown in the engraving, are provided whereby the cutter is fed up to the seat. In milling the gate the same mechanism is employed as with the seat, and the gate is placed in a jig which approximates the opening in a gate valve. Then, by means of a suitable clamp, the cutting mechanism is affixed thereto, and the cutter is fed up by means of a screw, shown at D. Some attachments are also shown for attaching the tool to valves of special construction.

One point of the Hall machine is worthy

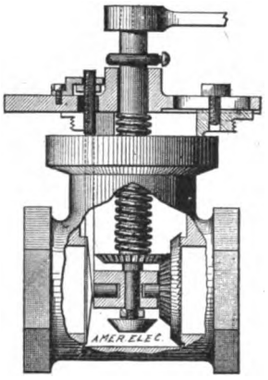

FIG. 6.—ARRANGED FOR GATES.

of especial notice—the machine for reseating plugs and blow-cocks. This device uses the frame and stand shown in the last engraving (Fig. 7), and as presented in Fig. 8, will be seen to resemble that device closely, with the exception of the face-plate which carries the three circular cutters. Fig. 8 shows a plug in the machine at D, and the cock tie at J, with the adjustable reamer in place ready for work. It will be seen that motion is imparted to the reamer by means of the hand-wheel, M. By turning the nut, K, by means of a wrench, the taper of the reamer may be altered to fit the valve to be repaired.

There are three adjustable cutters in this reamer, as shown at I. and also at P, P, in another portion of the engraving. The required taper of the plug is readily obtained by setting over the head and tail stocks and by means of the adjustment already described, the hole may be reamed to fit the plug. Or the hole may be made and the plug fitted thereto, as may be desired. The cocks may be repaired by this machine without removal from their places in the piping.

An improved and very simple form of standard valve reseating machine (by F. S. Dangerfield Co., Auburn, N. Y.) is shown by Fig. 9. A triangular face plate chuck is used for holding a disc while the circular cutter fitted to that particular disc is brought into use. This tool, of which No. 2 is shown in the illustration, is placed on the market in ten sizes and will reseat all globe, angle, gross and

safety valves, drop, swing and ball check valves, Jenkins', Fairbanks', Crane's, Lunkenheimer's, Powell's and all other makes, both flat and taper seats, with screw or flange caps from ¼ to 12 inches inclusive, also faucets, without removing the valves from the pipes, making them absolutely steam tight.

### A Ground Detector for Three-Wire Systems.

*To the Editor of American Electrician:*

Sir.—Allow me to suggest an arrangement of lamps for a ground detector on a three-wire system which will indicate a ground on any of the three wires without endangering the lamps. The diagram shows three lamps connected in series on one side with a ground through a push

button between the lamp nearest the neutral and the next one, and by tracing it out for different conditions it will be found to indicate differently for a ground on any one of the mains. I find it useful on systems where the neutral is not permanently grounded.

# Electrical Catechism

*346. Of what material is the field magnet of a motor usually made?*

Wrought iron, cast iron and cast steel are used. Wrought iron has higher permeability than either of the others; this allows the magnetic field to be made more dense, and therefore the whole machine may usually be made smaller for a given power. Cast iron costs less per pound and can be cast into the required shape more cheaply than wrought iron can be forged or punched. Cast steel, containing but a very small percentage of carbon, can now be obtained in any desired form of casting, and is rapidly displacing cast iron because its magnetic properties are almost as good as those of wrought iron, while it costs but little more than cast iron. For very small motors, hardened tool steel is sometimes used, being permanently magnetized so that no field magnetizing coil is necessary.

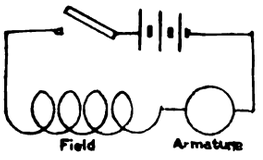
*347. How is the field of a motor usually magnetized?*

The hardened steel magnets sometimes used with small motors are magnetized by being placed between the poles of a strong magnet or by passing a strong current through a coil placed temporarily around the hardened steel. It is more common to magnetize the field by current through a coil, which is part of the motor, and through which part or all of the motor current passes. If all the current passes through the field coil, it is called a "series field coil." If only a small part of the current passes through the coil, it is called a "shunt field coil." Sometimes motors have both series and shunt field coils.

*348. What are the advantages and disadvantages of using permanent magnets?*

The advantage is that they do not require a continuous expenditure of energy while the motor is running. The disadvantages are that a permanent magnet cannot be made as strong as an electromagnet of the same size, hence the motor has less power; the strength of such a magnet would gradually become less, so that the speed of the motor would increase accordingly.

*349. Under what conditions are series motors used?*



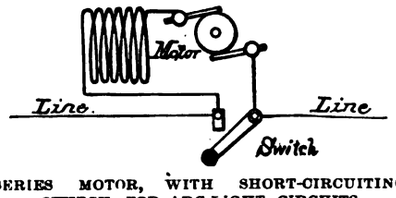
Small motors for use with primary batteries are commonly wound as series machines, likewise motors of any size intended for use on arc light circuits in which the current is of constant strength. Series motors are also used on constant potential circuits, as in railway work and for similar purposes where an attendant is always at hand to regulate or control the speed.

*350. What are the advantages and disadvantages of series motors?*

Series coils are somewhat cheaper to wind than shunt coils, because the wire is larger, costs less per pound and less labor is needed to wind comparatively few turns of large wire than to wind many turns of small wire. This is particularly true of small machines. Series motors are more easily started, especially under heavy loads. They maintain the speed more nearly constant than do shunt motors when on circuits in which the current is maintained at constant strength. When on constant potential circuits, such as used for incandescent lighting or for electric railways, the speed of a series motor will depend upon the load.

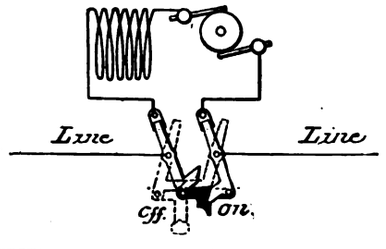
*351. How are series motors started on battery circuits?*

Small series motors operated by battery power are started by simply closing a



SERIES MOTOR, WITH SIMPLE CIRCUIT OPENING AND CLOSING SWITCH, FOR BATTERY CIRCUITS.

switch to complete the circuit, as indicated in the figure. The resistance of battery and motor is sufficient to prevent too great a rush of current at the start.

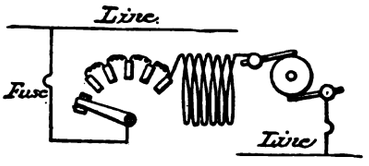


*352. How are series motors started on arc light circuits?*

Motors of arc light or "series" circuits are connected into the circuit in the same way as arc lamps. Some of them are pro-

SERIES MOTOR, WITH SHORT-CIRCUITING SWITCH, FOR ARC-LIGHT CIRCUITS.

vided with a simple single-pole switch that short-circuits the motor when not running, as shown in the figure. To start the motor, this switch is opened, or thrown to the "on" position, thereby sending the current through the motor instead of through the switch. No rheostat or resistance is needed, since the current



SERIES MOTOR, WITH DOUBLE POLE ISOLATING AND SHORT-CIRCUITING SWITCH, FOR ARC-LIGHT CIRCUITS.

through the motor cannot be greater at the start than when in regular running, this being kept constant by the dynamo. It is better to use a double-pole short-circuiting switch, in order to cut the motor entirely free from the circuit when not running; in fact, this is required by the insurance rules. Such motors require the use of high voltages, do not regulate satisfactorily and have gone almost entirely out of use.

*353. How are series motors started on constant voltage circuits?*

It is necessary to have some auxiliary resistance in series, as shown in the fig-

SERIES MOTOR, WITH SERIES STARTING RESISTANCE FOR CONSTANT POTENTIAL CIRCUITS.

ure, to prevent too great a rush of current at starting. The resistance of a 15 horsepower railway motor is only about 2 ohms. If this were connected to a 500-volt circuit while standing still and without any extra resistance, the current would be something like 250 amperes at the first rush, or more than 150 horsepower. By introducing more resistance into the circuit at first, the rush of current is reduced and the motor starts gradually. As the motor comes up to speed, the extra resistance is gradually cut out.

*354. How are series motors stopped?*

The operations in starting are simply reversed, care being taken to move the switches quickly in order to avoid excessive flashing.

*355. On what kind of circuits are shunt motors used?*

Shunt motors are used almost without exception on constant potential circuits. Some years ago the C & C Company made a motor for arc light circuits, having a combination of series and shunt coils, but this was about the only shunt motor used on such circuits.

*356. What are the advantages of shunt motors?*

They are very closely self-regulating, so that the speed remains nearly constant for any variation of load. They may therefore be left to care for themselves with only occasional inspection of bearings and brushes.

*357. What are the disadvantages of shunt motors?*

The speed cannot be varied through a very wide range without considerable loss. They do not start under a heavy load so easily as do series motors. In case the current should be cut off for any reason, and the motor should not be disconnected from the line before the current comes on again, the motor is more liable to be burnt out than would be the case with a series motor. The shunt motor requires more care in starting than does a series motor.

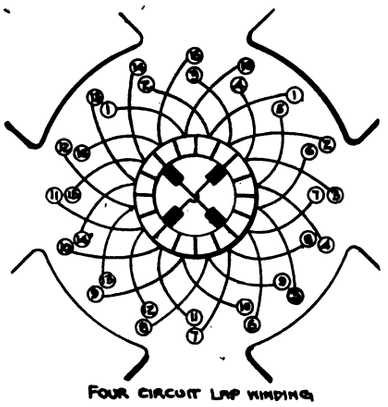
# Queries and Answers

In the Thomson recording wattmeters for direct currents, the terminals to connect to line are marked, one positive and the other negative, and the directions say to connect the + terminal with the + line, etc. Will you please explain why this is necessary? The meter is simply a shunt motor and the direction of rotation is the same, regardless of the direction of the current. J. W. L.

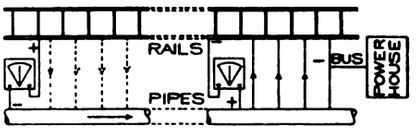
It is true that the Thomson meter is a shunt motor and should run in the same direction and record accurately connected up in either polarity. Although there is no iron or steel in the magnetic circuit of the motor, these materials do enter into the construction of the instrument and may retain a certain amount of residual magnetism, which on very light loads, where the meter is extremely sensitive, may affect the indications. The polarity marks indicate the way in which the meter was connected when calibrated and to obtain the highest accuracy should be followed when set up for service. For all practical purposes, however, it makes no difference which way the meter is connected.

Please give a sketch of how to connect up a double throw switch on a three-phase induction motor, so that the motor can be made to run in opposite directions. J. W.



The problem of connecting up a reversing switch to change the direction of rotation of a three-phase motor consists in so winding the circuits that the rotary field of the motor will travel in the reverse direction. If the three legs of the three-phase circuit are brought in the direction in which the phases follow each other, 1—2—3, it is obvious that their connection to the motor terminals must be changed into the order 3—2—1 to reverse the sequence of the phases and hence the direction of the rotary field. Considering the triangle 3 1 2 it is obvious that if these figures are read in clockwise rotation they read 1—2—3—1—2—3, etc. Now, if any two of them are interchanged, for instance, the 2 and the 3, the triangle becomes 2 1 3 and when it is read in the same direction

as before, it reads 1—3—2—1—3—2, etc., which is the same as 3—2—1—3—2—1, etc., i. e., the sequence of the phases has been exactly reversed. If any other two numbers of the first triangle are reversed, the third being left where it is, the result is the same. For instance, interchanging the 3 and the 1 gives the following arrangement 1 3 2 which also reads 3—2—1—3—2—1, etc. This interchanging is accomplished by means of a double pole triple throw switch, according to the sketch given herewith. A double pole switch is all that is necessary, since the connection in the left-hand leg is evidently the same in both the up and down positions of the switch, but it is customary to use a three-pole switch so that when the switch is opened the motor is entirely cut off from the supply circuit.



Will you please tell me how to connect the armature coils of the rectifier, the design of which was given in the American Electrician of June, 1899, when used as a direct current generator as per directions given in the Queries and Answers Department of the American Electrician for August. C. S.

The statement in answer to the query in August that the 16 coils could be connected either as a two or four circuit winding was an error. Sixteen coils can only be connected up as a four circuit lap winding. The connection of these coils to give 110 volts at 2400 r. p. m. is shown in the accompanying diagram. The small numbered circles represent the sides of the form wound coils, one side of coil No. 1, for example, occupying the bottom of the slot under coil No. 13, the other side of coil No. 1 occupying the top of another slot 90° away from the first over one side of coil No. 5. The opposite ends of each coil are connected to adjacent segments of the sixteen part commutator, each segment being connected to the end of one coil and the beginning of the next one to it. For instance, one segment connects with the end of coil 1 and the beginning of coil 2 and so on around the commutator. It will be noticed that each commutator segment is about midway between the two sides of the coils to which it is connected. If the terminals of each form wound coil are brought out together at the apex of the coil they will be convenient for connection in this way.

What do you think is the best way of overcoming the action of electrolysis from street railroads on water pipes? E. S. J.

The commonly accepted method in this country of reducing electrolysis is to carefully prevent any metallic contact between the rails and the pipes at points distant from the power house where the current tends to leave the rails and enter the pipes. Near the power house, where the current tends to leave the pipes and return to the rails, the pipes should be carefully connected with

this bus bar by heavy conductors bonded or soldered to them. No damage is done by the current entering the pipes, all metal being dissolved when the current leaves them. The direct low resistance path from the pipes to the negative bus reduces the tendency of the current to pass into the ground and thus back to the rails, while the isolation of the pipes from the rails at distant points reduces the amount of current that enters the pipes and must leave them again. Tests should be made with a low-reading voltmeter connected at different points between pipes and rails. Wherever the meter shows the rails positive to the pipes they should be kept apart from each other. Wherever the pipes are positive to the rails they should be bonded together.

What resistance generators and bells should be used for party lines wired on the multiple or bridging-bell system? Can No. 0 iron wire be used for the line and can 20 instruments be worked on one line of this kind? What size wire should be used for 10 instruments? J. B. O.

Use 1000-ohm ringers and 300-ohm generators, wound with No. 31 B. & S. gage. The generators must be very well made and have powerful magnetic fields. Twenty instruments are too many for good service on any one line. No. 10 B. & S. gage iron will not answer at all, unless the line is short. No. 10 B. & S. gage copper would be better, but unless instruments are exceptionally well made, trouble will be had in ringing. The same construction will answer for only 10 instruments.

Will the increase of temperature of a generator be the same whatever the normal temperature is in the room, i. e., will a machine rise with a given load 72° F. above the room when the room is at 60° F. and when it is at 107° F. respectively? W. D. T.

The rise of temperature of a machine with a given load above the atmospheric temperature will be practically the same, no matter what the latter is. If a machine loaded in a room at 60° F. rises to 132° F., it will, with the same load, in a room at 107° F., rise to about 180° F. At the higher initial temperatures the temperature rise will be a little greater owing to the fact that a given number of cubic feet of air blown through the machine will not represent quite so many lbs. of air since it is at higher temperatures expanded to a greater volume.

## MOTOR STARTERS WITH INTERLOCKING NO-VOLTAGE AND OVERLOAD RELEASE.

It is now almost universal in high-grade installations to protect direct-current motors with devices which will open the circuit in case of either the failure of the current supplied or the overloading of the motor. The former is most simply accomplished by means of the usual automatic motor starter fitted with a magnet which holds the rheostat arm in the closed circuit position. The overload protection may be obtained by the addition in the lines of an ordinary circuit breaker, but it is naturally preferable to combine this instrument in some way with the starting rheostat and underload device.

There are on the market several such combined protective devices. In one the releasing magnet which holds the rheostat arm in the short circuit position is wound with two coils, one, the usual potential coil in series with the shunt field of the motor, designed to let go when the voltage fails, and the other an overload coil in series with the armature of the motor, this coil neutralizing the magnetic effect set up by the shunt coil when the load rises above normal.

A more commonly used device is an overload coil, the armature of which when attracted short circuits the no-voltage coil and releases the rheostat arm. The objection to such devices compared with a starting box and an independent circuit breaker is the fact that the operator may start the motor under an overload, the automatic devices being inoperative while the operator has his hand upon the rheostat arm.

An instrument in which the overload protection is combined with the no voltage release in such a way as not to be subject to this disadvantage, is made by the Ward Leonard Electric Company, Bronxville, N. Y., and is shown in four sizes in Fig. 1. An examination of this figure and particularly of the upper right-hand rheostat represented therein will show that there are two arms fastened upon the same pivot, one the usual rheostat arm swinging over a number of contact buttons, and held in the short-circuit position by a no-voltage magnet, and the other a longer normally horizontal arm which is held in place by a trigger at its left-hand end, this trigger being within the range of the upward blow of the armature of an overload device similar to that used in circuit breakers. This arm is connected in circuit in series with the rheostat arm and when released by the overload trigger is forced open by the same spring that actuates the rheostat arm, and thereby protects the motor against the flow of excessive currents. The overload or circuit-breaker arm is not fitted with a handle by which it can be closed by hand, but must be restored by moving back the rheostat arm to the open-circuit position, this movement mechanically pushing back the circuit-breaker arm until it latches. If the operator in starting up the motor cuts out the resistance too rapidly the independent circuit breaker will instantly open the circuit, even while his hand is on the rheostat arm. In order to close the circuit breaker again the operator must first insert all of the resistance of the rheostat and then open the circuit by swinging the rheostat arm on to the open buttons, this movement carrying before it the circuit-breaker blade.. When the latter is latched the operator can again establish his circuit and gradually cut out the resistance. If an overload comes upon the circuit at any time with the motor running at full speed the circuit breaker acts and the operator, finding his motor stopped, knows, by an examination of the instrument, exactly what caused the stoppage, whether overload or undervoltage, which cannot be told by other types of instruments.

Another advantage of the same construction is as follows: In case the underload release of the rheostat should fail to operate when the line is opened and the motor should come to rest, leaving the rheostat in the short-circuit position, when the power returns to the circuit the overload arm would instantly open and protect the motor; whereas in the case of single-arm rheostats the motor would receive the entire voltage unprotected. Underload-release magnets are not absolutely reliable in this manner, as the arm must make good contact with the short-circuit jaws, fitting them tightly and requiring a very powerful spring to start it. The spring is also often insufficient to carry the arm, when released, clear over to the open-circuit position, especially if any buttons are burned or rough. In this case when the power returns the rheostat is burned out, as starting rheostats are not made with sufficient carrying capacity to stand the full-load current for more than a moment or two.

In order to overcome both of these difficulties the Ward Leonard Electric Company makes its rheostats of large carrying capacities with what is known as the "hammer-blow" feature. A view of an instrument with this attachment is shown in the lower right-hand corner of Fig. 1. From this it will be seen that the rheostat arm itself does not carry the armature of the no-voltage magnet but does carry a pin engaging another arm carrying this armature and also attached to the spring and handle. This hammer arm itself is freely pivoted and when released by the no-voltage magnet flies back quickly over an arc equal to that spanned by the slot in which the pin on the rheostat arm travels, strikes the latter a heavy blow which overcomes its friction of rest, disengages it from the jaws and carries it quickly to the open-circuit position.

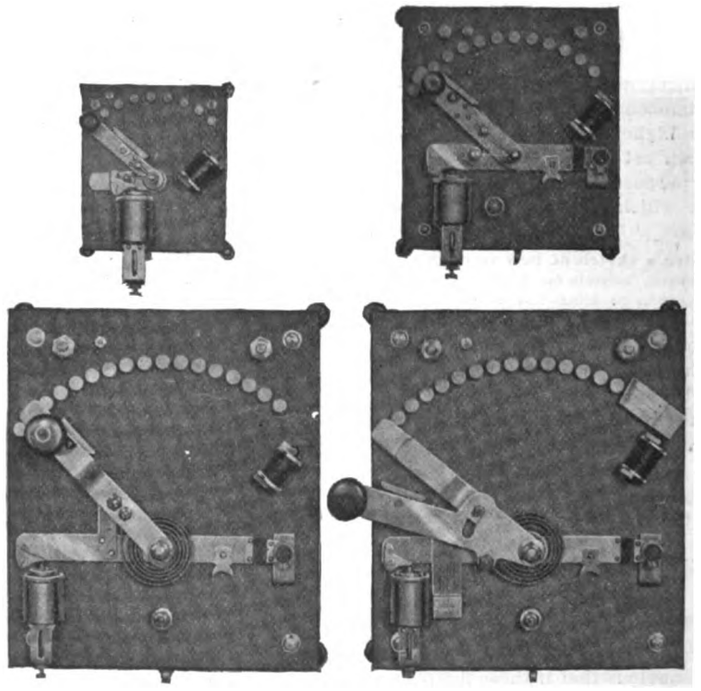

FIG. 1.—FOUR SIZES OF MOTOR STARTERS FITTED WITH INTERLOCKING NO-VOLTAGE AND OVERLOAD CIRCUIT OPENING DEVICES.

The contact of the overload or circuit-breaker arm is made in most sizes by means of a short copper rod, the end of which presses on a copper spring, this rod appearing in end elevation at the right-hand end of the arm. The copper piece on which it bears is flexible, being supported by a strip of phosphor bronze, and the copper rod can be adjusted in a clamp so as to vary the pressure between the contacts. This contact is reinforced by jaws in the sizes for large currents.

Fig. 1 shows four sizes of this rheostat. In the smallest, which is employed up to and including 3-h. p., the current capacity and contact surface are so slight that no hammer blow is needed on the

Digitized by Google

no-voltage release and no auxiliary break is needed on the circuit-breaker arm. In the intermediate size which is employed for 5, 7½ and 10-h. p. motors, the auxiliary break is employed on the circuit breaker, but the hammer blow is not needed on the no-voltage release. In the rheostat shown at the lower left-hand corner the current carrying capacity is still light, since it is designed for 500-volt circuits and 15, 20 and 25-h. p. motors. The auxiliary break is used on the cir-

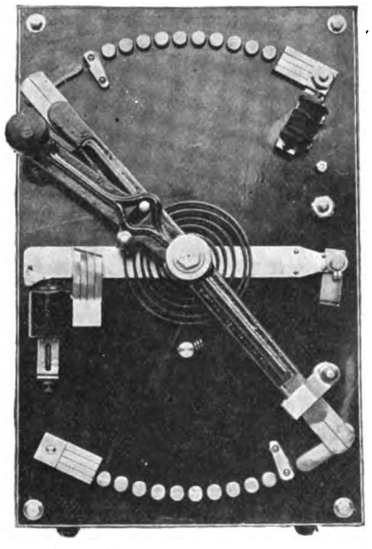

FIG. 2.—A 50-H. P. STARTER WITH ALL FEATURES.

cuit breaker, as the power of the circuit broken is considerable, but the hammer blow is not needed on the arm as low-resistance contact jaws are not used. The rheostat shown in the lower right-hand corner is that used for the same power motors on low-tension circuits, the final contact of the rheostat lever having jaws of the knife-blade type, insuring low resistance and no heating. The hammer blow is here necessary in order to start the blade.

The largest size of this style is 50-h. p., which is shown in Fig. 2. In this instrument the current, after passing through the solenoid and the knife-blade contact of the circuit breaker, divides from the center stud into two paths in multiple, i. e., the upper half and the lower half of the rheostat are two distinct resistances connected in multiple with each other. This doubles the carrying capacity of the instrument without increasing the size of the parts and gives balanced resistance to turning about the hub and smoother working. This instrument clearly shows the construction of the bumpers, which are not of rubber, as in other makes, but are coiled springs, giving a longer life. The rheostat arm is, in this instance, provided with a pair of friction clips at the lower right-hand corner for catching the arm and stopping it smoothly, there being also a coiled spring between the clips. The same view shows a modified construction of the first contact, which is elongated to give a larger surface for the heavy current required to start the motor against the friction of rest as well as to provide increased arcing surface on opening the circuit, since the greater the amount of metal the less will be the destructive action of a given arc. Another improvement of the same detail is the cutting away of the arcing edge in line with the contact buttons so that any burning of the rheostat arm will not roughen it where it travels over the various steps.

Another and still newer type of instrument, also made by the Ward Leonard Electric Company, is illustrated in Fig. 3, this being a motor controller as distinguished from a motor starter, and intended to carry the full load current on any step. The rheostat arm is not spring actuated and may be set on any button, another arm carrying the armature of the no-voltage release and the spring, this arm acting to give the rheostat arm a hammer blow and drive it to the open-circuit position from any button on which it may be placed. This instrument is made in two types, one designed to reduce to half speed a motor whose load requires the same torque at any and all speeds and wound, therefore, with a resistance of uniform carrying capacity throughout. The other is intended to reduce to half speed a motor driving a load of which the torque falls off as the speed goes down, such as a ventilating fan, the resistance of this rheostat being given a 2 to 1 taper in ampere capacity from the short-circuit to the open-circuit end.

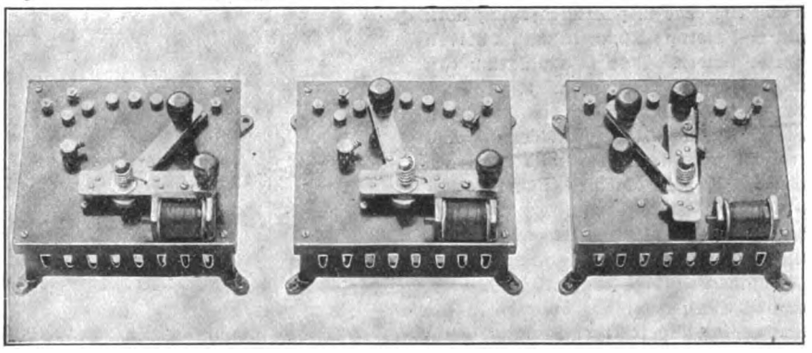

FIG. 3.—MOTOR CONTROLLERS WITH "HAMMER BLOW" NO-VOLTAGE RELEASE.

In the starters made by this company the resistance material is in the form of a high resistance strip, somewhat similar to German silver, which is about .002 of an inch thick and whose width is proportional to the ampere capacity desired, the object of this being to secure the maximum possible surface for a given cross section. This ribbon is reflexed back and forth edgewise and formed into steps, and proper terminals are attached at the junctions of different steps. This ribbon so formed is then attached to the back of the slate, the ribbon being held in position by pins, thin sheets of asbestos being employed to insure that no vibration can possibly bring the adjacent rows of ribbon into contact with each other.

The slate, with the switch part on the front and the ribbon on the back, is then fastened to the front of a casting, which is in the form of a shallow box with the front removed; i. e., the slate forms the front side of the box. There are two holes, into which screw plugs go, at the top edge of the box, and through these holes the box is then entirely filled with the best grade of white sand. Sand has exceedingly valuable properties for use in connection with starters; its first cost is comparatively low, its specific capacity and conductivity for heat is quite high, and its mobility insures continual contact with the ribbon at a very great number of points. Its use for this purpose is similar to the familiar sand bath used in laboratories in connection with flasks and beakers, in which case the sand serves the purpose of storing a large amount of heat and of conducting it rapidly to the lower surface of the beakers at a very large number of points. These same properties apply in the case of a starting rheostat in which the ribbon is suddenly heated by a large current and it becomes important to rapidly conduct away from the resistance a large amount of heat energy and store it up in a comparatively small volume, from which it will slowly radiate during the interval of rest, before the motor is started again.

Sand has also the good feature that it can be very quickly applied by merely pouring it into the box through a funnel, and similarly it can be very readily removed in case it becomes desirable to inspect the inside of the box, and after inspection the sand can be readily replaced by any unskilled person. The joint between the chambered casting and the slate is made by means of putty, which prevents the sand from leaking out.

The dimensions of the starting rheostat made after this style are extremely small compared with those of any other type. The 50-h. p. starter shown in Fig. 2 has a slate which is only 16 inches by 25 inches, and the depth of the rheostat is only about 3 or 4 inches. A starting rheostat for 50-h. p. made by any of the former methods would be probably ten times the size of this one in volume.

## THE CHAPMAN VOLTAGE REGULATOR.

In spite of the perfection of the speed regulation of modern prime movers, as well as the voltage regulation of modern dynamos, the extreme requirements of high efficiency incandescent lamps necessitate a close watch of the voltage on the part of station attendants and frequent manipulation of the rheostat. This is particularly the case in plants carrying both a light and motor load, or in plants driven by water power. This manipulation can be done just as satisfactorily, or even more so, by automatic means, reducing considerably the attention necessary and allowing the station attendants to give a much greater part of their time to other duties.

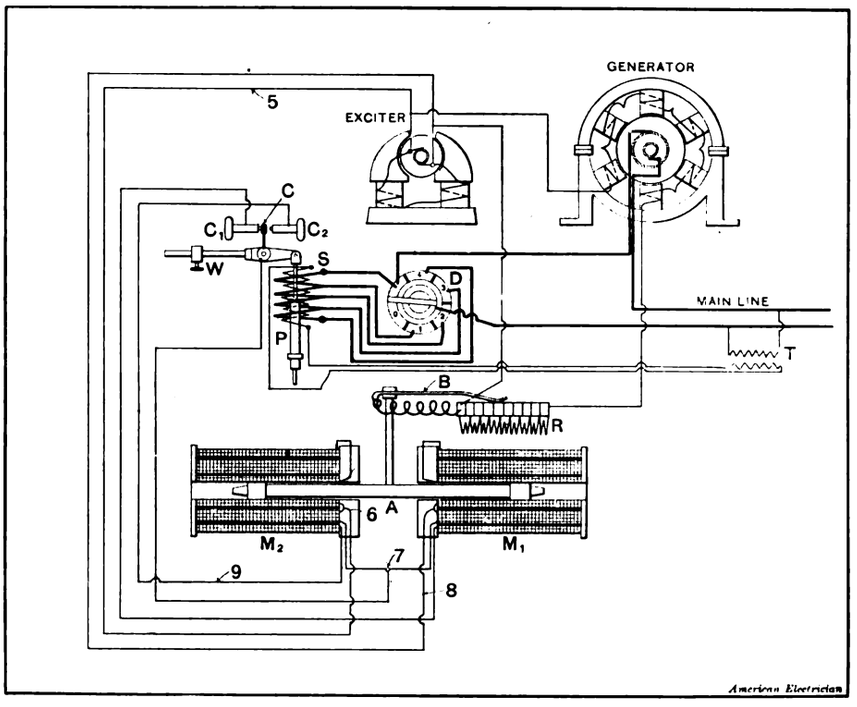

FIG. 1.—THE CIRCUITS OF THE CHAPMAN REGULATOR.

The most generally used means of manipulating the rheostat automatically is the Chapman voltage regulator. A view of one of these machines appears in the accompanying illustration, Fig. 2, a complete diagram of the parts and circuits of an instrument regulating an alternator being shown in Fig. 1.

The instrument in principle embodies a solenoid connected across the mains and thereby excited in proportion to the voltage of the machine, this solenoid operating a delicately poised movable contact which plays between two stops. The solenoid and its plunger have no other work to do than to operate the light contacts, serving as a relay to control a more powerful mechanism which does the work of moving the rheostat arm. The instrument is thus sensitive to a very slight differences of voltage.

In Fig. 1 the generator to be controlled is shown in the upper right hand corner of the diagram with the exciter slightly to the left of it. The main generator circuit passes out to the right and across it is connected a transformer T. The secondary of this transformer supplies the inside or high wound coil of the solenoid S. The magnetism set up by this solenoid tends to lift the plunger, P, against the force of gravity and thereby to operate the contact, C, between the two back contacts $C_1$ and $C_2$. These three contacts are connected into the circuits of a pair of powerful magnets, $M_1$ and $M_2$, which in turn act upon the opposite ends of a soft iron armature, A. This armature is attached at its middle point to a post carrying the rheostat slider or brush, B, operating over the segments of the field rheostat, R, and cutting out more or less of its resistance according to the position which the brush occupies. The voltage at which the relay shall lift up its plunger is adjusted by means of the sliding counterweight, W.

The coils of the main magnet are supplied under the control of the contacts from the exciter and are ingeniously wound so that the making and breaking of the circuits gives least inductive action and negligible sparking at the contacts. This is accomplished by winding the magnets differentially and connecting the contacts so as to neutralize one magnetic field when a contact is made. Each magnet, $M_1$ and $M_2$, is wound with two coils, one formed, as shown, of the outer and inner layers, and the other of the intermediate layers. The different coils are connected up as follows: From the upper brush of the exciter the wire, 5, leads to the terminal, 6, of the magnet, $M_2$, where it forks, one circuit passing through the middle coil to the common junction, 7, and thence through the middle coil of magnet $M_1$ to the wire, 8, and back to the lower brush of the exciter. This circuit is constantly excited.

From point 6 another circuit leads through the inner and outer layers of $M_2$ in series with each other through the wire, 9, to the contact, $C_2$, which, when contact, C, is in the right-hand position, gives another path from the point, 6, to the point, 7. The coils in this path are wound in the opposite direction from that in the other path and the current divided through the two neutralizes the magnetism of $M_2$. At the same time the increased current due to the reduced resistance of the two coils in parallel with each other increases the magnetism of $M_1$ and draws the armature, A, to the right. A similar connection of the coils

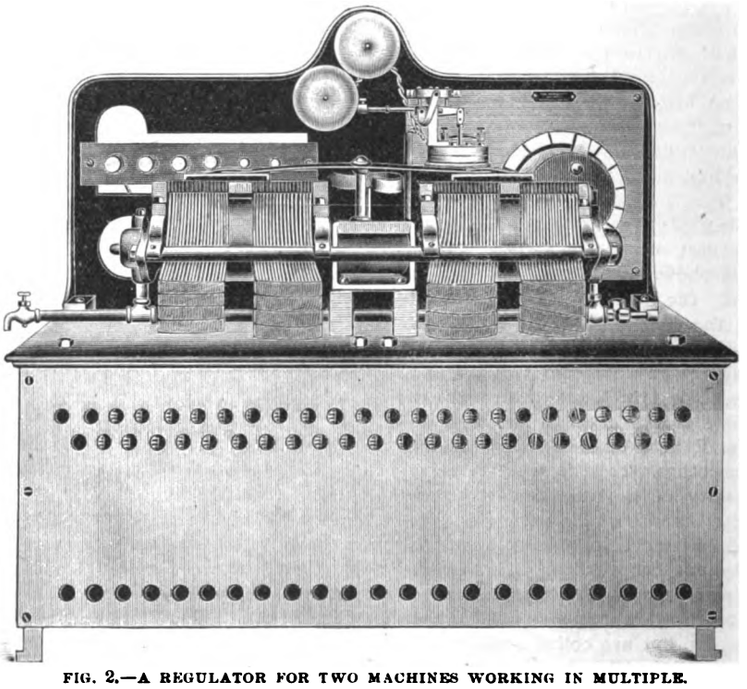

FIG. 2.—A REGULATOR FOR TWO MACHINES WORKING IN MULTIPLE.

Digitized by Google

of $M_1$ and the contact, $C_1$, gives a reverse movement without retractal springs or weights.

The movement is rendered sluggish by making the spools on which the magnets, $M_1$ and M , are wound, into oil dash pots, the ends of the armature, A, serving as pistons. The outer ends of the dash pot are connected through a small pipe and a petcock, the adjustment of which allows the speed of the armature in either direction to be controlled with precision.

A description of the operation of the parts may make their purpose more clear. When the voltage, for any reason, rises above that for which the instrument is set, the transformer, T, magnetizes the inner solenoid, S, and draws up the plunger, P, making a contact between C and $C_1$ as shown. This throws the two windings (one right-handed and one left-handed) of magnet $M_1$ in parallel with each other, neutralizing the magnetism which draws the plunger to the right, and allowing M to pull it to the left. This moves B to the left, cutting in more resistance in the field rheostat, R, in series with the separately excited field of the main generator.

The solenoid, S, affecting the delicately poised relay, is in this instrument compound wound, the outer coil being connected in series with the main line. The compounding may be adjusted at any time while the machine is running by means of the rotary dial switch, D, the segments of the switch, 01234, being tapped to different turns of the series winding of S. By rotating the switch arm the series current may be sent through any required number of turns, changing the amount by which the machine will over-compound. Alternators of any size may be compounded in this manner without commutators for rectifying the current in the series fields.

The instrument shown in Fig. 2 has two independent rheostats for running two machines in parallel, the sliders or brushes of the two rheostats being mechanically connected to one main armature. Each of these rheostats has two separate commutators and brushes, so that a considerable change of resistance is effected with a limited movement and with segments of reasonable width.

The apparatus is made by the Belknap Motor Company, Portland, Me., whose representative for the Middle Atlantic and Southern States is Mr. A. W. Koenig, with offices in New York City.

## ANOTHER SERIES ALTERNATING ARC SYSTEM.

In the endeavor to adapt one kind of current to all the services of central stations so that but one type of generator need be used, the alternating-current motor and the alternating-current constant-potential arc lamp have been brought to a satisfactory stage of perfection. More recently the problem of running series arc-light circuits from constant-potential alternating-current mains has been attacked, and the General Electric Company has developed a system of constant-current transformers which was described in the issue of the American Electrician of last July. These transformers, as the reader may remember, take the power at constant potential from the bus bars or lines into their primaries and deliver constant current from their secondaries regardless of the resistance of the secondary circuit within the capacity of the transformer, the voltage delivered to the secondary circuit being adjusted for its varying resistance by automatically varying the position of the coils on the transformer core.

Another and simpler means of accomplishing the same purpose has been developed by the Manhattan General Construction Company of Newark, N. J. In this system the series circuit of lamps is connected across the constant potential mains without any special transformer, but in series with a regulating reactance coil. This coil automatically increases its choking effect when the lamps are cut out and the resistance of the line is thereby lowered, and vice-versa, and in this manner maintains constant current in spite of the constant-potential supply. The regulating reactance coil consists of a single coil swung at one end of a counterweighted arm, so that by moving vertically it will enclose more or less of one leg of an upright U-shaped laminated core of an open magnetic circuit. Normally when no current is flowing the coil is held by the counterweight outside of and above the core. When the circuit is completed through the lamps the magnetic attraction of the coil for the core causes it to be drawn down, and as the current increases the coil is drawn to a lower position. The self induction or choking effect of the coil increases as it lowers around the core, thereby regulating automatically and in a very simple way the strength of the current to a value determined by the counterweight.

This regulator may be furnished with self induction sufficient to provide for the extinguishment of all the lamps in the circuit, or if the circuit is a street lighting one and but a few lamps are likely to be out at any one time, the regulator may be smaller and sufficient only to give a choking effect the equivalent of 10, 15, 25 or any other percentage of the total voltage. In this case the cost of the regulator is greatly reduced, as not only is it smaller, but the strain upon its insulation and the necessary dielectric strength therefore are correspondingly reduced. For this reason the regulating reactance coil is cheaper to build than the automatic constant current transformer, since the latter—even if provided for regulation with only a small percentage of the lamps extinguished—must have a core and coils capable of transforming the total power and insulated for the whole of the high secondary voltage.

## THE HISTORY AND PRESENT STATUS OF THE ARNOLD ELECTRIC POWER STATION COMPANY.

When some five years ago the advantages of direct-coupled dynamos and engines, as compared with belted arrangements, were fully appreciated, one factor that hindered their more rapid adoption was the diminished flexibility incurred by the new system.

In the transformation of energy from the coal pile to the electrical circuits it has become approved practice to connect the steam pipes of all the boilers and engines together to one main or header so that any engine can get steam from any boiler, and to connect all the generator leads and feeders to one set of bus bars so that any load can get current from any dyuamo. In plants built in the past a similar trunk system for the mutual interchange of mechanical power was provided by the countershaft, to which any engine could deliver power and from which any generator could obtain it. Ordinary direct-coupled units failed to provide this cross connection of the power-transforming apparatus at the mechanical stage.

Mr. Bion J. Arnold set himself to the task of devising a means of overcoming this deficiency in direct-coupled plants and developed what is known as the "Arnold System," in which a number of engines and dynamos are set up in line with each other with appropriate interconnecting shafts and clutches, by means of which the different machines can be run together or separately, just as they can when connected by belts to a countershaft. A clear comprehension of the general principles of this system can be obtained by a study of the description of a plant of this kind appearing on another page of this paper under the title, "The Isolated Plant of a Wholesale Grocer's Establishment."

The Arnold Electric Power Station Company was organized in 1896 to make and sell the parts peculiar to the "Arnold System" of power station construction, and acting in this capacity it has supplied a number of plants with magnetic clutches, shafts, quills, box stands and couplings. Through natural development this company has gradually broadened the scope of its work until it is now in position to make propositions for furnishing and erecting in place entire electrical installations.

The entire power plant and building of the Imperial Electric Light, Heat & Power Company, at St. Louis, Mo., was constructed by the Arnold Company. This plant is a large central station using 500-volt generators working in parallel with a storage battery auxiliary. By dividing this battery into two parts a distribution system was devised which allowed the use of 220-volt incandescent lamps, arc lamps, and power motors off the same mains, a decided departure from central station practice in this country. This system has been adopted for another large

Digitized by Google

central station since the erection of the Imperial plant.

The Arnold Company was also given the contract for the complete light, heat and power plant erected in connection with the new railroad shops of the Chicago Great Western Railroad at Oelwein, Iowa. This contract comprised not only the heating and lighting of the shop buildings, covering many acres, from a central plant, but also the application of a large number of motors for various uses. This has been the first plant to adopt the Arnold magnetic clutch for line shaft work, though these clutches have been used for some time in connection with the three-way couplings which are a part of the Arnold system of power station construction.

The Arnold Company has extended its field of operations into the complete equipment of the power generating and distributing systems of electric railways and notably of long distance roads. The most elaborate work of this kind undertaken by the company is that for the Chicago & Milwaukee Railway, a line 27 miles long, recently completed along the shore of Lake Michigan, north of Evanston.

Mr. Arnold, while acting as consulting engineer of this road, realized four years ago, and probably as early as any one else, the advantages for such lines of polyphase distribution and the rotary converter, especially when combined with storage batteries at the sub-stations to render uniform the load on the generating, distributing and converting system, a combination which has since been adopted for several large systems both in this country and abroad. In spite of its novelty and the engineering problems to be solved in connection with it, and in the face of considerable opposition, Mr. Arnold advocated this plan strongly for the road above mentioned and finally, in order to justify his position, the Arnold Company took the rather unique contract for the completion of the power station, sub-stations and lines laid out in this way and guaranteed the entire system to work with a certain specified efficiency.

This contract included the engine, direct-current and alternating-current generators, switchboards, transformers, rotary converters, economizer, pumps, mechanical draft, condensers, piping, cooling table and reservoir, power-house building, battery room, car barn, offices, two sub-stations, overhead equipment and transmission line erected complete, ready for operation. The contract for this equipment would have been notable in itself, but the economy clause gives to it an added interest.

The policy adopted by the Arnold Electric Power Station Company of working out its own solution of an engineering problem, of submitting plans and specifications, with its proposition, together with an economy guarantee covering the entire installation, takes this company at once out of the ordinary class of contracting companies and places it in a position peculiar to itself. Another unique feature of the Arnold Company's methods is that it is in no way connected with any manufacturing company, which leaves it free to purchase machinery and apparatus of any make upon the open market.

The advent into general electrical contracting work of a company prepared with an organization capable of handling the largest contracts and willing to guarantee the operation and economy of a completed plant or installation is a development which promises to bring about new methods in building extensive electric properties.

## THE WESTINGHOUSE GAS ENGINE.

So much has been written of late concerning the adaptability of gas engines in general, and this one in particular, to the driving of electrical generators, that nothing need be said here on this subject or the general principles of gas engine operation, the article below being largely a description of the details of construction of the Westinghouse engine.

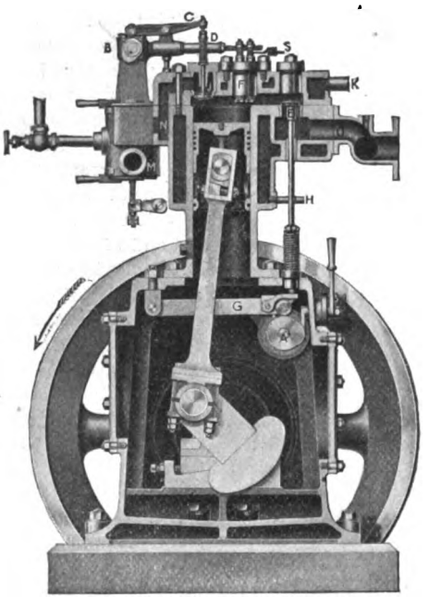

FIG. 1—SECTION THROUGH ENGINE.

Like practically all other types of commercial gas engines, the Westinghouse is single acting and operated upon the Beau de Rochas, or, as it is more commonly known, the Otto cycle.

Unlike other gas engines, however, the Westinghouse does not govern its speed on reduced loads by skipping impulses, the reduction of power in this engine being obtained by throttling the incoming air and gas and thereby reducing their quantity during each cycle without materially changing their relative proportion. The governor can thus assume any intermediate position and on a steady load remain in this position instead of being compelled to travel constantly back and forth over its entire range in order to hit or miss a stroke. This constant travelling from limit to limit is necessary on hit-or-miss governors and necessitates a constantly recurring variation of the speed from the upper to the lower governing limit and vice versa, no matter how heavy the fly wheel may be made.

The engine is vertical, with either two or three cylinders, in all sizes as yet constructed, thus getting either one impulse per revolution, or one during every two-thirds of a revolution. The cylinders are mounted on top of an enclosed crank case resembling in appearance and functions that of a Westinghouse steam engine. A good idea of the arrangement of the parts can be obtained by reference to the vertical cross section, Fig. 1.

Their operation is as follows: The entering gas and air come in through openings, one of which is shown at M, to and through the mixing valve, the purpose of which will be described below, and pass through the port, N, to the upper side of the poppet valve, J. This is depressed by a cam shown on the cam shaft, B, acting on a lever, C, once during each two revolutions of the engine in order to admit fresh gases above the piston. The latter is of the trunk type, enclosing its own crosshead pin, which has the usual wedge arrangement for adjusting the phosphor-bronze boxes. An interesting detail of this part of the engine is the hole through the piston wall opposite the screw of this wedge and the hole near the lower end of the cylinder, with a plug which can be removed, and through which an ordinary socket wrench can be inserted when the piston is in the proper or lowermost position, to adjust the crosshead pin boxes.

The exhaust valve is also of the poppet type and is shown at E. It is lifted against a spring by means of the lever, G, a roller on which bears on a cam on the shaft, A. This also operates once during every two operations of the engine in proper time to release the burned gases. The cycle of operation is as follows:

The piston being in its uppermost position and the cylinder cleared of the last charge, the valve, J, is opened and the piston descends, drawing into the cylinder an explosive mixture of gas and air of a quantity determined by the governor. The valve, J, then closes and the piston returns upward, compressing the charge into the clearance space in the head of the cylinder. The mixture is then ignited and the piston descends again, pushed down by the high pressure caused by the burned gases. The valve, E, is then opened, and the piston rises, driving out the exhaust gases, and leaving the cylinder in condition for a repetition of the same events.

The ignitor is electrical in character and is shown at F, and in greater detail in Fig. 2. It consists of a removable bonnet containing two independent sets of contacts, only one of which is in use at one time. These are brought together by a cam on the upper shaft B, operating through the guide, D, and are suddenly

Digitized by Google

released and forced apart by springs at the proper time for the explosion, that is, when the piston is at the head of the cylinder with a compressed charge of air and gas in the clearance space. The failure of either pair of contacts to work can be instantly remedied by transferring the wire from one to the other of the binding posts and thus bringing into service the other pair. The location of all parts of the ignitor in the removable bonnet makes their removal and renewal peculiarly easy. A similar construction is adopted for the admission valve and even the exhaust valve is placed under the bonnet shown at S, through which it can be readily lifted out for cleaning or regrinding.

The engine is water-jacketed to prevent overheating, the cooling water entering at H, passing upward around the cylinder and through the cylinder head and out at K.

The arrangement of the governor and its parts is shown more clearly in Fig. 3. The speed sensitive device is of the ordinary centrifugal fly ball type, moving upwardly or downwardly a mixing valve above it. The nuts holding two vertical coil springs to either side of the valve stem allow the speed to be changed or adjusted even while the engine is in operation. The mixing valve carries ports for both gas and air. The valve seats of either or both of these may be manipulated by hand at any time even when the engine is running so as to regulate the relative opening of the two and thereby the ratio of gas to air in the entering mixture. There will be seen just above and below the valve chamber two handles with index fingers operating over scales. One of these affects the air port and the other the gas port through the valve. By varying the relative openings at any time while the load is constant and watching the position of the governor, the mixture giving lowest consumption of fuel can be found by actual trial instead of by guessing as in other engines.

The automatic starting of engines too large to be started off by hand is ingeniously provided for by means of an air compressor and a storage tank and an arrangement to use one of the cylinders as a compressed air motor for a few turns in starting. The tank when shipped is charged to 160 lbs. pressure and is recharged after starting by a belt, which is then thrown off, or it can be recharged by hand. To start the engine the admission valve of one cylinder is rendered inoperative and the exhaust valve of the same cylinder is thrown by means of a handle appearing at the right-hand side of Fig. 1 on to a separate cam which causes the valve to open during every up stroke instead of every other up stroke of the piston.

The compressed air supply is then turned into this cylinder through a small auxiliary starting valve which turns the air on during every down stroke of this one cylinder, and the engine is turned over by hand gear until the air is admitted and forces the piston down. The other cylinder or cylinders then take hold, operated by gas, as usual, and bring the engine up to speed, when the one used as an air motor may be restored to its proper function. Three or four revolutions with the air pressure are generally sufficient. The largest engine so far constructed, viz., one of 650-h. p., is regularly started by one attendant in this manner.

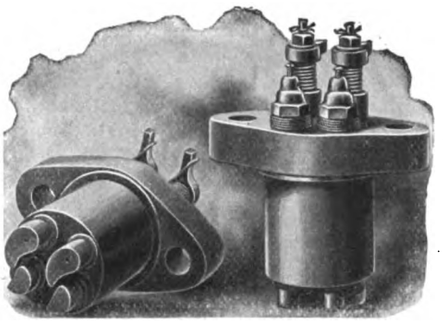

FIG. 2.—TWO VIEWS OF THE IGNITOR.

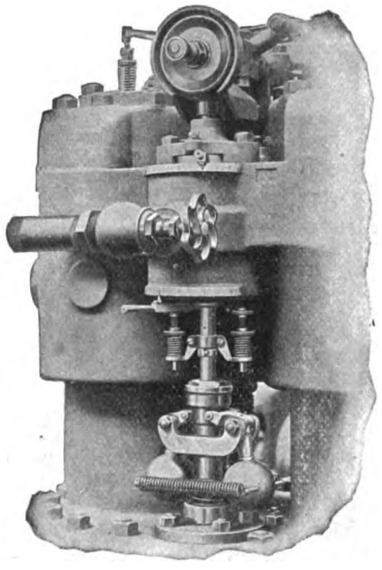

FIG. 3.—THE GOVERNOR OF A TWO-CYLINDER ENGINE.

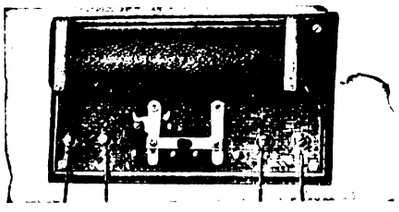

FIG. 4.—THE BATTERY SPARK COIL.

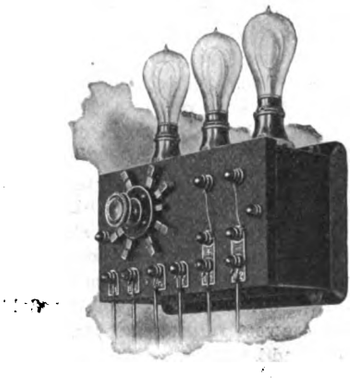

FIG. 5.—THE DYNAMO SPARKING OUTFIT.

The current for the ignitors may be furnished as usual by a battery through a sparking coil, the battery being connected up with a reversing switch so that the direction of the current through the igniting apparatus may be reversed at will. The coil and switch are shown in Fig. 4. This reversal is used to prevent the passage of the spark from eating away one terminal and depositing its material on the other, the reversal interchanging the parts and returning the material to the terminal first eaten away. The switch is fitted with a locking device such that whenever the battery is cut out, as it should be when the engine is shut down, it can only be cut in again in the reverse direction.

When a direct current lighting or power circuit is convenient, it may be tapped for supplying the ignitors, the switching device for this arrangement being shown in Fig. 5. This is fitted with lamps to serve as a resistance in series with the contact and with the sparking coil, which is, in this case, located within the box. The switch is so arranged that either the battery or the dynamo current may be cut in at will and so that each time a change is made the direction of the igniting current is reversed from that on the previous run.

These engines can be worked with gasolene by means of a special "gasifier" made also by the Westinghouse Machine Company. This consists simply of a cylinder into which the gasolene is sprayed and through which air is drawn to the gas inlet of the engine. In this cylinder the fine gasolene spray vaporizes and is carried along by the stream of air, making a gas of suitable richness. The change from the liquid to the gaseous state absorbs considerable heat, which is supplied by means of a water jacket around the gasifying cylinder, which water jacket is supplied with warm water from the water cooling jacket of the engine cylinder.

The gas consumption of this engine is given by the makers as follows:

Natural gas, 10 to 12 cu. ft. per brake horse power hour.

Ordinary city gas, 15 to 17 cu. ft. per brake horse power hour.

Commercial 74° gasolene 1/9 to 1/8 gal. per brake horse power hour.

The probable consumption of fuel for producer gas, as estimated from experiments carried on at the works in Pittsburgh, will be about 1¼ lbs. of anthracite coal per brake horse power hour in small and about 1 lb. in large engines.

As noted above, the largest engine built as yet is of 650-h. p., but the company states that "Neither in its construction or working have we encountered anything which would lead us to think that the limit of size has been anywhere nearly reached."

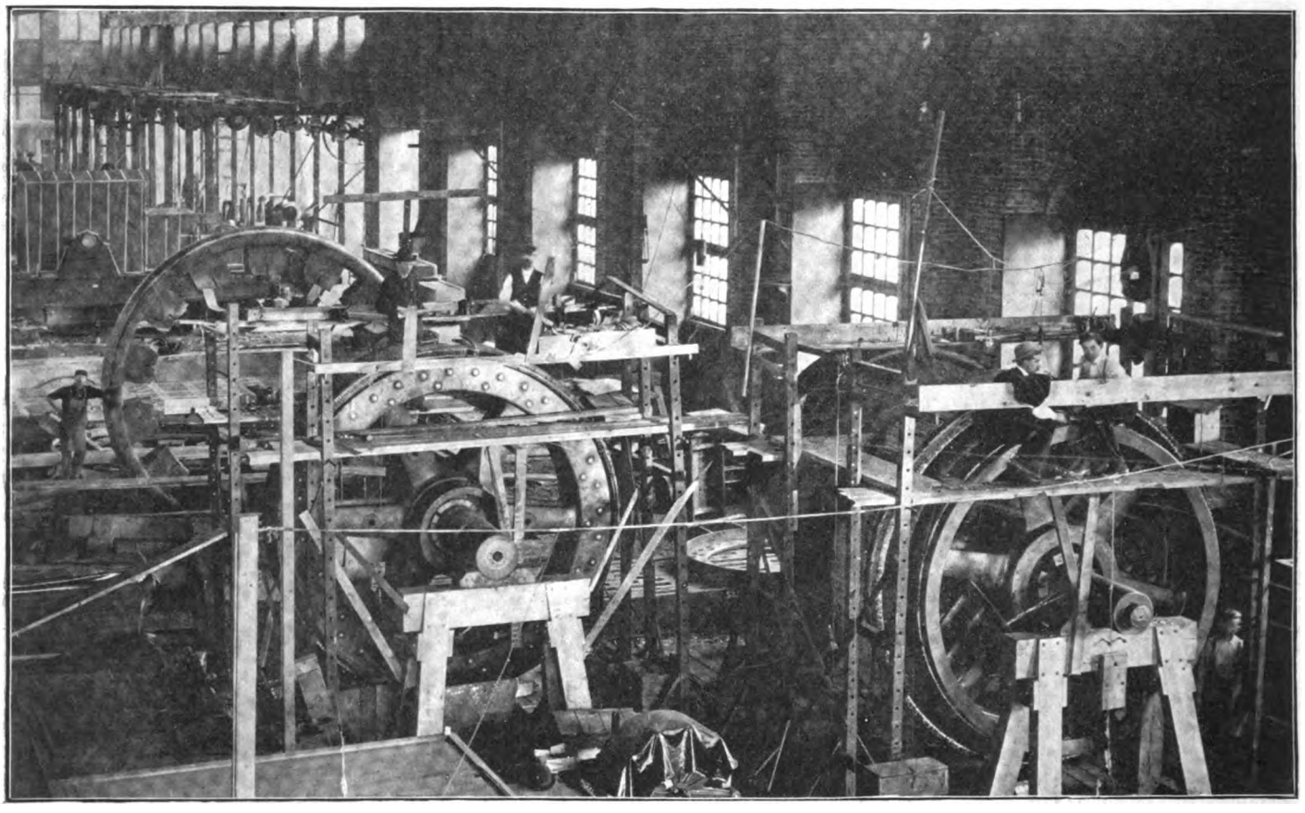
## THE NEW LINES OF MANUFACTURE OF THE SIEMENS & HALSKE ELECTRIC COMPANY.

The fact that the Electric Vehicle Company has bought the stock of the Siemens & Halske Electric Company of America and will at the works of the latter company manufacture electrical machinery for its vehicles—for which other allied companies, viz., the Electric Storage Battery Company and the Columbia and Electric Vehicle Company, will manufacture other parts—has led to a general belief that the Siemens & Halske Company would cease operations as a manufacturer of dynamos and other electrical machinery for the general trade.

So far from this being the case, the Siemens & Halske Company, to which new life has been brought by its present powerful financial connections, is branching out into a line of electrical manufacture almost as general as that of the two largest concerns in this line in this country and on a scale excelled only by these two.



The agreement with the German parent company of the same name, granting the American company the rights to all its patents in this country, still holds, and the American company has engaged a large staff of engineers and draughtsmen and is vigorously pushing work on a great number of new designs. The works in the West Side of Chicago, formerly the Grant Locomotive Works, have assumed a new air of activity, the force having been increased within thirty days by some 250 men, including a night shift. Another large building, not previously occupied by the company, will probably be taken and filled with the automobile work. In this line the company is already at work on 2,000 motors for the recently heralded order for 4200 automobiles. The older portions of the works have been fitted out with much new apparatus, including a heavy testing floor, a new japanning room, with ovens specially designed for clean work, and a cupola for light castings, etc.

In the way of generators the company will continue to build to order the outside armature type, either slotted and with a separate commutator in large sizes, or smooth body with self-contained commutator in smaller sizes. The company will, however, continue to manufacture and to recommend in preference its inside armature machines, for which it now has many recent improvements. These are built with barrel windings, the end connections being supported by an end plate suitably ribbed to give ventilating passages through the coils. The company is now building of this type three 1,500-kw. machines for the North Western Elevated Railway of Chicago, five new 500-kw. machines for the Imperial Company of St. Louis, two 800 and fourteen 400-kw. machines and others of smaller sizes for other orders. In the way of smaller dynamos there are being developed lines of closed-coil arc machines, revolving field alternators, street railway motors, rotary converters and boosters.

A new line manufactured by this company is meters. Mr. Thos. Duncan, formerly with the Fort Wayne Electric Corporation, having joined the Siemens & Halske Company and brought with him the patent rights to the Duncan meter, which is now being manufactured in a new form called the improved Duncan meter.

Another new line is that of enclosed arcs, and still another is that of transformers, which are now being made in small sizes of the shell type, with sandwiched coils, giving close regulation.

The personnel of the company has been greatly changed by its recent reorganization: Mr. I. L. Rice, formerly President of the Electric Storage Battery Company, is now President of the Siemens & Halske Company; Mr. C. S. Knight, formerly of the Fort Wayne Electric Corporation, is Vice President and General Manager; assisted by Mr. A. Churchward, formerly of the Excelsior Electric Company, and more recently with the Fort Wayne Electric Corporation, who is chief engineer; Mr. Thomas Duncan is directly in charge of the meter department; Mr. F. L. Sessions is chief of the draughting department, and the staff includes also Mr. Thos. Drohan and other experienced designers, a large number of whom came with Mr. Knight from the Fort Wayne Company. Mr. C. E. Wilson is general Eastern agent for the Siemens & Halske Company, with headquarters at Philadelphia; Mr. F. A. Wunder is manager of the New York office; Mr. E. T. Pardee represents the company at Boston, Messrs. T. J. Ryan and T. C. Harnish at Cincinnati and W. R. Mason at St. Louis.

# New Apparatus and Appliances

## THE BELDEN ENCLOSED ARC LAMP.

The reduction of the complication of automatic machinery to the lowest possible limits is especially imperative where such machinery is scattered, not under the immediate attention of experienced attendants and exposed to abuse and unfavorable climatic conditions. For this reason the development of enclosed arc lamps is not a simple problem and new and improved forms of lamps continue to appear on the market. The latest is one made by the Belden-Larwill Electric & Manufacturing Company of Ft. Wayne, Indiana, various views of the interior parts of which are shown in Figs. 1, 2 and 3.

The frame of the lamp consists of two tubes of cold drawn steel such as are used in bicycle frames, brazed to two circular steel stampings and supporting at their upper ends a hollow casting or sheave wheel housing, making a very rigid structure. The upper carbon holder is suspended within one of the tubes by a chain passing over a sheave wheel carrying a counterweight in the other tube. The sheave wheel is fixed to a hardened steel shaft that is fitted with ball bearings equal in every respect to those used in high grade bicycles.

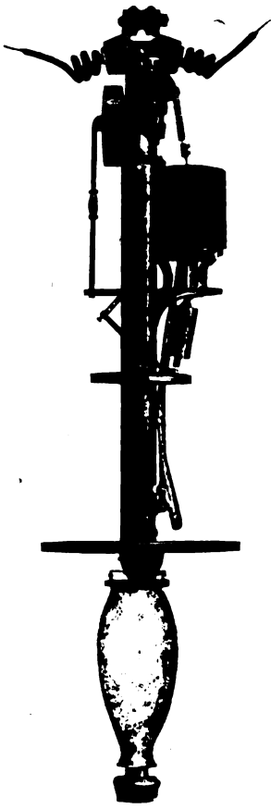

FIG. 1.—EDGE VIEW OF LAMP MECHANISM SHOWING TOGGLE.

The actuating magnet and mechanism, shown in Fig. 2, are self-contained and are connected to the lamp frame with a single screw. The iron core is drawn vertically into the solenoid or magnet, and being connected to a peculiar arrangement of lever and toggle movement, shown in the cut, the motion and force given to the clutch rod are uniform throughout its travel. The clutch rod carries at its upper end a U-shaped dog or clutch, shown in Fig. 2, tilted back from the projection, E, on which it normally rests. This clutch engages the flange of a wheel fixed to the projecting end of the sheave-wheel shaft already described, imparting to it a rotary motion which separates the carbons and strikes the arc. When the magnet core lowers, due to the burning away of the carbons, the clutch swings around with the wheel to such an angle that it releases itself without striking a trip post of any kind, thereby allowing the carbon to feed down.

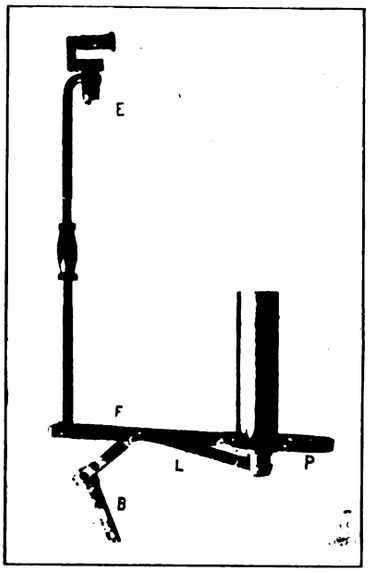

FIG. 2.—THE MOVING PARTS OF THE MAGNET AND CLUTCH MECHANISM.

The peculiar toggle joint arrangement of the parts, L, B and F, in Fig. 2, is to provide increased power when the plunger is well up within the solenoid and subject to a smaller pull per ampere of current in the coil. This gives a greatly increased range of motion on normal current and a positive separation of the carbons at the arc to three times the normal distance, a feature which eliminates the hissing and simmering of a short arc, common with other arc lamps in which a slight wear has made it impossible for the carbons to properly separate to the normal distance when the current is turned on.

The working parts are attached to each other by means of hardened steel triangular pins similar to those used in scales, which eliminates all likelihood of friction and sticking due to the parts getting out of alignment or becoming corroded or gummed by oil.

The greatest disadvantage occasioned by the introduction of enclosed arc lamps is that due to the high temperature which the parts near the arc attain and the consequent difficulty of handling them for retrimming when the lamp has been recently burning. This difficulty is eliminated from this lamp, as it may be retrimmed in any one of the following ways: 1st, by unscrewing the knurled cap at the bottom of the lamp; this being a part of the lower carbon holder, removes with it the burned out lower carbon, allowing the upper carbon to pass out through the same opening without the removal of the inner globe. New carbons may then be inserted into their holders in the reverse order. 2d, should the upper carbon be broken short in its holder, the stub may be removed by pressing the small latch at the back of the inner globe bracket, whereby it may be drawn down and turned to one side, giving free access to the upper carbon holder. 3d, by the same operation of removing the lower carbon holder the inner globe is released and can be removed by simply lifting it out. When cleaned and replaced the lamp may be trimmed as before.

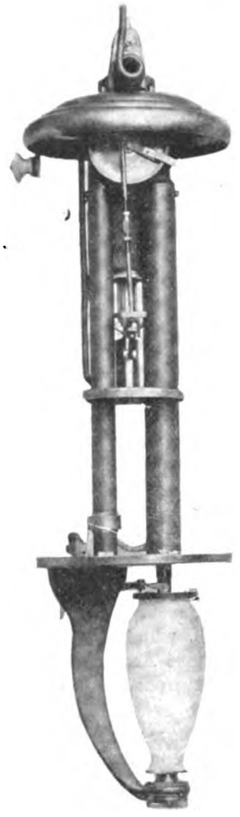

FIG. 3.—SIDE VIEW OF THE LAMP SHOWING CLUTCH.

The other advantages of the lamp may be summarized as follows: The springs usually employed in the mechanism of arc lamps have been eliminated, thereby securing a permanent adjustment at all times regardless of changes of temperature and length of time. There are no sliding contacts to corrode or cause trouble. The current is carried to the upper carbon by means of a flexible asbestos-

Digitized by Google

covered cable. The peculiar construction of the dash pot allows the carbons to come together instantly in case the arc breaks or the current is shut off. No metal is used inside the inner globe, which is fitted with a carbon gas cap and bottom. This prevents the deposition of metallic vapors on the globe and consequent discoloration.

The lamp is the design of Mr. E. H. Belden, who has made a special study of the experiences of arc lamp users and the troubles found in this line of work, the new model being designed to, so far as possible, overcome the objections of older types.

### A GENERATOR FOR USE WITH GAS ENGINES.

The usual gas or gasoline engine of the type employing the Otto cycle gives necessarily a rather unsteady motion, due to the fact that there is per cylinder only one impelling stroke in two revolutions, and before each active stroke there is a heavy compression or power-absorbing stroke. In addition to this, the governor, if, as usual, of the hit-or-miss type, must move from one extreme to the other of its range every time the engine misses and again take a charge, which it is constantly doing at all times except when loaded up to its maximum possible capacity.

In order to prevent this pumping of the speed of the engine from making itself evident in the candle power of incandescent lamps it is customary to belt the engine to the generator with as much flexibility as possible and give to the latter a considerable fly-wheel effect in order to steady its speed of rotation. A countershaft is sometimes used in order to give two lengths of belt between the engine and dynamo, and even greater flexibility can be obtained by means of leather link or other belts which will run extremely slack.

Fig. 4 shows a generator made by the E. G. Bernard Company, Troy, New York, specially adapted for this work. So far as its magnetic and electrical features are concerned, the machine is similar to others of the same make, but structurally it differs in having a web fly wheel added. This fly wheel is placed on the commutator end of the machine, giving, with the pulley at the other end, a well-balanced rotating structure symmetrically arranged with regard to the two journals. In this respect the machine differs from many others designed for the same purpose which are fitted with a fly wheel integral with the driving pulley.

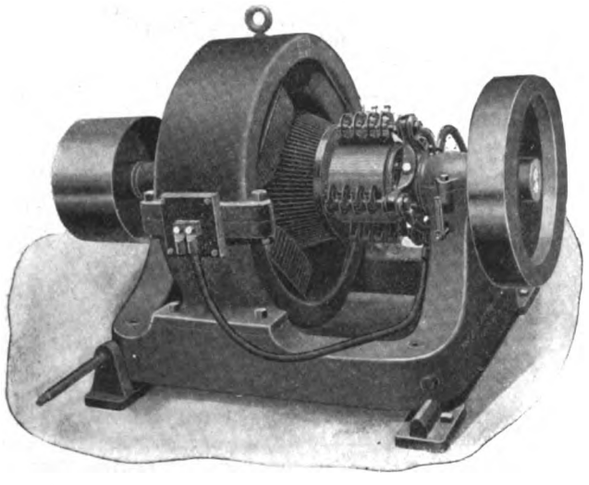

FIG. 4.—A FLY-WHEEL GENERATOR FOR USE WITH GAS ENGINES.

### A NEW MAKE OF RAILWAY GENERATORS.

The Bullock Electric Manufacturing Company, Cincinnati, Ohio, has commenced the construction of a new line of machines larger than those formerly built, viz., direct-coupled railway generators. These possess, as a rule, the features of the smaller machines made by the same house and have some new ones, among the more important of which may be mentioned a mechanism for oscillating the brush holders in a direction parallel with the shaft. The movement is a very slow one and results in constantly shifting the track of the brushes across the commutator face and preventing the cutting or grooving of the latter. The action is the same as that secured by the end play of an armature in a belted generator or that produced by the electro-magnetic device used at the ends of the shafts of rotary converters. The new machines have cast steel circular yokes with soft steel laminated poles. Each armature coil is a continuous bar of copper from tail to tail of the commutator segments. A machine already built of the largest size designed, viz., 800-kw., is shown in Fig. 5. These generators are fully described in Bulletin No. 0434.

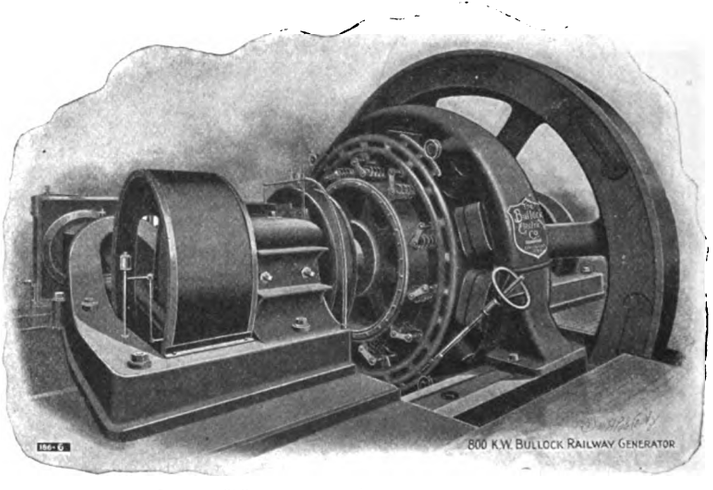

FIG. 5.—AN 800-K.W. BULLOCK RAILWAY GENERATOR.

### A PORTABLE PHOTOMETER.

The word photometer conveys to the mind of the average engineer the idea of a dark room containing a long and heavy bench on which are mounted scales, traveling carriages, lamps, mirrors, etc., a combination which at first thought would appear to be impossible to reduce to a portable form.

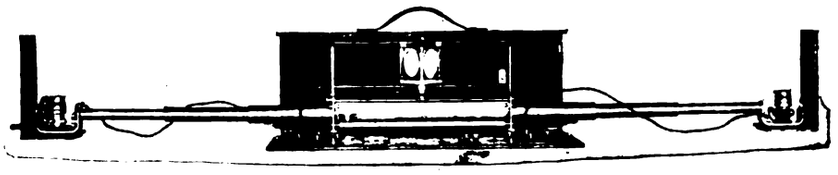

FIG. 6.—A SMALL AND PORTABLE PHOTOMETER.

Although portable photometers have been made containing the greater part of this apparatus, notably an oil burner, which is necessarily clumsy and inconvenient in such an instrument, the application of what is known as the "same circuit" method allows the simplification of the photometer to such a degree that it may be reduced almost to the dimensions and weight of a Weston measuring instrument. This method of photometric measurement is described on another page of this issue so that it is unnecessary to discuss it here. The portable photometer in which it is employed is shown in Fig. 6.

Structurally it consists of a box, the front side of which opens downwardly on the table or bench on which it is set, and holds the switches and circuit binding posts. The two ends of the box pull out with the lamp bases attached to them and are maintained at the proper distance and in alignment for photometric measurements by means of telescopic aluminum tubes. When the photometer is closed these tubes collapse into the cylinder on which is wound the resistance for adjusting the instrument to lamps of

Digitized by Google

various rated voltages. This resistance is connected in series with the working standard and in contact with it is an adjustable slider working over a scale properly graduated to the voltage of the lamp under test; that is to say, if the lamp to be tested is rated at 112 volts the slider should be set opposite the 112-volt mark on the scale and will thereby insert sufficient resistance to bring down the pressure on the working standard from 112 volts to its rated voltage. As pointed out in the article above referred to, the determination of the candle power may be determined at this or any other voltage, constant or fluctuating, reasonably near it.

Three working standards are used, one for lamps between 50 and 60 volts, another for those between 100 and 120, and another for lamps above 200 volts, and 3 scales for the resistance slider are in place for these three standards.

The disc is of the grease spot type, mounted on a simple form of carriage fitted with cords by which it can be manipulated from the operator's position. The usual inclined mirrors to either side of the disc for reflecting the image of the grease spot forward are also tilted upward and backward so that the image is thrown upward and the operator need not stoop to the level of the instrument.

The receptacle of the test lamp is mounted for rotation and whirled by a bevel gear and a small hand crank to give mean horizontal candle power. Current is led to the lamp through silver collecting rings and silver tipped brushes, this metal being used since its oxide is not an insulator.

The working standard is a lamp of low efficiency, and consequently slow deterioration, burned or aged to make its candle power more constant, and is made with a coiled filament giving maximum distortion of the candle power distribution in a horizontal plane. The bulb is fitted with an arrow to indicate the proper direction in which it gives its standard candle power and this arrow can be changed from time to time when the working standard is recalibrated by comparison with a primary standard.

The whole apparatus is most ingeniously designed and worked down to minimum dimensions. Its weight complete with case is only 6½ pounds. It is made by the Bryan-Marsh Company, New York City, and was particularly gotten up for the educational work carried on by the lamp salesmen of this company among lamp users, although it is of practical value to a much wider class of electrical engineers.

---

### AN IMPROVED CABLE HEAD AND DISTRIBUTING BOX.

In the running of telephone or telegraph lines wholly as overload separate wires insulated from each other and the ground by glass insulators and air, or wholly in the interior of lead-covered cables insulated by paper, paraffine or rubber, but little difficulty is found in eliminating disturbing currents and cross talk. But when the lines are partly in cables and partly open, as most lines nowadays must be, the point of junction is that of greatest weakness.

The interior of the cable must be hermetically protected from the weather and every conductor must be brought out from it in some way to the exposed open lines. Every conductor must further be protected by means of a lightning arrester to prevent lightning discharges from entering the cable, and fuses must be used to peep out high-pressure currents. The apparatus must be located in exposed positions, generally at pole tops, where dirt and moisture come in and corrode contacts, cause leakage between the parts, and consequently cross talk between the lines.

Fig. 7 shows a terminal designed to reduce these difficulties, and made by the Moon Manufacturing Company, Chicago.

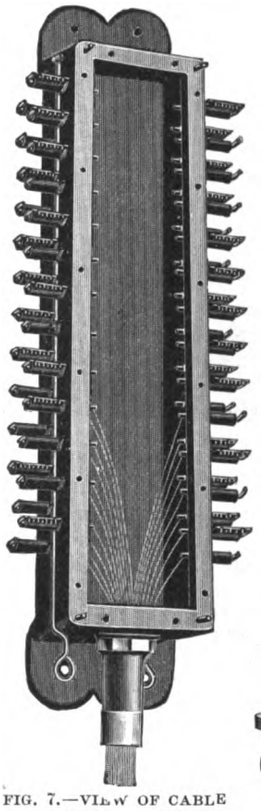

FIG. 7.—VIEW OF CABLE TERMINAL REMOVED FROM CASING AND WITH CAST-IRON COVER OF TERMINAL BOX REMOVED.

The cable head proper consists of a cast-iron box, within which the conductors of the cable are fanned out to their terminals, the box being then closed hermetically by a cast-iron front screwed on over a rubber gasket. Each terminal is forced to a tight fit in the side of the box, all being near a heavy vertical copper wire or rod, shown in the illustration, which serves as a lightning arrester. The terminals have slots or grooves, into which a channeled or corrugated fuse support may be slipped. The illustration shows some of the terminals with the fuse support in place and some without. The fuse is laced into the channels or partitions in the fuse support, so that although the distance in a straight line between its ends is but 1 in. the length of the fuse is 3½ ins.

The cast-iron cable head, with its fuses and lightning protective arrangements complete, is then enclosed in an outer casing of galvanized iron, the sides of which catch under lips on the back, so that the casing may be opened by sliding it vertically upward, this arrangement being far preferable to the usual doors on hinges which are likely to be left unfastened and fly open, allowing the rain to enter at any time. The sliding joint makes the casing quite moisture proof.

---

### IMPROVEMENTS IN INDUCTION METER DESIGN.

The most prevalent faults in alternating current meters of the induction type are the entrance of dust, the weight and consequent friction of the moving parts, the pounding of the jewel or other support by vibrations set up by the alternating currents, the weakening of the permanent magnets by the influence of the alternating field near them and the loss of energy in the shunt circut.

In the meter shown in Fig. 8, which

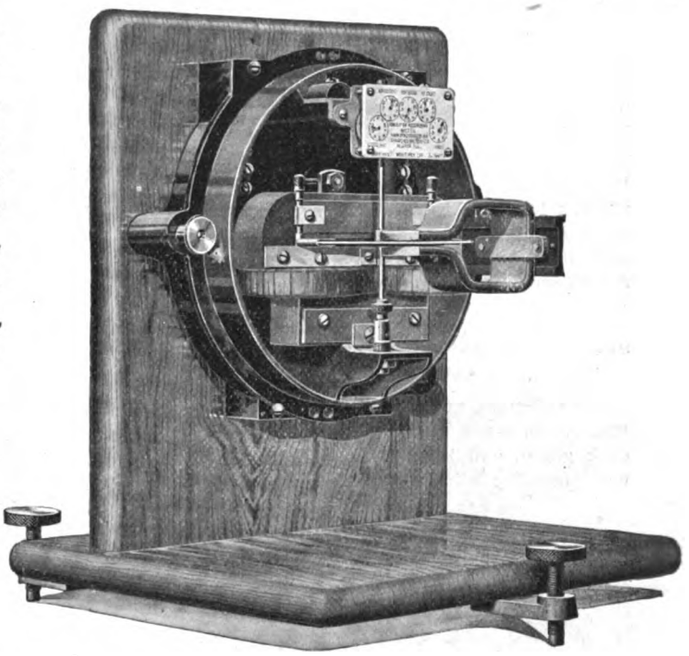

FIG. 8.—THE SCHEEFFER WATTMETER, WITH CASE REMOVED AND MOUNTED ON LEVELING CABLE FOR TESTING.

was designed by M. G. A. Scheeffer, and is manufactured by the Diamond Meter Company, Peoria, Ill., these faults have been eliminated or rendered negligibly small in the following ways:

The meter shell has been made cylindrical in form, as the illustration shows, the case of sheet metal being forced on over a rubber band or gasket, which surrounds a projecting flange from the frame of the meter, this flange tapering slightly so that the case when forced on makes a tight fit. The connecting or binding posts of the meter are covered with fibre bushings forced tightly into place through holes in the casting, making a tight fit

Digitized by Google

at these points. The holes into which the connecting wires are inserted are not drilled through the binding posts. Thus the meter is practically hermetically sealed when the case is on, and is dust, moisture and bug proof.

Both the driving and braking elements of the moving part consist of one single light aluminum disc, greatly reducing the weight on the jewel. This disc runs between the coils carrying the alternating currents at the back of the meter and between the poles of the retarding magnet in the front of the meter, thus serving both functions.

It is claimed that the loss in the shunt circuit amounts to only ½ watt on 125 cycles and ¾ watt on 60 cycles, the small amount of power so used not only being an economical feature, but reducing the pounding of the jewel and the stray field which weakens the permanent magnet.

The series coils consist of a few turns of wire without any iron core, and therefore with small inductive drop, and give the meter a straight line characteristic, which insures accuracy even with excessive overloads, as there is no iron to be over-saturated. The drop through the meter at full load is claimed to be only about 1/10 of a volt.

Embracing the disc at each side of the center is a small shield, these shields tending to give the disc an initial torque in opposite directions regardless of the load. This torque may be accurately balanced between the two or by slightly twisting either one or both the meter may be given a tendency to turn in the right direction sufficient to balance the friction and allow a very slight percentage of the rated current to start the mechanism.

### MIRROR REFLECTORS FOR INCANDESCENT CLUSTERS.

The reflectors, one of which is shown in Fig. 9, are made of heavy tin, japanned dark green, and lined with glass plated with metallic silver, the plating being protected by a coating rendering it impervious to moisture or other injurious surroundings. The glass gives a surface which does not tarnish and is readily cleaned. The reflecting surface is made up of a large number of sector-shaped facets, any one of which is easily replaceable when broken by bending the bronzed lead edge which holds them in place.

Reflectors of this style are made by the American Reflector & Lighting Company, Chicago.

FIG. 9.—A REFLECTING MIRROR ON AN INCANDESCENT CLUSTER.

### TELEPHONE PROTECTIVE DEVICES.

For the protection of delicate instruments, such as telephones, connected to overhead lines, against both lightning and powerful currents, a device combining a fine fuse with a narrow air gap to ground has become standard. The fuse is generally mounted on a strip of mica or pasteboard, with small extensions of tinfoil in contact with the fuse, and glued to the ends of the strip in such a way that they will come in contact with clips or jaws into which the whole may be readily inserted.

The protection against lightning takes the form of two carbon plates, one connected to the line and the other to ground, pressed together by springs and separated by a thin sheet of mica or paper, preferably perforated, the separation maintaining open circuit between line and ground across which the lightning can readily jump.

The accompanying illustration, Fig. 10, shows one form of double-pole combination fusible cutout and carbon lightning arrester on a porcelain base intended for independent instrument protection on metallic circuits and made by the Harvard Electric Company, Chicago, Ill.

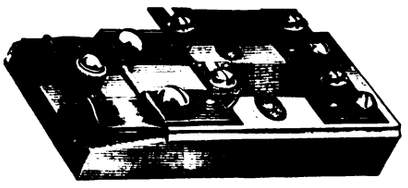

FIG. 10.—A DOUBLE-POLE PORCELAIN CUTOUT AND LIGHTNING ARRESTER FOR TELEPHONE LINES.

This device is also made up in a single-pole form for instruments used on grounded or common-return circuits, as well as in banks for use at the switchboard of the exchange.

### A NON-MAGNETIZABLE WATCH.

For those whose watches are affected by the stray fields of dynamos and motors near which they work, the watch represented in Fig. 11 has been especially designed. The hair spring and balance are not made of steel, palladium being used in its place. An incidental advantage of this metal is the fact that it will not rust. The balance is also compensated for extreme temperature changes. The watch is made by A. C. Becken, Chicago.

FIG. 11.—THE WORKS OF A WATCH WITHOUT A STEEL HAIR SPRING.

### NEW TELEPHONE APPARATUS.

A new form of granular transmitter, in which some objections to older forms have been overcome, is illustrated by the cross section shown in Fig. 12. From this section it will be seen that the transmitter proper or cartridge is assembled and screwed together entirely separate from the outer casing and may be removed and cleaned by any inexperienced person without disturbing the adjustment of its parts. This construction is accomplished by fitting the diaphragm and carbon parts in an inner metal casing independent of the outer metallic shell, a threaded ring fastening the diaphragm in place whether the cap holding the parts is screwed down upon it or not. The solidity of construction obtained in this way obviates the necessity of any adjustment of the instrument after it leaves the factory, even if the shell receives considerable knocks or is indeed forced to a certain extent out of shape.

The transmitter is made by the Tucker Manufacturing Company, York, Pa., which has equipped its factory to manufacture every part that goes into the construction of telephones and is prepared to furnish complete exchange instruments. The company's apparatus includes some other improved parts, among them novel forms of transmitter arms and receiver hooks.

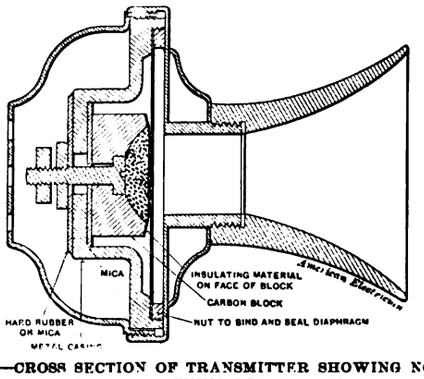

FIG. 12.—CROSS SECTION OF TRANSMITTER SHOWING NOVEL MEANS OF FASTENING DIAPHRAGM.

### AN AMMETER OR VOLTMETER SWITCH.

It is customary when using many independent machines or bus bars or bringing pack pilot wires from several points of distribution to arrange a switch in such a way that one voltmeter can be transferred to any pair of wires in order that it may measure the pressure from any one of several sources. The Weston ammeter of

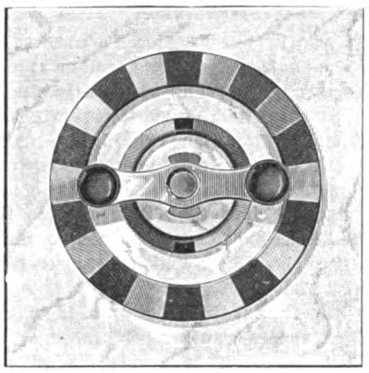

FIG. 13.—A SWITCH FOR THROWING A VOLTMETER OR AMMETER TO ANY ONE OF SEVERAL CIRCUITS.

the switchboard type is nothing more nor less than an extremely low-pressure voltmeter connected by shunt cords to the terminals of a low-resistance shunt carrying the current to be measured. The instrument proper simply measures the fall of potential in this shunt, which is of course proportional to the current flowing. On this account a switch exactly like that used for voltmeters could be connected to an ammeter and various shunts located in the different circuits in such a way that the one instrument would measure the current in any one of them according to the position of the handle of the switch. Owing, however, to the very low voltage of the instrument circuit the switch when so used must have highly perfect contacts, as any imperfection in this respect would utterly ruin its indications.

The switch shown in Fig. 13 was designed by Mr. J. W. Mabbs, engineer of the Chicago Board of Trade, for this service. As may be seen, it consists of a pair of semi-circular contacts forming an inner ring and connected to the instrument terminals, and a number of insulated segments forming an outer ring, there being twice as many of these segments as there are circuits to be connected. The rotating arm is double pole, the two halves being insulated from each other although the illustration does not indicate this. By moving it from segment to segment, the instrument may be connected with any one of the desired circuits. Forcible contact is made with the inside cylindrical faces of the outer segments, giving a path of very low resistance. The insulating divisions between the outer segments are of ample width to prevent cross connection when the contact passes from one to another.

When used with a voltmeter the switch allows the transformation of the one instrument to a ground detector from either bus. When used with an ammeter it allows the one instrument to be thrown on to any circuit, giving a means of measuring the output over any feeder at will, which measurement is at times extremely desirable, but is not, as a rule, considered enough so to warrant the expense of an instrument in every circuit. The switch should also prove useful as a synchronizing switch in alternating-current plants.

### A FEED WATER FILTER AND OIL SEPARATOR.

All condensing steam plants returning the condensed exhaust from the hot well to the boilers as feed water, or non-condensing plants using open feed water heaters in which the feed water is heated by the intermixture of exhaust steam, require some device for eliminating the cylinder oil from the exhaust or feed water to prevent the gradual accumula-

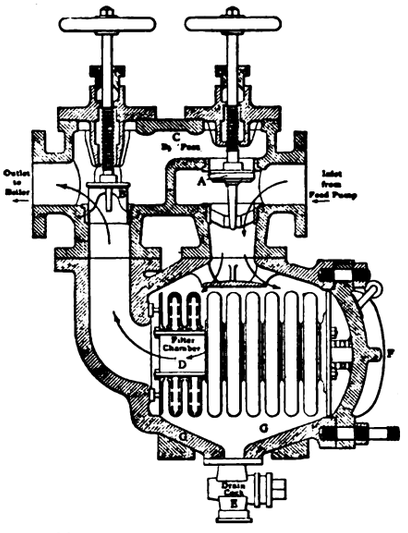

FIG. 14.—A SECTIONAL DIAGRAM OF OIL SEPARATOR, SHOWING BYPASS AND REVERSING VALVES.

tion in the boiler of the oil constantly pumped into the cylinders.

In marine engine practice, where the same water is necessarily used over and over again, it is customary to use filters of a type in which the water is strained through some fabric which retains the oil but allows the water to pass. A filter of this kind now on the market for land as well as marine practice is shown in Fig. 15, the details of its construction being shown by the vertical section Fig. 14.

The fabric used is Turkish toweling in the shape of a large bag, which is drawn over a skeleton made of circular bronze sections of open lattice work shown separately in the left-hand side of Fig. 15. The bag is drawn down between the circular sections by strings and the whole is then inserted in the filter in the position shown in the diagram. This manifolding or fluting of the toweling gives a large area for the water to pass through, from 250 to 1000 times that of the feed pipe, and consequently a slow velocity through it, in minimum space occupied.

The water enters, as the arrows indicate, through valve A, passing through the filtering material and out through valve, B, to the boiler. The oil or other matter separated accumulates on the outer side of the filtering material and gradually increases the resistance to the flow, this resistance being indicated by the difference between the readings of the two pressure gages shown in Fig. 15. When this difference reaches two or three pounds the filter may be cleaned by reversing the flow of water or by renewing the skeleton and bag through the removable head with the aid of the handle shown attached to the skeleton in Fig. 15. To provide for this removal the valve, A, is fitted with a face on each side of its disc which may be closed on either an upper or lower seat. With the disc down and the valve, B, closed, the feed water is by-passed around the filter, which may then be opened for removal of the clogged toweling. The same ingenious arrangement of valves allows for the reversal of the flow. This is done by closing A and opening the drain cock at the lower part of the filter and valve B. The water then flows outwardly through the filtering material, carrying the oil with it into the drain pipe.

These filters are made by the Ross Valve Company, Troy, N. Y., for use on some of the largest transatlantic steamers, the latest being the Oceanic of the White Star Line, and also for many steam power stations on land.

### THE GAS ENGINE OF THE COLUMBUS MACHINE COMPANY.

Among the particular features of the engine illustrated in Fig. 16 is the method of operating the valves and governing

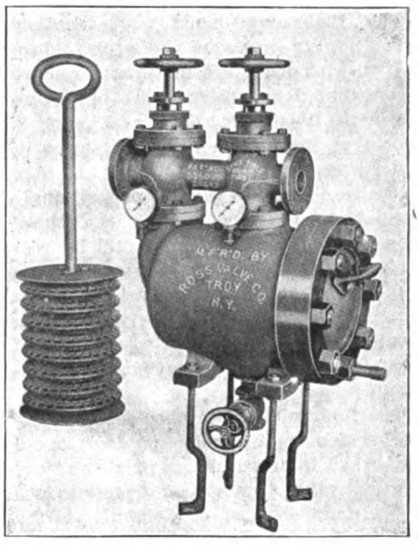

FIG. 15.—A VIEW OF OIL SEPARATOR, SHOWING LATTICE WORK SKELETON REMOVED.

mechanism, the power for which is communicated from the main shaft by means of spiral gears operating a horizontal shaft extending along the side of the engine. At the end of this side shaft near

Digitized by Google

the head of the cylinder of the engine is a clutch cam which is given an intermittent motion by means of the governing mechanism. This cam operates the fuel and exhaust valves, which are located in removable cases beneath the rear end of the cylinder, by means of arms which are made adjustable to take up any wear of the cam. The valves are of the poppet type and the cams are backed off so that

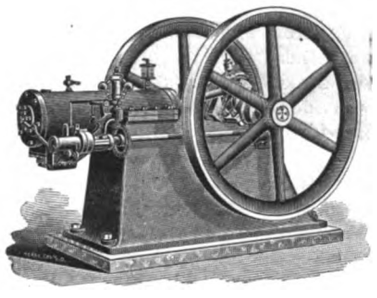

FIG. 16.—A GAS ENGINE CAPABLE OF MAKING HALF IDLE CYCLES.

when the valves are seated it is accomplished without sudden shock to the valve, thus reducing wear and breakage.

It is a fact well understood by those familiar with gas engines that in the single cylinder hit-and-miss-type of engine, which is the most common of all, when the engine cuts out its fuel it is necessary to complete the cycle revolutions at least before the engine can again take an impulse. Where close regulation is necessary and where an engine is working close to its rated capacity, the speed may have become accelerated sufficiently for the governor to act and cut out, yet in a single revolution the speed may drop sufficiently to allow another impulse, were it possible to obtain one. Not being able to do so, the engine must make another revolution to complete the cycle before the working parts are in time to receive a new impulse. On the type of engine herewith illustrated the clutch cam is such that the governor may act upon it, causing it, after having cut out, to take up its load again at the end of any single revolution, thus preventing the speed from dropping more than would be possible while the engine was making one single revolution of the fly wheels. This is a feature which is entirely new in a single cylinder, hit-and-miss engine and it contributes to the closest possible regulation.

The fuel valve is another special feature of this engine and is so constructed that when taking a charge of air and gas the air valve has a lead over the gas valve, thus operating economically in the consumption of gas. This lead of the air valve over the gas valve can be varied by simple adjustment.

The cylinder of this engine is constructed with a solid explosion head, dispensing with any packed joints, and is provided with a very liberal water space around the valves and cylinder.

The Columbus Machine Company, Columbus, Ohio, is building these engines at the present time up as high as 60 h. p., but expects to add still larger sizes during the coming season.

### A NEW FORM OF EXHAUST HEAD.

One of the important features of a non-condensing steam plant is the exhaust steam pipe head. Its purpose is the same as that of a steam separator, viz., to extract the water from the steam, and thereby prevent the constant spraying of roofs and walls with consequent deterioration and expensive repairs. In the form of exhaust head built by the B. F. Sturtevant Company, Boston, Mass., and illustrated in Fig. 17, the principle of centrifugal force is utilized to secure a high degree of separation.

Dry exhaust steam weighs only .038 lb. per cubic foot, while water of the same

FIG. 17.—AN EXHAUST HEAD CONTAINING A CENTRIFUGAL SEPARATOR.

temperature weighs 59.36 lbs. per cubic ft. It is therefore true that particles of water in the exhaust will be thrown outward with 59.36/.038 or 1562 times the force exerted upon steam occupying the same volume. In the Sturtevant exhaust head the steam passes up the interior pipes, is discharged tangentially close to the shell, and is thereby given a vigorous whirling motion. The entrained water—likewise the oil—flies outward, strikes the cool side and trickles down to the outlet at the bottom. The steam, now dry, finds ready escape through the central opening above. The action is simple and effective.

These heads are built in sizes to fit pipes from 1 inch to 20 inches. All sizes above 10 inches are flanged instead of tapped.

### THE CORNELL INTERNAL COMBUSTION ENGINES.

For use in small isolated plants there is a demand for a gas or gasolene engine of close regulation and sufficiently simple in character and easy to operate and maintain for the attendants in such plants who are, as a rule, janitors or porters, men of ordinary intelligence but no mechanical ability. For this service the Cornell Machine Company, Chicago, manufactures the engine which is represented in Fig. 18.

As the illustration shows, it is of the vertical center-crank type, and has the usual features of such engines, poppet valves, hit-or-miss governing and so forth. The cooling water in the jacketing passes around the valves before it reaches the cylinder, thus insuring cool valves. The latter are removable by loosening two screw plugs in the top of the valve casing, this also exposing the ignitor, which is of the electrical wiping spark type. The entering air for each charge passes over the electrodes, serving to keep them clean and cool. When the speed of the engine rises so that the governor cuts off the charge the exhaust valve is held open, thereby avoiding compression and expansion on idle cycles and consequent loss of power by unnecessary friction.

Tests made with an engine of this make supplied with gasolene and of only 2½ h. p., belted to a 1½-kw. dynamo, are claimed to show no noticeable flicker and a variation of less than three-fourths of 1 per cent. of the voltmeter reading, as well as steady deflection of a tachometer on a variation of half the rated load.

The engines are built in sizes ranging from 2½ to 50 h. p.

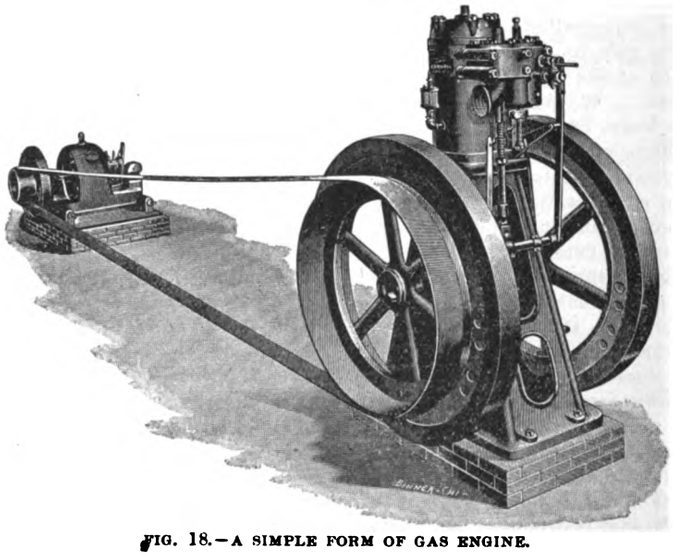

FIG. 18.—A SIMPLE FORM OF GAS ENGINE.

SIGHT FEED DEVICE FOR BOILER COMPOUNDS.

In the lubrication of engine cylinders it was at one time generally customary to introduce the oil by means of a hand pump, or otherwise, in considerable quantities at intermittent times. It was soon found that a greater economy of oil as well as much more efficient lubrication was obtained by introducing it continuously, drop by drop, by means of sight feed devices or constantly driven pumps. In the same way it has been customary to introduce into boilers the compounds designed to prevent the vaporizing surfaces from corrosion and scale in quantities of a quart or more from time to time, and it is now coming to be a recognized fact that the application of the compounds should be continuous in small quantities, rather than intermittent in larger quantities.

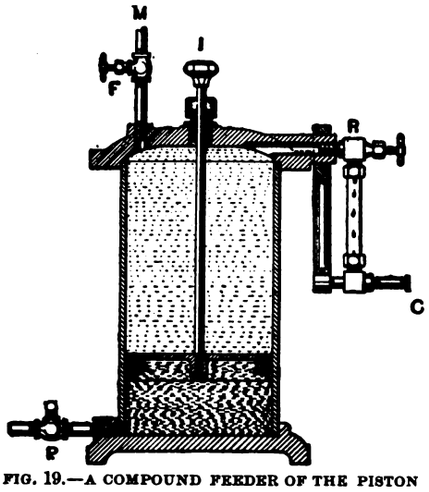

FIG. 19.—A COMPOUND FEEDER OF THE PISTON TYPE.

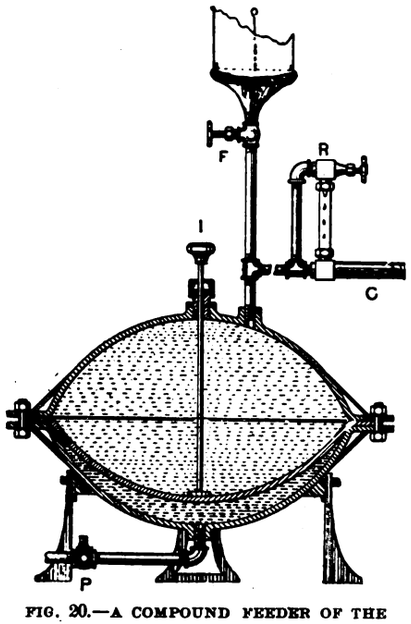

FIG. 20.—A COMPOUND FEEDER OF THE DIAPHRAGM TYPE.

A piece of apparatus for feeding boilers drop by drop with any liquid compound designed to protect the vaporizing surfaces from corrosion and scale, its operation being practically analagous with that of sight feed lubricators on engines, is shown in Figs. 19 and 20, the former showing a piston and the latter a diaphragm form.

When in operation the three-way valve, P, is connected with the pressure side of the feed pump and also with the drain, so that water may be forced in below the piston or diaphragm and again released by manipulating the valve. The space above the piston or diaphragm may be filled with the compound through the valve, F, the piston or diaphragm being simply forced down to eject the water below it by the pressure of the hand upon the top of the indicating rod, I. The upper space once filled with the compound, the pressure of the feed is applied to the lower side of the piston or diaphragm and the compound is driven out through the valve, R, and the sight feed glass to the suction side of the feed pump. By adjusting the valve the required number of drops per minute may be obtained.

A feeder of this kind allows the material to be introduced continuously at any desired rate. The apparatus is made by the Hall Compound Feeder Company of Chicago.

## NEW BOOKS.

The Slide Valve. By W. J. Tenant. Revised and enlarged by J. H. Kinealy. New York: Spon & Chamberlain. 83 pages, illustrated. Price $1.00.

This practical handbook on the slide valve contains some new devices intended to simplify the discussion of this pons asinorum of the student of the steam engine. One of these is a circular diagram of the arcs swept through by the crank during the periods of admission, expansion, exhaust and compression. Another is a diagram containing scales by which the position of the valve on the valve seats can be reduced to the position of the eccentric as well as to the position of the crank. The work is an elementary one, only touching upon the more complicated features of valve gear, such as the Stephenson link and automatic cut-off arrangements, but giving valuable notes explaining some well known valves widely used in this country, such as those of the Watertown, Buckeye and Ide and Ideal engines.

The Internal Wiring of Buildings. By H. M. Leaf. Philadelphia: J. B. Lippincott Company. 195 pages, illustrated. Price, $1.50.

This admirable text book on wiring is unfortunately not as valuable for practical use in this country as in England, the author being an Englishman, and the fittings and arrangements described being those of standard English practice. It is, however, very thoroughly written, handsomely illustrated, and of interest to those going more deeply into the subject of wiring than does the ordinary wireman or contractor, and wishing to know the best practice of other countries as well as our own. The art of interior wiring is perhaps in England behind that in America, the use of iron armoured conduit being comparatively rare, although in some directions, notably the use of concentric systems, English practice has developed in different lines from American and may therefore give valuable suggestions. The work contains the English insurance regulations, as well as those of some of the more important electric lighting companies.

Mechanical Movements. By Gardner D. Hiscox. New York: Norman W. Henley & Company. 380 pages, illustrated. Price $3.00.

This work might well be called a dictionary of electrical movements, powers, devices and appliances used in constructive and operative machinery and in the mechanical arts. It consists of 1649 definitions of mechanical devices, each illustrated by a drawing. A small section, 16 pages, is devoted to electrical appliances in which some 56 attempts at definitions are made. These purport to cover the whole field of electrical engineering, and include a general hodge-podge of telephone, railway and lighting apparatus from a flexible coupling to an electrical sad-iron. A double pole generator is called a single pole generator; a ring armature with 4 coils is called a 4-pole ring armature, and the definitions generally exhibit an utter lack of knowledge on the subject. They are evidently a collection of descriptions of various line cuts that have been found available for reproduction in books, periodicals and other places; these cuts being, as a rule, antiques of the most ancient order. A magneto-electric machine shown is one of the old hand-driven medical machines of twenty-five years ago; under street railway motor equipment there is illustrated a single motor driving the two axles through bevel gears; and the electric car brakes and other devices are just as impracticable and utterly unrepresentative of any commercial work. The only value of a work of this kind is as a sort of a dictionary, in which the index is of fundamental importance. The index of this work is, however, so poor that it is no guide to what little information there is embodied in the definitions.

## OBITUARY.

PROF. ROBERT WILHELM EBERHARDT BUNSEN died August 15th at Heidelberg, Germany, at the age of 88 years. Prof. Bunsen's life has been such a long and active one and so many of his achievements were made in early years that many of the present generation of engineers will be surprised that he was until recently living. Bunsen's name is most widely perpetuated in that common device, the Bunsen burner. Prof. Bunsen did much to advance the scientific comprehension of electrical phenomena, particularly in the early days of this branch of science. He is also known for his original work in the field of spectrum analysis.

## PERSONALS.

MR. GERARD SWOPE, formerly of the engineering department of the Western Electric Company, Chicago, now represents this company in St. Louis, Mo. The office is No. 10 Security Building.

ELECTRICAL MEN HOME FROM ABROAD.—On the first trip of the largest ship in the world, the "Oceanic," arriving in New York, Sept. 13th, were several well known men in the electrical industries who had been abroad. Among them were President Chas. A. Coffin of the General Electric Company, General Manager G. G. Ward of the Commercial Cable Company, and Frank J. Sprague of the Sprague Electric Company.

MR. P. M. HELDT, well known to the readers of the American Electrician through his contributions to its columns, was until recently connected with the Munson Company of La Porte, Indiana, and designed this company's combined gasolene and motor-driven automobiles, recently described in the American Electrician. Mr. Heldt is now associated with the Western Electric Company of Chicago.

A. F. McKISSICK, formerly professor of electrical engineering in the Alabama Polytechnic Institute, has resigned his position and accepted that of engineer in charge of the Pelzer Manufacturing Company's electric plant at Pelzer, S. C., which is by far the largest installation in the South of hydraulically-driven apparatus for the electrical distribution of power throughout a manufacturing establishment.

## TRADE PUBLICATIONS.

A TOAST TO ADMIRAL DEWEY is attractively pictured on a handsomely engraved card sent out with the compliments of the John A. Roebling's Sons Company of New York.

THE GENERAL ELECTRIC AUTOMOBILE COMPANY, Philadelphia, is circulating a small pamphlet illustrating its delivery wagons, run-abouts, Stanhopes and broughans.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has brought out three new bulletins, respectively describing and illustrating multipolar generators and motors, adjustable jaw type switches and plunger type switches.

THE ELECTRIC APPLIANCE COMPANY, Chicago, attributes its success with Noxall annunciators to two points—their simplicity of construction and the price. A circular the company has just issued gives a good description of this instrument.

THE NOVELTY ELECTRIC COMPANY, Philadelphia, is preparing for general distribution a handsome catalogue that will be devoted exclusively to electric light material. This same concern issued last spring an elaborate catalogue on house goods.

THE WESTERN ELECTRIC COMPANY has on the press a bulletin fully describing hot wire ammeters and voltmeters. These instruments may be used upon either direct or alternating current, and are made either for switchboards or of the portable type.

J. B. COLT & COMPANY, New York City, have published a very handsome illustrated catalogue of the Criterion automatic acetylene gas generator, and accessories. The catalogue contains also the complete insurance regulations covering acetylene apparatus.

JOHN S. NOWOTNY, Cincinnati, Ohio, has brought out a new catalogue on his long burning arc lamps. A feature of this lamp is the adjustable armature in the solenoid by which the length of the arc can be changed and the current consumption varied between 3½ and 5 amperes, the candle-power varying with it.

THE ERICSSON TELEPHONE COMPANY, New York City, has started the publication of a small pamphlet entitled the "Ericsson Series." This is intended to cover valuable telephone information in convenient form for reference and future use. Part I of Vol. 1 contains diagrams showing the circuits of series and bridged telephones.

ELECTRIC MINE HAULAGE.—A catalogue upon underground electric haulage has been issued jointly by the Baldwin Locomotive Works and the Westinghouse Electric & Manufacturing Company. The catalogue illustrates and describes the locomotives, and contains tables of dimensions, and of the hauling capacity upon various grades.

THE HOPPES MANUFACTURING COMPANY, Springfield, Ohio, has published a new catalogue of its steam separators and oil eliminators and feedwater purifiers and heaters. The catalogue is illustrated with perspective views of the apparatus described with the shells broken away so that the construction of the devices is made most clear.

THE C. J. TOERRING COMPANY, Philadelphia, manufacturers of the Toerring enclosed arc lamp described in the last issue of the American Electrician, has recently issued an illustrated catalogue covering its 200-hour enclosed arc lamps. The company claims that in no recent lamp tests has it obtained less than 225 hours' life, using one 12x½ in. carbon.

THE AMERICAN REFLECTOR & LIGHTING COMPANY of Chicago is circulating a new catalogue of its extensive line of reflectors and shades, pointing out the merits of the forms and materials used, notably the opal porcelain glass which is semi-transparent, and the corrugated silver glass, which has a high reflecting surface giving a mellow light owing to the diffusion given by the corrugations.

GATES & RANDOLPH, Chicago, Ill., have published a 20-page catalogue in bulletin form of the chief lines of apparatus which they handle and install in their work as engineers and contractors for electric railway, light and power plants. The catalogue describes and illustrates Triumph direct current machines, Warren inductor alternators, Empire instruments, Scheeffer transformers and meters, La Roche circuit breakers and switches, Sterling arc lamps, Bristol recording instruments and Nash gas engines.

THE B. F. STURTEVANT COMPANY, Boston, Mass., has brought out catalogue No. 101, entitled "Steel Plate Planing Mill Exhausters." These machines are adapted to a much wider class of use than the name indicates, as they may be used for the handling of all classes of material light enough to be carried by an air blast. The Sturtevant enclosed motor combined with these exhausters makes a most suitable arrangement for the dust laden locations where such machines work whenever mechanical power is not available.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., has published catalogue No. 997, illustrating its principle types of rheostats and circuit breakers. The line is a comprehensive one, including in addition to the conventional lines of field rheostats, theatre dimmers and motor controllers, some more interesting and special apparatus, such as motor driven dimmers, motor starters with combined automatic no voltage release and interlocking overload circuit breaker, storage battery regulators, printing press speed controllers, etc.

WILLIAM BARAGWANATH & SON, Chicago, Ill., have issued a new catalogue of feed water heaters, and jet condensers of their well-known types. As most users of such apparatus know, they make a closed feed water heater in both the vertical and horizontal types, as well as the plain tubular heater and open heaters, both upright and horizontal, and with and without receiving tanks. The Baragwanath siphon condenser of the jet type requiring no air pump, the vacuum being obtained solely by the fall of the water from the jet to the hot well 34 ft. below, is also listed in this catalogue.

THE ELECTRICAL ENGINEER INSTITUTE OF CORRESPONDENCE INSTRUCTION, New York City, has brought out a catalogue of its electrical engineering, mechanical engineering and other courses. The list of courses is a surprisingly well rounded one, containing besides the elementary or general and popular courses usually desired by students of correspondence schools, a line of advanced technical special courses, such as those in advanced telephony, electric mining, railroad signaling and train dispatching, electrometallurgy, storage battery practice, electro-therapeutics, medico-surgical radiography, etc.

THE MONTAUK MULTIPHASE CABLE COMPANY, New York City has printed a revised price list No. 3 and an "Installation and Specification Handbook." The latter not only describes the cable and shows how to install it by means of complete diagrams of circuits and other directions, but also gives forms for making estimates and methods of making out proposals so that all an installing electrician needs to know in regard to complete installations using this cable can be found in the book. The price list supersedes all others and lists many new styles of cable, besides containing other data useful to the installing electrician.

THE LOMBARD WATER-WHEEL GOVERNOR.—The Lombard Water-Wheel Governor Company, Boston, has issued a pamphlet describing its new type F governor, which has been designed for application to Pelton and other makes of impulse water-wheels, and for the regulation of small turbines. A concise general description of the new governor is given, and also clear instructions as to data to be furnished to the manufacturers when ordering. A letter is printed from the superintendent of the celebrated Redlands plant in California, which speaks in the highest terms of the performance of the Lombard governor in that plant.

THE STRAIGHT LINE ENGINE COMPANY, Syracuse, N. Y., has brought out the tenth edition of its catalogue under date of July, 1899. The catalogue gives an admirable exposition of the peculiarities which have made the Straight Line engine famous, among them the three self-adjusting points of support, the packingless piston and valve rods, the cross-head pin tight in the connecting rod, the long cross-head and short guides, the throttle, the limited expansion piston rings, the flexible strap to the governor spring and the straight uniform frame on each side from cylinder to main bearings, which has given the engine its name.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., has brought out a new catalogue of Dixon's graphite productions. Besides its pure flake graphite, which is of great value for engine lubrication, and its paints which are of value for telegraph and trolley poles, smoke stacks, boiler fronts, etc., quite a number of graphite products are now made solely for the electrical trade. Among these are graphite boxes for baking carbon lamp filaments, etc., as well as graphite "forms" in wedges and other shapes on which to wind lamp filaments, and ground graphite for use in baking the carbons and filaments, its value in this process being to absorb the oxygen which would otherwise attack the more valuable materials. The company also makes its well known resistance rods up to 2 ins. in diameter and 12 ins. in length with any resistance between 1 and 7,000,000 ohms. A special graphite is also made for cementing the filaments of incandescent lamps to the leading in wires. Other forms are made for use in battery plates.

Digitized by Google

THE ELECTRIC RAILWAY NUMBER OF CASSIER'S MAGAZINE.—One of the most elaborate and handsome specimens of magazine literature that has ever made its appearance is this special issue of Cassier's, which was recently published. It comprises altogether 18 articles prepared by 18 authorities in electric railway work, and is if anything an advance on the two remarkable special numbers of the same magazine previously published, viz., the Niagara Power and Marine numbers.

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, has brought out two new bulletins, Nos. 3,002 and 3,003, dated September, 1899. The first lists nearly a thousand different sizes and types of marble tablet boards, comprising a complete line in which practically any board wanted can be found. The second describes the small power alternating current induction motors for single-phase circuits, these motors now being made in sizes from 1/10 to ¼ h. p. for four different frequencies, 6,000, 7,200, 12,000 and 16,000 alternations per minute, making in all 13 different machines of this style, any one of which can be ordered for either 52 or 104 volts.

THE WESTERN ELECTRIC COMPANY has published a catalogue of power motors describing, illustrating and listing its encased, semi-encased and open machines as well as its back-gear motors and motor generators. The Western Electric motor of the enclosed, or as the company prefers to call it, encased type, has one ingenious peculiarity in its mica windows in the covers fastened to the bearing bracket, through which windows the commutator and brushes can be examined at any time. In the matter of field windings this company makes its compound wound motors in two styles termed respectively quarter compound and half compound; the former style, as the name indicates, is one in which the series coils occupy 25 per cent. of the total volume of the field winding, this ratio giving a reduction of the speed by 15 per cent. from no load to full load. In the half compound style the series coils are equal in volume to the shunt, these motors dropping about 40 per cent. of the speed over the rated load range.

WILBUR B. DRIVER & COMPANY, New York City, have issued a price list of "Climax," "Advance" and "D" resistance wires. Complete tables of the electrical and physical properties of the wire are also given. "Climax Wire" has about 48 times the resistance of copper, which is about three times that of German silver and six times that of ordinary steel. This high specific resistance renders it an economical substitute for rheostat work, especially where it is subjected to repeated heating and cooling, which renders German silver brittle and liable to breakage and open circuit. The carrying capacity of the various sizes of "Climax Wire" as well as the resistance per 1000 ft. are given in tables for every 100 degrees up to 1000 degrees F., which indicates the remarkable ability of this material to maintain its physical properties at high temperatures. "Advance" wire has about 30 times the resistance of copper, and its coefficient is practically nil, making it especially valuable for use in measuring instruments. "D" wire has about the same resistance as 18 per cent German silver, and is claimed to be stronger, less liable to corrosion and with a lower temperature coefficient. The catalogue also lists a new steel wire with a remarkably low temperature coefficient, viz., .04 per cent per deg. F.

## BUSINESS NEWS.

THE E. P. ALLIS COMPANY, Milwaukee, Wis., has leased the Lake Erie Engineering Works at Buffalo, N. Y., and expects to have 500 men at work there by September 1.

THE THRONATEESKA ICE, LIGHT & POWER COMPANY, Bainbridge, Georgia, is about to purchase a 75-kw. alternator and a 50-kw. power generator and wishes to receive tenders for the same.

THE MOUND TOOL & SCRAPER COMPANY, St. Louis, Mo., made for the Garlock Packing Company 1,000 souvenir packing tools which were given away at the annual convention of the National Association of Steam Engineers.

PASS & SEYMOUR, Syracuse, N. Y., have opened an office in Boston at 22 Summer St., in the New England Building, where they intend to carry a full stock of their porcelain goods. The new office is in charge of Mr. A. B. Field.

MESSRS. PARTRICK, CARTER & WILKINS, Philadelphia, the manufacturers of annunciators and bells, as well as of other electrical house goods, are arranging to have a complete exhibit of all articles manufactured by them at the Philadelphia National Export Exposition.

A. A. McCREARY, New York City, announces that his business in McCreary's electrical specialties has been taken over by the A. A. McCreary Company, incorporated, which has been formed for the purpose of increasing the facilities for handling the growing business.

MR. J. G. POMEROY advises that he has withdrawn from the firm of McGill, Pomeroy & Co., 317 Dearborn Street, Chicago. Mr. Pomeroy will give the larger portion of his time henceforth to the representation of the Adams Bagnall Company, of Cleveland, in the northwestern territory.

MORSE, WILLIAMS & COMPANY, Philadelphia, have recently finished the installation of three electric passenger elevators and one electric dumb waiter in the National Export Exposition in Philadelphia. The outfit is equipped with all the latest appliances and is in itself an interesting exhibit.

THE CL..G-SURFACE MANUFACTURING COMPANY, Buffalo, N. Y., reports that it has recently established a branch in Johannesburg, South Africa, to meet the increased demand for Cling-Surface in that section from those who have been compelled to run their belts as tight as possible to prevent slipping.

FREIGHTAGE TO THE PARIS EXPOSITION.—Jospeh C. Mount, General Shippng Agent and Freight Contractor, of 4 Lime Street, London, E. C., has made special arrangements for the conveyance of exhibits to and from the Paris exhibition of 1900. He is represented in America by Messrs. Sire Brothers, New York City.

THE PHILADELPHIA MACHINE SCREW WORKS, Philadelphia, reports that its business was never better than at the present time. It is exceedingly busy with general screw and electrical work and owing to the fact that it has recently largely increased its plant, it is better enabled now to fill orders promptly than heretofore.

THE BADT-GOLTZ ENGINEERING COMPANY, Chicago, is the new name of what was formerly known as the firm of Meysenburg & Badt, Mr. Edward A. Meysenburg having retired from the active management and the name of Mr. Wm. Goltz, secretary of the company, having been incorporated in the company's name.

THE NATIONAL ELECTRIC COMPANY, of Milford, Conn., has received a unique order from England. The order is for 50 complete sets of electric bells and fire alarm boxes for Windsor Castle. The company reports that it has received contracts for apparatus for several other almost equally famous structures in England.

THE STILWELL-BIERCE & SMITH-VAILE COMPANY, Dayton, Ohio, has established a branch office for St. Louis and contiguous territory in the Burlington Building in that city. The company will carry at this branch a full line of standard sizes of steam pumps, automatic feed pumps and receivers, air compressors and heaters, which will insure prompt deliveries.

THE HOLMES FIBRE-GRAPHITE MANUFACTURING COMPANY announces that it has secured new quarters in order to accommodate its increasing business, in Germantown, Philadelphia. At the new location modern machinery has been introduced to manufacture the product, fibre-graphite, which will enable the company to turn out this material in greatly increased quantities.

THE GEO. C. TOWLE MANUFACTURING COMPANY, Lancaster, Pa., is at present installing an additional 50 h. p. engine and boiler to meet the requirements of its ever increasing business. It is making a specialty of designing special motors to be direct connected to machinery, and reports having just received a large order for fans to be exported to South America.

THE KELLOGG SWITCHBOARD & SUPPLY COMPANY has moved its factory and offices into new quarters on the corner of Congress and Green Streets in the city of Chicago. The new quarters contain three floors, each about 175 ft. x 35 ft. in size, and give much more room for the work of the company than did the works at Highland Park, which will soon be discontinued.

THE NATIONAL WATER TUBE BOILER COMPANY, New Brunswick, N. J., has recently changed hands and come into the possession of a number of local business men whose purpose it is to again bring the National boiler into active competition with other makes. Mr. C. A. Schenck, who has been with the company for several years, is secretary and manager of the new concern.

THE ROSSITER-MACGOVERN COMPANY has been incorporated under the laws of New Jersey, with a capital stock of $250,000, and headquarters at Newark. The stated objects of the concern, whose principles are well known in the electrical field, are to build power houses, construct electric railways, etc. The incorporators are Frank Macgovern, Van Wyck Rossiter and Isaac M. Sutton

THE MANHATTAN GENERAL CONSTRUCTION COMPANY, manufacturer of the well-known Manhattan enclosed arc lamps, has removed to its new factory at Plane and Orange Streets, Newark, N. J., where its general offices are also located. The Manhattan Company, however, retains a sales office at its old address, No. 11 Broadway, Bowling Green Building, New York City.

THE CHICAGO DYNAMO & MOTOR CO., Chicago, is making a specialty of small dynamos for incandescent lighting, especially in units of 120 to 150 lights and also of motors from ¼ horse power to 15 horse power. This company claims to have met with a gratifying success on its one horse power motor, which is made especially for wholesale grocery houses, to be used on coffee grinding mills.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., furnished the engine, generator and motors for the electrical equipment of the power and machinery department of the World's Dispensary Medical Association of Buffalo. The plant is quite an extensive one, consisting of an American Ball compound engine direct-connected to a generator with both belted and direct-connected motors.

THE STAR ELECTRIC COMPANY, Binghamton, N. Y., reports business very brisk in all lines, and an increasing demand for its annunciators and other specialties, besides a large sale for Emerson fans, Anchor specialties and porcelain goods which it is pushing extensively. The company also mentions that it is at this time in position to quote particularly interesting prices on porcelain insulators, tubes and cleats.

THE GENERAL INCANDESCENT LAMP COMPANY, Cleveland, Ohio, has succeeded

Digitized by Google

to the business of the Fort Wayne Lamp Company, having purchased the assets of the old concern. The new company is closely associated with the other company, the name of which it so nearly follows, viz., The General Incandescent Arc Light Company of New York City; the president of the lamp company being Mr. Samuel Insull.

THE VULCANIZED FIBRE COMPANY, Wilmington, Delaware, finds that its business has grown to such an extent that it has been compelled to add to its already large works. The new building will be a three-story brick addition to the old factory and will be 135 x 30 ft. in size.

THE BOARD OF DIRECTORS OF THE CUTTER COMPANY, Philadelphia, tendered Mr. Henry B. Cutter, president of the company, an informal dinner on the occasion of his recent return from abroad. Mr. Cutter gave an interesting resume of his trip, describing some of the important electrical establishments which he had visited. He expressed himself as gratified at the popularity of the Cutter Company's apparatus abroad.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., made quite an event of the annual convention of the National Association of Letter Carriers. In honor of the occasion the schools had a large monogram I. C. S. with letters of incandescent lamps in front of their building. As this institution has such an enormous amount of mail the carriers from all parts of the country are interested in inspecting the home office.

THE WATERTOWN ENGINE COMPANY, Watertown, N. Y., has opened an office in Chicago at No. 900 Fisher Building, in charge of Mr. F. H. Pond. Among recent sales they report one of their new vertical direct connected high-speed engines to the Deering Harvester Company, and three vertical cross compound condensing engines to the Pennsylvania R. R. for their Ft. Wayne shops; also two 7x7 vertical engines direct connected to Westinghouse generators.

THE MICHIGAN ELECTRIC COMPANY, Detroit, Michigan, has undertaken a rather unusual piece of work in the complete equipment of a yacht with a gasolene engine driving a generator with storage battery, searchlight and complete fixtures. The same craft will be fitted by the same company with an electric revolution indicator and an engineer's signal system, giving it altogether one of the most complete electric plants ever designed for a yacht.

THOMAS J. JOHNSTON has opened an office in the Park Row building, New York, for the practice of law, his special province being the conduct of patent cases, either in the courts or the United States Patent Office. Mr. Johnston was admitted to the bar 17 years ago, and for six years past he has been retained by the General Electric Company in its patent department as an assistant to Frederick P. Fish, the well-known patent counsel. He has a wide acquaintance among electrical men.

THE MANHATTAN GENERAL CONSTRUCTION COMPANY has, since its purchase by Mr. Geo. Westinghouse, removed its general offices to the new location of its works at Newark, N. J. The company reports that its new direct-current lamps are giving service which has brought in many orders, two dry goods stores in the Northwest having ordered respectively 87 and 142 lamps, another order of 60 lamps having been obtained from the American Bridge Works, Chicago.

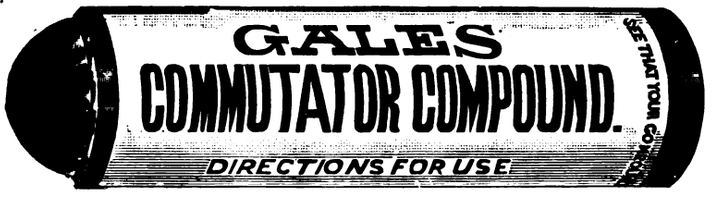
THE JEWELL ELECTRICAL INSTRUMENT COMPANY, Chicago, has been organized to take over sales of the electrical instruments formerly sold under the name of the McIntosh Battery & Optical Company. Mr. Edward W. Jewell is president of the new concern and Mr. Geo. M. Willis is general sales manager. These instruments will be manufactured as heretofore by the McIntosh Battery & Optical Company and under Mr. Edward W. Jewell's personal supervision.

THE A. B. PITKIN MACHINERY COMPANY, Providence, R. I., announces that it has recently acquired the records, drawings, patents and parts, finished and unfinished, of Armington & Sim's engines, and is completing arrangements which will enable it to fill orders for repairs or the renewal of parts of the large number of engines of this type in use. The company also lists a number of second-hand engines and boilers which it has for sale in addition to new engines and boilers of all powers.

THE H. W. JOHNS MANUFACTURING COMPANY, New York City, will make at the Street Railway Convention an extensive exhibit of its line of molded mica overhead insulation, its car heaters and its "Noark" indicating fuses for 500-volt circuits. The fuses will be shown in operation, the company promising something in this line ahead of anything previously exhibited. The exhibit will be in charge of the company's Western representatives, the Manville Covering Company, Chicago.

BAUGHER, KURTZ & COMPANY, LTD., is the name of the re-organized firm of York, Pa., formerly known as Baugher, Kurtz & Stewart, manufacturers of heavy iron and brass work and notably of turbine water wheels. Mr. W. F. Bay Stewart has retired and Mr. Geo. U. Wiser has joined the company and become the treasurer. The company is adding to its works a new shop to handle the large amount of business offered. Among recent shipments was one of a large turbine wheel to Barcelona, Spain.

WESTINGHOUSE, CHURCH, KERR & COMPANY have recently closed the greatest sale of gas engines as yet recorded. Twelve engines were ordered, aggregating 3000 h. p., for a cement factory in Kansas, the total price being $91,000. The company has also closed some large contracts for complete traction installations, one notable one being that of the Toledo, Fremont & Norwalk Electric Railway, which will run a distance of 60 miles with one central power plant generating high tension three-phase currents, and seven rotary sub-stations.



THE MICHIGAN ELECTRIC COMPANY, Detroit, Michigan, carried out the entire work on the special illuminating feature of the Elk's Carnival, held in Detroit, August 21st to Sept. 2d. Something over 2000 incandescent lamps were used on arches and other decorations. The lamps were entirely in color, the lightest being amber colored, which were centered around the entrances of the arches, the deeper-hued lamps forming a framework about them. The special illuminating effects were carried out in accordance with the ideas of Mr. Jos. E. Lockwood, president of the company.

THE MORRIS ARC LAMP COMPANY, Chester, Pa., has brought out a folder illustrating and describing its perfected "1900" Morris enclosed arc lamps. This is an improved form of the lamp described in the American Electrician of last May, the casing being adapted to outdoor use. The regulating mechanism of this lamp consists of a concentric solenoid operating a "tilting ring" clutch working on the carbon itself, the current being introduced to the carbon through fine copper brushes secured to the upper carbon holder and bearing with an easy pressure upon the interior walls of the carbon tube.

THE FALCON ELECTRIC MANUFACTURING COMPANY, New York City, is a newcomer in the electrical field, which intends manufacturing a complete line of switches and switchboards as well as a general line of electrical specialties. Mr. H. O. Swoboda, an engineer well known in his own line, who has been for the past seven years identified with the General Incandescent Arc Light Company, will have charge of the factory as general manager and superintendent. The officers of the company are Mr. Edward Leissner, President; H. O. Swoboda, Vice-President, and L. E. Frorup, Secretary and Treasurer.

CHICAGO RHEOSTAT COMPANY.—While the Chicago Rheostat Company has removed from Chicago to New York, branch offices with a large and well assorted stock of rheostats will be maintained at 1012-1013 Monadnock Block, Chicago, to accommodate a well developed Western business, but

# A COMMUTATOR NECESSITY.

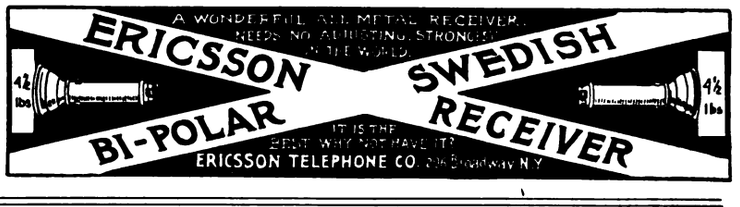
the factory and main office will be in New York, in charge of Mr. E. W. Hammer, at 397 to 407 East 33d Street. While the growth of this company has shown a splendid increase, it is believed that the domestic business can be handled as well from New York with a decided advantage in the handling of foreign trade.

THE DETROIT LUBRICATOR COMPANY, Detroit, Mich., has, for purposes of record and identification, numbered its sight feed lubricators consecutively from No. 1 upwards, so that the number appearing on a lubricator shows how many had been manufactured up to its time. On Sept. 15, 1899, the company reports that it had completed lubricator No. 460,000. When it is considered that as a rule only one lubricator is used on an engine this figure gives eloquent testimony to the general use of the Detroit lubricators in this and other countries. The company's present output of sight feed lubricators alone amounts to over 5,500 per month, and it also reports a rapidly growing trade in the new style glass oilers and oil pumps.

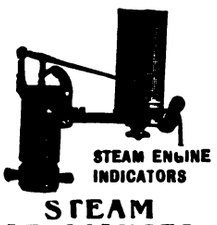
THE HANSON VAN WINKLE COMPANY, Newark, N. J., is developing a new field for the use of its electro-plating machinery in the application of an electrolytic process for removing metal, constituting it the reverse of electro-plating. The metal to be removed is the spelter and brass around brazed joints, the greatest need for a process of this kind being in the jointing of bicycle frames. Methods heretofore used involved the treatment of such joints in an acid pickle, which is injurious to the steel parts as it is likely to leave a tendency to rusting. The electrolytic process is accomplished in a strictly alkaline solution, which is harmless to the tubing. The process leaves the metal bright and clean for enameling.

THE ANNUAL CLAMBAKE OF THE AMERICAN ELECTRICAL WORKS, Providence, R. I., was held on Saturday, Sept. 9th, at the Pomham Club near Providence, about 400 guests being present. The party met at the Narragansett Hotel and made the trip to the club in specially chartered trolley cars. The usual athletic sports were indulged in and were followed by the clambake dinner. The menu, following the style of the invitations, was printed on sheets of frosted copper. Major R. S. Brown of the Westinghouse Company served as toastmaster and addresses were made by Eugene F. Phillips of the company, Congressman A. B. Capron, President F. A. Gilbert of the Boston Electric Light Company and others. Each guest was presented with a handsome souvenir in the form of a miniature loving cup.



A STORAGE AIR BRAKE SYSTEM.—The value of air brakes on electric cars and the fact that such small train units hardly warrant the complexity of either an axle driven or motor driven compressor, has brought upon the market an air brake system in which the air is compressed by a stationary compressor at the power station or other convenient point and carried at a pressure of 300 lbs. in storage tanks upon the car, which are recharged at convenient times. The system is being introduced by the G. P. Magann Air Brake Company of Detroit, Michigan. The particular advantages are the simplicity and low first cost of the car equipment, the noiselessness of operation, the higher economy of a large stationary compressor, etc., which will be apparent on consideration of the fundamental principles of the system.

MR. GEORGE W. PATTERSON, the general Western agent of the American Circular Loom Company, has developed various specialties which go to make up a very interesting evening's entertainment, all accomplished with electrical devices. Mr. Patterson is an expert swinger of Indian clubs and these he illuminates with lamps of different colors controlled by an attendant behind the scenes, the clubs giving, when in rapid motion, very beautiful effects. Other features are an electrical storm, an electrically illuminated rainbow, a telephone with megaphone attachment and the various high tension effects than can be obtained with an electrolytic interrupter. Mr. Patterson desires to obtain a number of other interesting electrical devices to exhibit at these entertainments, and the manufacturers of such are requested to correspond with him at his office in the Marquette Building, Chicago, Ill.



THE MICHIGAN ELECTRIC COMPANY, Detroit, Mich., has been successful in securing some important contracts and orders for parties it represents, these including a contract to J. G. White & Company of New York City from the Detroit, Rochester, Romeo & Lake Orion Railway for complete power house equipment, including two 250 h. p. B. & W. type Aultman & Taylor water tube boilers, two 300 h. p. Ball & Wood special design tandem compound engines, two 200 k. w. Crocker-Wheeler railway generators, one Crocker-Wheeler motor-driven booster, one Westinghouse 90 k. w. alternator, motor driven, a complete switchboard and complete equipment of condensers, pumps and all of the details required for a high grade power house. The company has also secured an order from the Toledo, Fremont & Norwalk Electric Railway for over 21,000 Atkinson protected rail bonds, this order being one of the largest ever placed in the country for similar goods.

THE AMERICAN ELECTRIC SPECIALTY COMPANY, New York City, is placing on the market an instrument designed to locate grounds or short circuits, particularly in telephone or other lead covered cables. The design and principle of the instrument are similar to those of the company's direct reading ohmmeter. The principle is that of the slide wire bridge, a fall of potential being established on the grounded or crossed conductor by connecting its two ends to a battery. The same battery is connected to an exposed resistance wire of the instrument placed over a graduated scale. The telephone, which is used in place of a galvanometer, is then connected between the ground and a conducting point, which can be tapped upon this resistance wire. When the telephone is silent the point under the tapper has the same potential as the ground, and therefore the drops of potential to either side of the point are to each other as the drops in the cable tested to either side of the ground. The scale reading thus gives the ratio of the distance of the ground to the length of the cable.

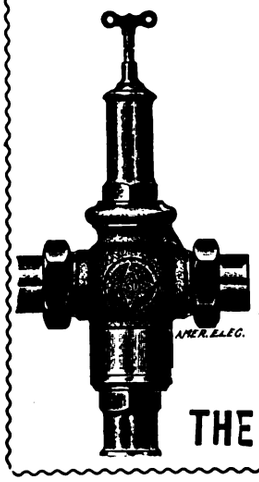
COLOR UNDER ARTIFICIAL LIGHT.—A prominent American artist, who has made a great many experiments in lighting paintings with incandescent light, claims that it is not alone the quality of the light, but to a certain extent its quantity, that affects the color values. This is explainable on the score that the artificial light is weak in some colors and must, as a whole, be strengthened in order to give sufficient intensity to those shades to make them prominent. Yellows, for instance, which under ordinary gas or incandescent light are almost white, retain their true value under a strong and evenly diffused light. This theory is substantiated by the experience of I. P. Frink, New York City, in lighting paintings in the large art galleries, and his application of the same principles to store window lighting gives merchants practically the daylight colors of their goods at night. This is especially important to dry goods houses, for their windows are filled with daintily colored dress fabrics, which attract attention primarily by their colors. Frink's patent window reflector gives a very strong and evenly diffused light, yet no lamp is in view to distract the eye by its concentrated brilliancy; and under this light color values hold their own in a way that is surprising.

THE ELECTRIC SIGNAL AND BURGLAR ALARM CLOCK is the name of a piece of apparatus which on first presentation conveys the idea that the designer had assumed that burglars might be expected at a certain definite hour and had utilized an alarm clock for forestalling them. The clock is simply a good time piece, designed to run thirty days without rewinding and fitted with time contacts and a plug board such that any bell wired to it may be rung at any predetermined time. It is thus a great convenience in hotels for awakening guests and announcing trains, in stores and factories for announcing the time of taking up and leaving work without giving a general alarm, and even in private houses for use as an alarm clock and announcing the time for the various domestic duties of the day. The burglar alarm feature of the clock is simply a switchboard by means of which any or all of the various bells wired to it may be connected with the burglar alarm circuit. The same switchboard allows any push button to be transferred at any time to any bell, the clock thus serving as a sort of central exchange for making up any desired push button and bell circuit. The apparatus is made by the Electric Signal Clock Company, Galion, Ohio, for which the Central Electric Company, Chicago, is the Western sales agent.

THE AMERICAN STEEL & WIRE COMPANY'S ELECTRICAL PRODUCTS.—The recent financial changes in the iron and steel manufacturing industries have been so numerous and kaleidoscopic that many users of the products of the companies in this line of work have not become familiar with the new status of the manufacturing houses. Contrary to the assumption which might be created by its name, the work of the American Steel & Wire Company is by no means confined to the production of iron and steel wires or their products. By the absorption of the Washburn & Moen Manufacturing Company the larger organization inherited one of the world's most important manufactories of bare and insulated copper wires for all electrical purposes. With the immense plant at Waukegan, Ill., only 35 miles north of Chicago, at which much of the copper wire is produced, the American company enjoys exceptional facilities for catering to the wants of the trade in the West, giving as it does the same prestige in the western field that is enjoyed by the Washburn-Moen department at Worcester, Mass., in Eastern territory. The merging of this company into the American Steel and Wire Company means simply a further step in the progress whereby with unlimited resources, continued investigation and improvements a still greater superiority is assured in the production of all forms of electrical wires, rail bonds, etc. At the Waukegan plant special attention is given to the manufacture of the well-known "Extra BB," "BB," and "Steel" telephone and telegraph wires and copper wires for electric lighting and street railway plants in all their various forms. The company also has extended its facilities at Worester for the manufacture of its various types of rail bonds and its complete line of insulated wires. The general offices of the company are located in "The Rookery," Chicago, with branch offices in New York, Worcester, St. Paul, St. Louis, Cleveland, Denver, San Francisco and other cities.

## THE BEST SHOOTING.



The shooting in Iowa, Minnesota and South Dakota this year promises to be very good as the rainfall in all these states was abundant. The best localities for chicken and duck shooting are on and tributary to the lines of the Chicago, Milwaukee & St. Paul Railway. A copy of a recent publication issued by the passenger department of that road can be had on application to Geo. H. Heafford, General Passenger Agent, Chicago, Ill., and enclosing three cents in stamps for postage.

# American Electrician.

Vol. XI. New York, November, 1899. No. 11.

## THE ELECTRICAL EQUIPMENT OF THE LARGEST SHIP AFLOAT.

### A Description of the Electric Lighting, Electric Motor and Telephone Systems on the Steamship "Oceanic."

By far the largest ship afloat, or now building, is the "Oceanic" of the White Star Line, which made her first voyage to this side during the month of September, 1899. The electrical equipment of this ship is of interest from its connection with this prodigy of marine architecture alone, and in this case there is added interest in this country due to the fact that the apparatus is of foreign design and construction, and exhibits many features differing from American practice. The following description will aim to bring out some of these interesting peculiarities, which may serve in the way of suggestions to those designing marine equipments in this country.

But little need be said of the ship in general, so widespread has been the discussion of her main points in the public press. With a length over all of 704 feet, 12 feet more than that of the "Great Eastern," a displacement of 30,000 tons at 32 feet draft, and a capacity for 17,000 tons of cargo and 410 first class, 300 second class and 1000 third class passengers, she by far outclasses, in point of magnitude, all previously built ships. Her main driving equipment is not designed to give her the great speed that might be obtained with a ship of this size. Indeed, it has no greater power (28,000 h. p.) than that of some smaller craft, but it is intended to bring her into port on the seventh

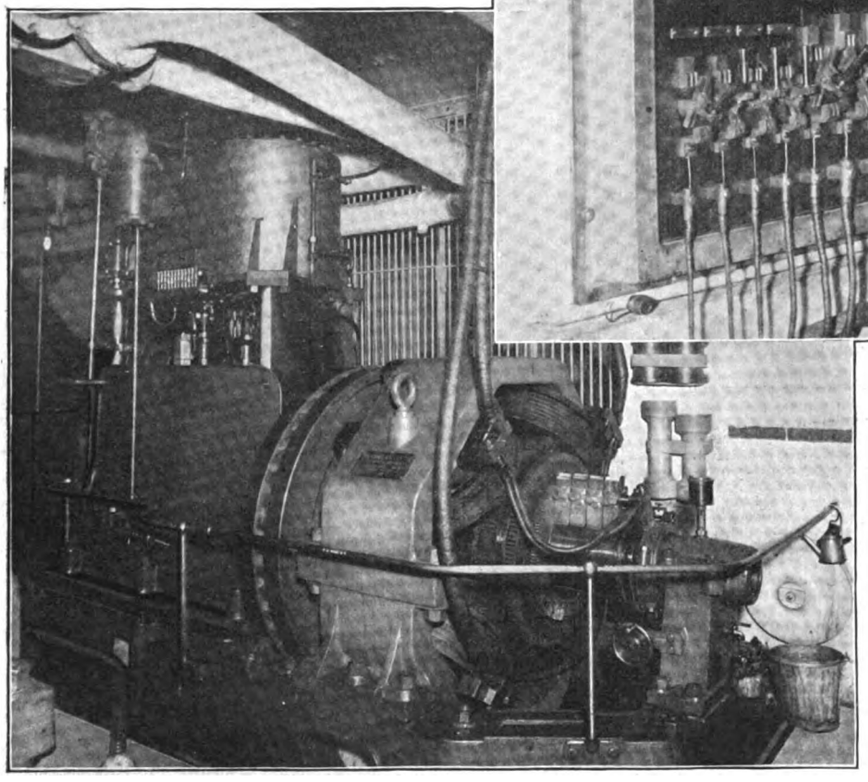

FIG. 1.—ONE OF THE GENERATING UNITS OF THE "OCEANIC."

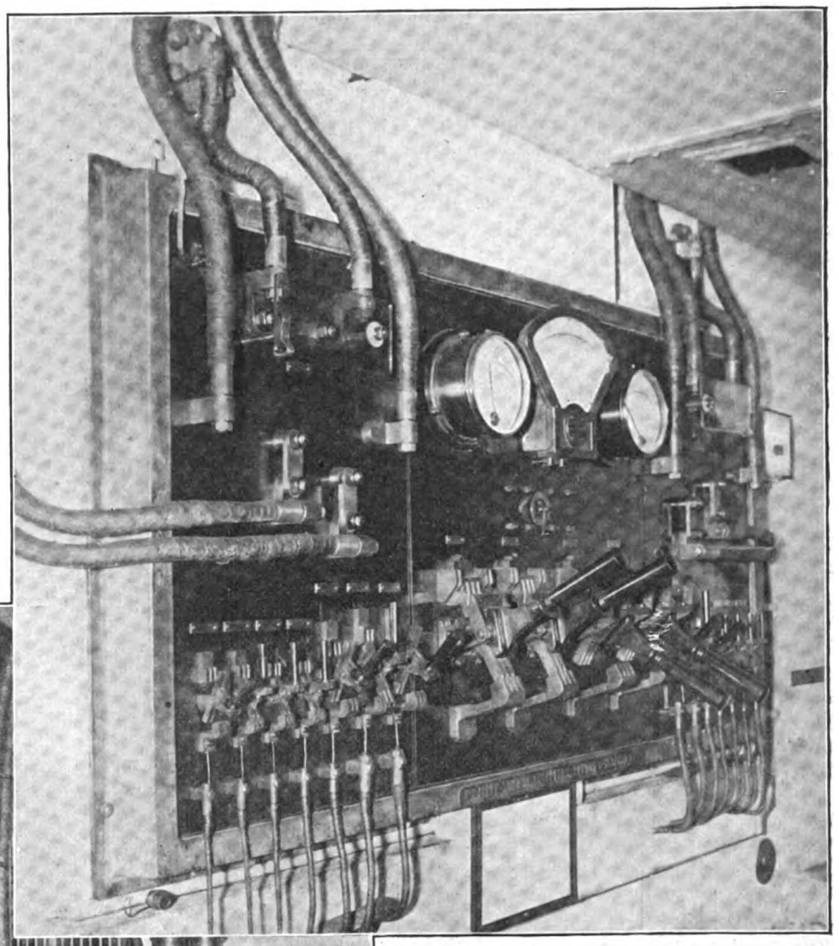

FIG. 2.—ONE OF THE SWITCHBOARDS, SHOWING THE GROUNDING PLATES ON THE BULKHEAD OVER IT.

Digitized by Google

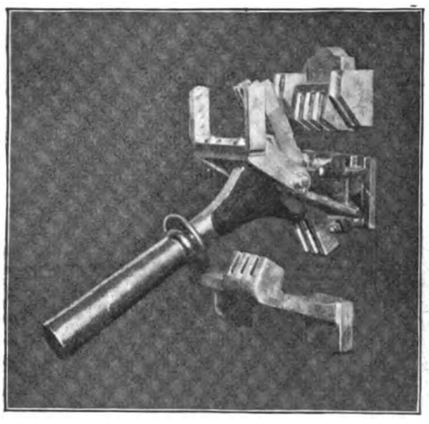

FIG 3.—ONE OF THE MAIN SWITCHES.

morning from her date of sailing with schedule regularity.

The electrical generating plant consists of four direct-coupled machines, which are mounted aft of the main engines and on the intermediate platform, at an elevation a few feet below the lower cylinder heads of the main engines. This location is far superior to that often adopted, viz., lower down in the ship and between the main shafts, since it is above the water line, lighter, more airy and less cramped. The four machines are arranged with fore and aft shafts in two pairs, one to either side of the longitudinal water-tight bulkhead which divides the port from the starboard engine room. Each unit consists of one cross-compound vertical engine of a very simple character, the two cranks being set 180° apart so that the two piston valves, one for each cylinder, can be driven by a short crosshead, operated by one simple eccentric between the cranks.

Contrary to all American practice, but in conformity with English custom, the speed control is accomplished by a throttle, which is in this instance driven by a shaft governor. The dynamos have no field rheostats whatever, so that the adjustment of the voltage and the division of the load when running in parallel must be accomplished by varying the speed. This is provided for by means of a spring connected to the linkage by which the shaft governor operates the throttle valve. The tension of this spring, which helps to balance the centrifugal force of the governor weights, can be adjusted by means of a screw and hand wheel, thereby varying the speed at which the governor will open or close the throttle valve. This mechanism is shown in Fig. 4.

The engines take their steam from the main boilers through a reducing valve which drops the pressure to 100 pounds per square inch, and exhaust, when at sea, into the main condensers, and when in port into the auxiliary condenser. A peculiarity of the main engines of the "Oceanic" is the fact that no cylinder oil is used and consequently no filters are used for removing the accumulations of oil from the feed water returning from the hot well to the boilers; a practice differing from that customary in other ships. On this account the use of cylinder oil is not permitted in the engines driving the dynamos and it has been found that under this condition the governing throttle valves, which are of the balanced piston type, with no packing rings, bind so that the governors cannot control the speed. For this reason the control of the voltage and the division of the load are adjusted by hand operation of the stop valves of the engines, the load being sufficiently constant to permit this rather primitive method of operation.

Each engine is direct coupled to a 60-kw. four-pole generator, the general design of which can be seen in Fig. 1. These machines differ from American dynamos in several features. They are compound-wound, the series turns being put on two opposite poles only and over

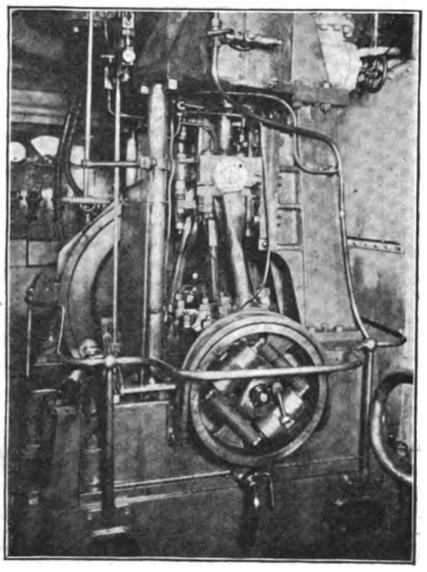

FIG. 4.—AN END VIEW OF ONE OF THE ENGINES SHOWING THE GOVERNOR AND ITS CONNECTION TO THE THROTTLE.

the shunt coils, the two other poles being wound only with the latter. The extension of the lower casting of the machine, which runs out to the bearing at the commutator end, is slotted, and to this slot there can be bolted a tool holder with longitudinal and cross feeds, for turning down the commutator at any time. The armature windings have spiral end connections, the coils being series connected, and each machine has only two brush holders instead of the four which might be used on four-pole machines.

One of the most interesting parts of the equipment is the pair of switchboards, one in each engine room, a view of one of which appears in Fig. 2. The central and main instrument on each board is a voltmeter with scale reading only from 80 to 120 volts; the normal voltage of supply at which the lamps are rated being exactly 100 volts. Flanking the voltmeter on each side is an ammeter, one for each generator, beside which may be seen the main fuses, under glass covers, the lower part of the board being occupied by the main and feeder switches. The general scheme of the board may be described as follows:

There are two sets of bus bars, one for the lighting circuits and one for the power circuits, there being two bus bars in each set, one positive and one equalizer, there being no negative bus bar whatever on the boards. This is due to the fact that the hull of the ship is depended upon for a return circuit on the negative side of the system. The negative lead of each dynamo is carried to the switchboard and there through an ammeter and single-pole fuse, from which a cable two or three feet long leads off above the board to a circular contact plate about nine inches in diameter, bolted directly to the bulkhead, against which the switchboard is set. It is notable that there is no space behind the switchboard to get at bus bars or other connections, the board being fixed close to the bulkhead, all cables leaving from the front so that the necessity of getting behind the board is removed.

The main switches are of a peculiar type, shown in detail in Fig. 3. The main circuit on the positive side is carried through a vertical piece in the center of the switch fitted with multiple knives on each end designed to engage suitable jaws. This piece is rotated on a horizontal pivot at its center by means of a toggle action operated by the handle. On the upper part of the movable part of the switch is a U-shaped contact which closes the equalizer circuit. There are two such switches for each generator, one connecting with the power and the other with the light bus bars, instead of the double-throw switch which would be used

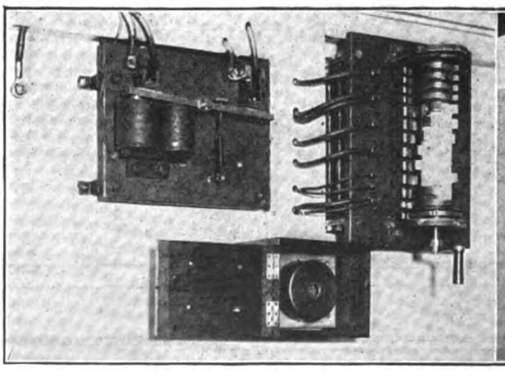

FIG. 5.—THE CONTROLLER, SWITCH AND MAGNETIC BRAKE SWITCH OF THE PROVISION HOIST.

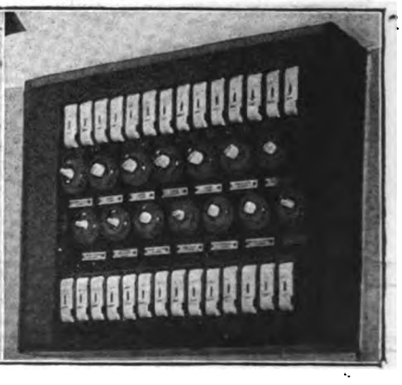

FIG. 6.—ONE OF THE DISTRIBUTING PANELS.

Digitized by Google

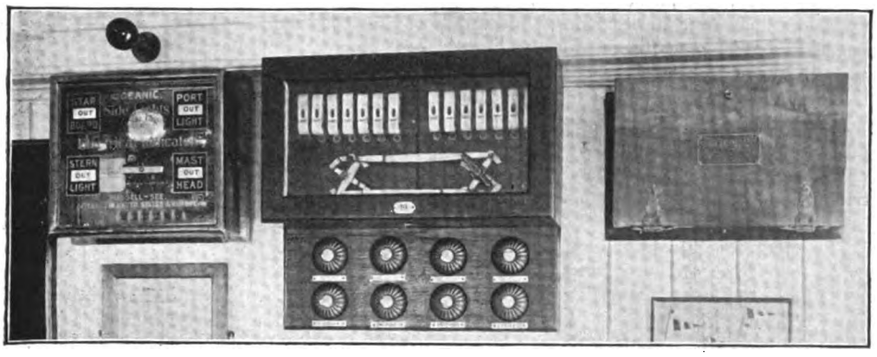

FIG. 7.—A VIEW IN THE WHEEL-HOUSE SHOWING THE SIGNAL INDICATOR, THE SIGNAL LIGHT AND TELEGRAPH CIRCUIT PANEL WITH ITS THROW-OVER SWITCH FROM A PORT TO A STARBOARD FEEDER, AND THE CASE CONTAINING THE AUTOMATIC WHISTLE APPARATUS.

in this country. On this account a bus-junction switch is unnecessary. The parallel working of the two switchboards, however, requires bus-junction cables, four in number, for the power and light equalizer and positive buses. The ends of these four cables entering the front of the board, two on each side, may be plainly seen in the illustration of the board, Fig. 2. The cables terminate in links by which they may be disconnected in case it is desired to dismantle one switchboard while the other is in operation.

All the feeder switches are, of course, single-pole, since the wiring throughout the ship is purely single-pole, every lamp, motor or other current-consuming device being connected directly to the ship's plating for a return circuit. The feeder switches are, as the illustration shows, of the same type as the main switches, but on a smaller scale. Immediately below them are the fuses and the name plate over each switch specifies not only the cross section of the copper in that feeder but the proper size of fuse. The fuses are of tinned copper cables, made up in all cases of wire No. 33 English standard wire gage, different capacities being obtained by varying the number of strands in the cable or the number of cables between the fuse terminals. For instance, one plate specifies 5 strands, another 9, another 20 and still another 40. Circuits requiring more current than can be supplied by a 40-strand cable have two or more cables in parallel. Similarly the main fuses are specified on their accompanying name plates, each fuse consisting of two strips of tinned copper, each 1 inch x .013 inch in cross section (the rated current of each dynamo being 600 amperes), the two strips laid together between the bolted contacts. The switchboard attendant is protected from the violent blowing of the main fuse by a heavy cover of plate glass placed over it and swiveled so that it can be readily turned back.

The load carried by this generating plant consists of some 2000 incandescent lights, a dozen motors driving ventilating fans and some 200 electric heaters in the first-cabin state rooms, besides various electric cooking devices, such as grills in the kitchens, water heaters in the bath rooms and numerous small motors scattered about for operating such loads as a provision hoist, the spits in a roasting oven, a power-driven rotary hairbrush in the barber shop and other minor apparatus. Some of the special applications of the current call for apparatus of American manufacture. The controller of the motor-driven winch of the provision hoist, shown in Fig. 5, was made by the Crocker-Wheeler Electric Company and the electric heaters scattered throughout the state rooms are those of the American Electric Heating Corporation.

The current is carried throughout the ship in what are known abroad as lead-covered and armor-clad cables, the term armor-clad signifying a wrapping of steel wire similar to that used on submarine cables. This does away with the necessity of either molding or iron-armored conduits, making the installation of the wiring a comparatively simple and cheap undertaking.

The main feeders run to branch boxes like that shown in Fig. 6, containing snap switches and porcelain removable fuse holders from which single-conductor branch cables run from lamp to lamp, the socket shell of each lamp, which forms one contact with the base, being grounded by its support upon the plating or framing of the ship.

The telephonic equipment of the vessel is of the heavy, substantial type adopted in the British Navy. On the bridge immediately forward of the wheel house and protected from the weather by a roof and front wall are the engine-room telegraphs and four telephone instruments. A view of two of these, mounted between the windows of the wheel house, is shown in Fig. 8. The instrument proper consists of a heavy, cast-iron box with two openings, normally closed by a rotating cover. By moving this to the open position the proper connections of a microphone and telephone receiver are made. The upper opening communicates with the receiver and the lower with the transmitter. One of these four instruments communicates with each engine room, one with the after docking bridge and the other can be connected by means of the switch shown just below it in the illustration to either

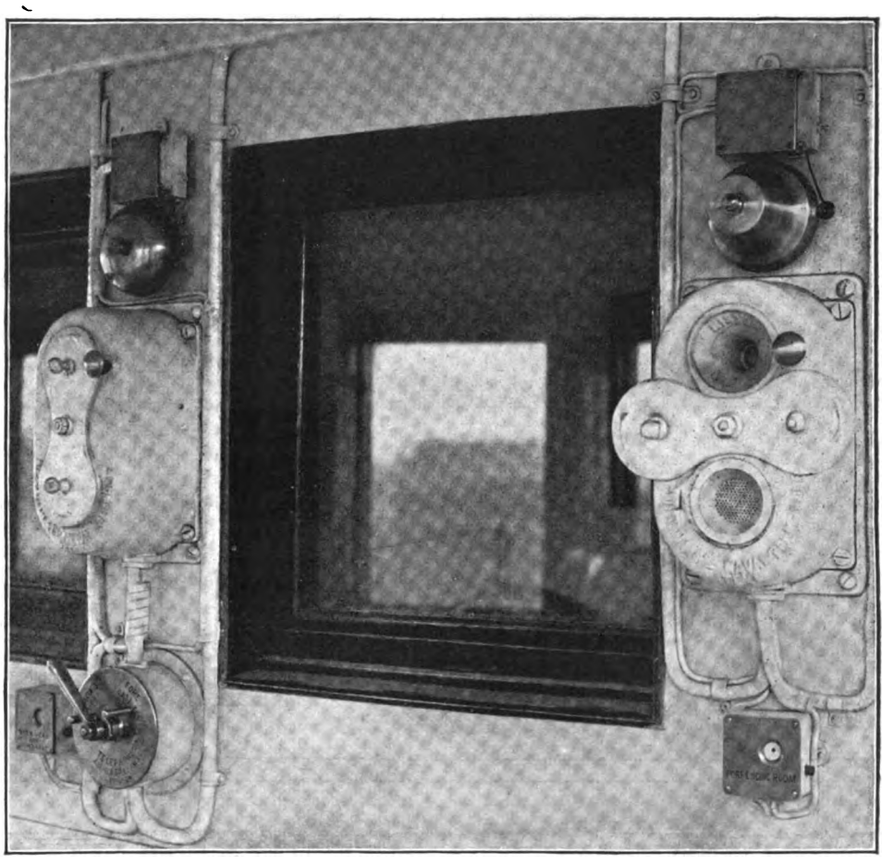

FIG. 8.—TWO TELEPHONES ON THE BRIDGE, ONE CLOSED AND ONE OPENED.

Digitized by Google

the forecastle head or the crow's nest, these two points being so far distant from the bridge on this mammoth ship that telephonic connection with them is necessary. The same illustration shows the operating handle of the electrically controlled whistle which also is fitted with the American made apparatus of the Signal & Control Company of Brooklyn for blowing the whistle either by hand or automatically at prouer intervals in case of fog.

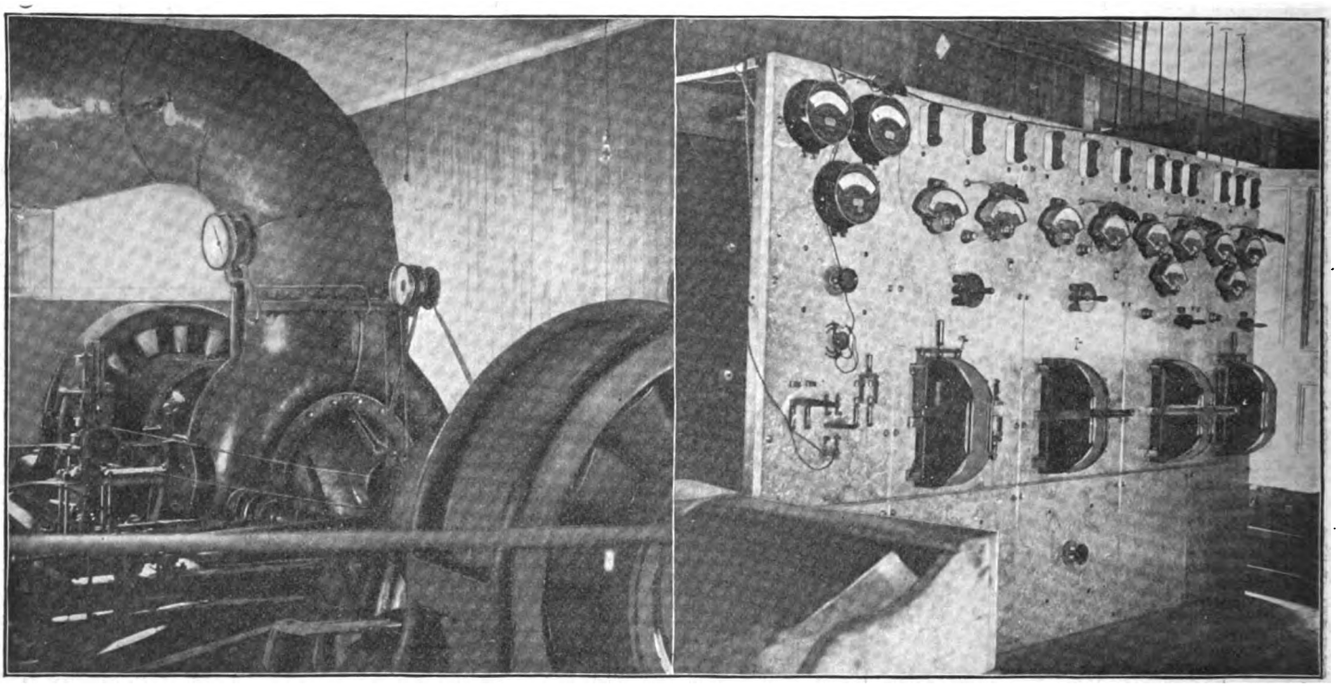
Within the wheel house is still another piece of American apparatus, viz.: the Russell-See electric indicator (made by the Wm. Porter's Sons Company) for giving visible and audible warning in case any one of four main lights is extinguished, these four lights being the starboard and port side lights and the stern and masthead lights.

The electrical equipment of the ship was built by W. H. Allen, Son & Co., London and Bedford, England, and is in charge of Mr. R. J. Thomas, chief electrician, to whom thanks are due for the information given above.

The most forcible impression conveyed by an inspection of the steamship "Oceanic" is one of solidity, reliability and durability, features that characterize her electrical equipment, as well as her construction throughout.

# An Electric Railway in Central America.

BY DAN WELLS CASEMENT.



In San José, Costa Rica, during the month of April, 1899, the first electric railroad in Central America was opened for regular service. San José, a city of about thirty thousand inhabitants, is the capital of Costa Rica, and one of the most progressive cities in Central America. There is an abundance of water power throughout the whole of Costa Rica and for a number of years the principal cities have had electric lights, both arc and incandescent, the current being generated by water power.

Within the last year the Costa Rica Electric Light and Traction Company, Limited, has taken in the three plants at San José besides one in Cartago, and has replaced many of the old machines and instruments and added machinery of suitable capacity to operate the railway. The tramway is, at present, about three miles long, but will probably soon be extended to one or two of the suburban towns. There are four cars, each equipped with two G. E. 58 motors, controllers and electric brakes. The grades are quite heavy, maximum 7 per cent., and the cars, especially on Sundays, are generally heavily loaded, but as yet not a single motor has been burnt out.

When taken hold of by the Costa Rica Electric Light and Traction Company, Limited, the following three plants were in operation in San José: the Anonas plant, about three miles from the city, which contained two 55-kw. Westinghouse single-phase alternators supplying part of the incandescent light, and one Wood 100-light arc machine, supplying part of the street lights; the Rio Torres plant, situated on a river at the north end of the city, with one General Electric 75-kw. 2200-volt monocyclic alternator, supplying the remaining incandescent lights and an arc light plant at the east end of the city with two T. H. arc machines which supplied the remaining street lights.

The new company has enlarged the Anonas plant and made of it the principal station which now supplies power for the tramway and a large portion of the incandescent and arc lights. The old water power at this plant was no more than sufficient to operate the old equipment so it was necessary to use another stream, which is considerably larger than the old one but its head is only 90 ft., while the head of the old power is 180 ft. The old stream, The Maria Aguilar, is brought to the power house through a 36-in. flume, 500 ft. in length, and has an estimated capacity of 270 h.p. The water from the Rio Tiribi is carried through a long ditch to a small reservoir and thence to the turbine through a 56-in. pipe, 500 ft. long.

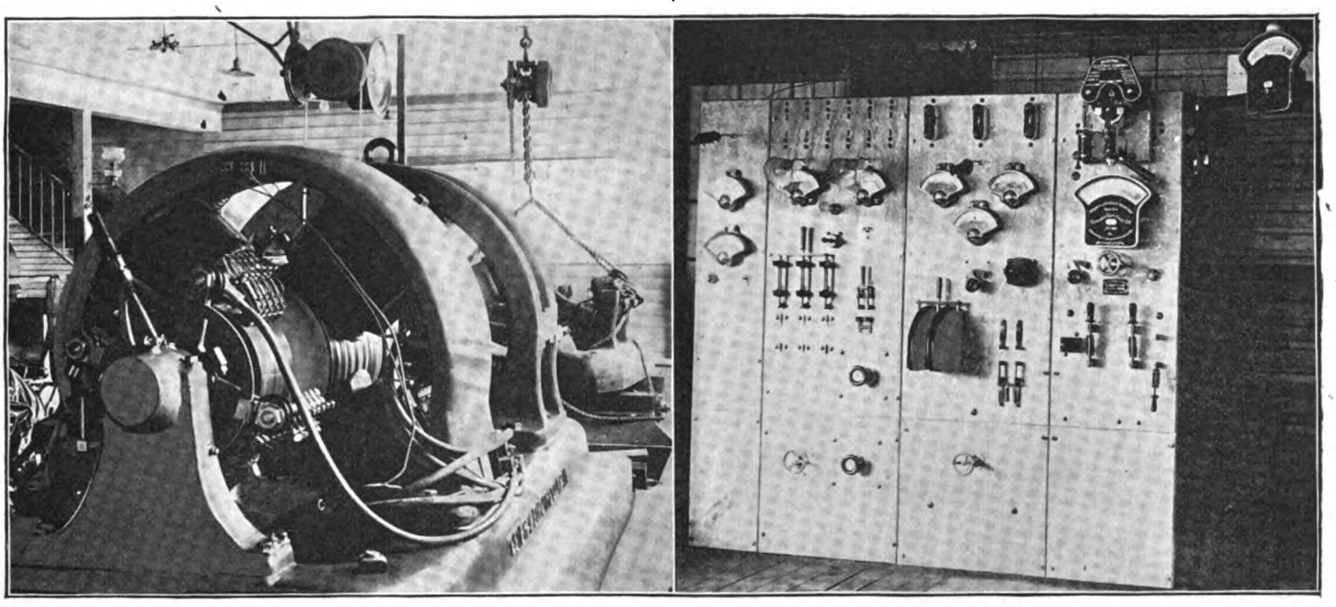
The two Westinghouse alternators have been removed, the building has been lengthened and a 450-h.p. turbine on one shaft with two 300-kw. three-phase General Electric generators has been installed. The turbine was built by the James Leffel Company and is controlled by a Lombard water wheel governor. The generators are coupled to the turbine by means of Hill friction clutches, and either is large enough to operate the tramway and the incandescent lights at the same time. The 75-kw. three-phase generator, originally at the Torres plant, but now direct belted to one of the old Pelton wheels at Anonas, takes care of the incandescent load after midnight when the tramway is shut down and but a small portion of the lights are in circuit. A new No. 9 Brush arc dynamo of 125 lights capacity, 1200 c.p. each,

THE TURBINE, GENERATORS AND SWITCHBOARD OF THE ANONAS PLANT.

Digitized by Google

has been installed at this plant in place of the Wood machine which has been removed to the Torres station and is held in reserve. The switchboard of blue Vermont marble is made up of six panels, three machine panels, two feeder and one exciter panel. The two feeder panels are for the tramway and incandescent light service, respectively. One panel controls the two exciters; these are of 12½ kw. each, one being belted to the main turbine and the other to the double Pelton wheel which drives the 75-kw. alternator. With this switchboard any possible combination between machines and lines can be made. The arc machine is also provided with a plug board for controlling the arc light circuits.

The three-phase current from the Anonas plant is transmitted to the Rio Torres Station at 2200 volts by three No. 1 mains, where it is led without transformation direct through the switchboard to the synchronous motors of the motor-generator sets. Each of these sets is made up of a three-phase synchronous motor of 100 kw. direct-connected to an 85-kw. direct-current generator on the same base. This generator furnishes direct current to the railway at 550 volts and also excites the synchronous motor. The switchboard at this station is at present a five-panel board. The railway generator panels are of the customary type with a large Weston station voltmeter swung to the side, and each is provided with a magnetic blow-out circuit breaker at the top of the panel. The synchronous motor panels are similar to the machine panels at the main plant, being equipped with Thomson alternating voltmeter and three ammeters, quick break main switch, fuses, field rheostat and exciter switch. The fifth panel is one on which is mounted a synchronizing device and a special switch for starting either of the motor-generator sets from the direct-current side when the other is already in operation. The Wood arc machine, now installed at this plant is direct belted to a double Pelton wheel designed to develop 50 h.p. under a head of 58 ft. The water for this wheel is taken from the Torres River, a considerable distance above the plant, and, like most of the water powers near San José, is used in the coffee curing establishments before reaching the reservoir from which the turbine is supplied.



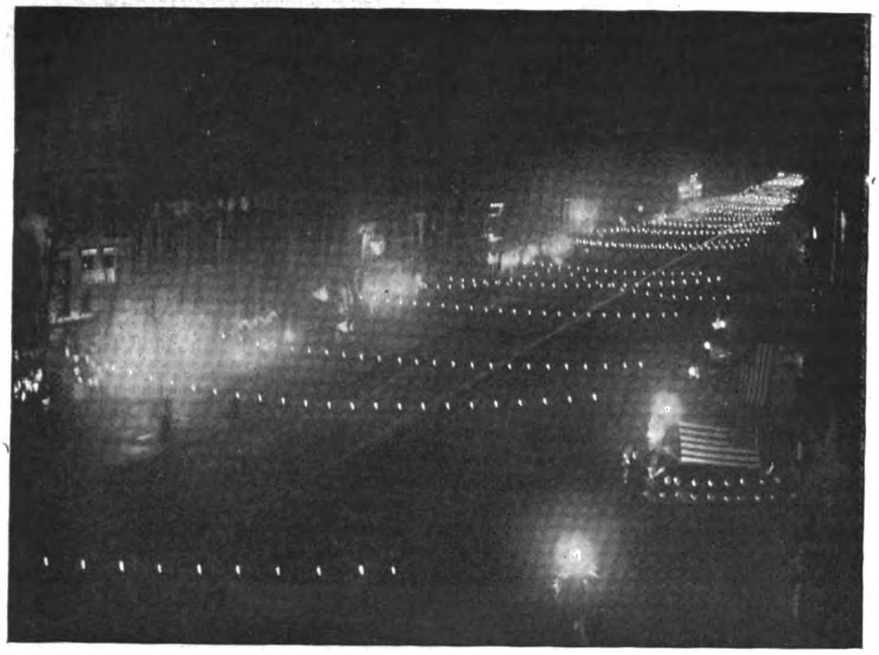
Over the machines in the illustration of the motor-generator on this page, there may be seen supported from the ceiling a special form of tachometer. This is belted to the shaft of the machine below it. Owing to the fact that the motor is of the synchronous type, this tachometer indicates a speed exactly proportional to that of the generators. It is provided with contacts wired to an alarm apparatus intended to give audible indication should the speed of the generators rise or fall to such an extent as to require the attention of the attendant to the machines in the sub-station.

The old arc lighting plant is not of sufficient interest to deserve description, except that it was the first plant in the country and has been in operation seven years. Originally, this plant contained two Thomson-Houston dynamos, one of 50 and the other of 30 lights capacity. All arc lights are of 1200 c.p. 6.6 amperes. The power at this station is derived from a double Pelton wheel under a head of 50 ft.

The Cartago plant, operated by the same company, is situated at Cartago, a town of about 8,000 inhabitants and the original capital of Costa Rica. This plant contains the T.-H. 30-light arc machine, originally in the San José arc station, one Westinghouse 60-light arc machine and one of the Westinghouse single-phase alternators, originally at the Anonas plant. All these machines are belted to Pelton wheels.

The incandescent light current in San José was originally supplied to the buildings from a large number of small transformers at 52 volts. These transformers have all been changed and now 104 volts are used. In the principal part of the city all buildings are supplied from three-phase secondary mains. These mains are connected at frequent intervals to 7.5-kw. transformers, which transform the current from 2200 to 104 volts.

The main line of the tramway is from the Costa Rica Railway Station, through the central part of the town to the Sabana, a large tract of public land on the western outskirts of the city, and used as a park. There are also two short branches, one to the cemetery and one to the Houses of Correction. All track through the city is laid with 72-lb. girder rails on steel ties. Outside of the city 58-lb. T rails with hard wood ties are used. The rail joints are special 36 in., 6-hole, bonded with Atkinson 0000 safety rail bonds. All poles are of iron and the overhead construction is supported from flexible brackets. The trolley wire is No. 0, fed at frequent intervals from a No. 00 feeder.



THE MOTOR-GENERATOR AND SWITCHBOARD OF THE TORRES STATION.

The opening of the tramway excited great interest among the natives, a great part of whom had never seen an electric railway, and now they regard as indispensable what a few months ago did not exist to them. They are very fond of riding and a large number ride on the tramway, as they have for years on the railway, merely for amusement.

The Costa Rica Electric Light and Traction Company, Ltd., is an English company, and was promoted and organized through the energy of Mr. Minor C. Keith, who was the builder of the Costa Rica Railroad, and to whom the country is indebted for much of its development.

It is to Mr. H. T. Purdy, of the General Electric Company of the U. S. A., the manager of the company, that I am indebted for the details of the equipment.

# The Electrical Illumination in San Francisco.

BY CLARENCE L. CORY.

The electrical illumination in San Francisco, in connection with the reception to the First California Regiment on its return from the Philippine Islands, was in many respects the most extensive illumination ever arranged for temporary use. On the two evenings of the illumination the business portion of the city seemed a vast exposition; the many colored incandescent lights along the main streets and on the principal public buildings reminding one of the electrical illuminations at the World's Fair. The Citizens' Committee arranged and planned the public illumination, and its efforts were ably seconded by many large business firms and the newspaper offices. The private electrical displays were numerous and extensive; many of them operated entirely from isolated plants. The City of Stockton installed a 500-light plant, complete, in San Francisco, solely for the occasion to operate the lights used in its display. This was necessary, because the great demand just at this time for lamps and electrical energy made it impossible to carry out the scheme, using power from the San Francisco stations.

For the general illumination 9630 sixteen c. p. lamps and two 75-ampere searchlights were installed and operated from the central station of the San Francisco Gas & Electric Company. This is a three-wire 110-volt, direct-current system, with an auxiliary storage battery. In addition to these lights between one and two thousand lamps were also operated from this station for private displays. This large additional load was met by the station men very successfully, as the load upon the plant during the Christmas holidays has been even greater than it was at this time. The maximum amperes during the illumination was 23,400, while in December of last year the load was 26,000 amperes.

The illumination of Market Street from Eighth Street to the Ferry building, a distance of two miles, was, in many respects, the most interesting. Incandescent lamps were strung across the street, 24 in a row; these strings of lamps being spaced 50 feet apart along the street. At the intersection of cross streets the row of lights were elevated in the center, and these suspended rows contrasted beautifully with the strings across the street. Four thousand six hundred lamps were used in this way along Market Street, and the scheme of connecting in the different sections is shown in Fig. 1. Underground three-wire mains extend along Market Street, the feeders coming in at cross streets. Electric light and telephone poles, however, extend the entire length, and upon these were strung three No. 6 B. & S. copper wires. The different sections of lights were connected in on these wires, as shown, service switches being placed where needed on the poles. The section of lamps marked A is controlled by switch A; the section of lights in each case being designated with the same letter as the switches. Either switch marked D controls both sections of lights, D and D. It will be noticed that the underground neutral is directly connected with the over-head

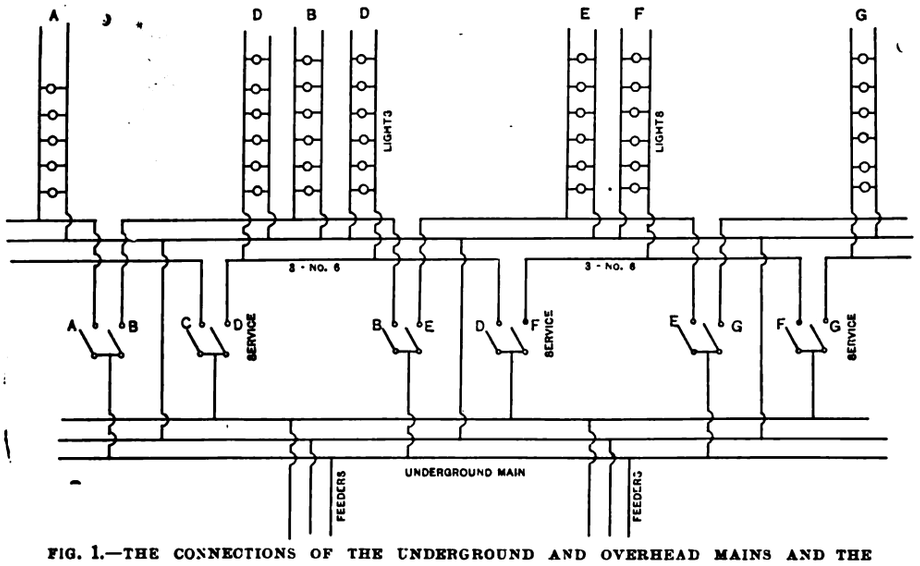

FIG. 1.—THE CONNECTIONS OF THE UNDERGROUND AND OVERHEAD MAINS AND THE ARRANGEMENTS OF SWITCHES.

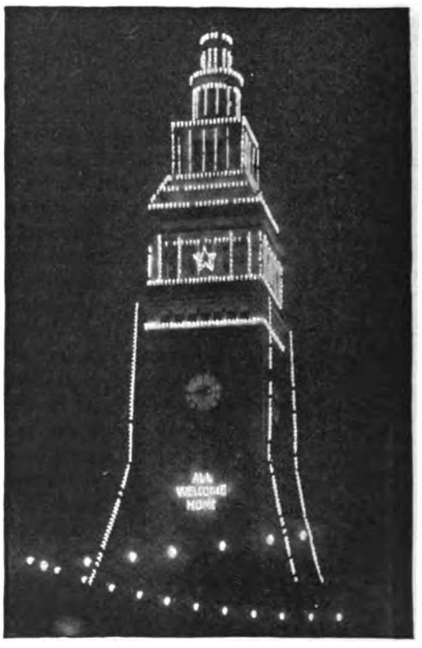

FIG. 3.—THE TOWER OF THE FERRY BUILDING.

Digitized by Google

neutral, the lamps placed in on each side giving a perfect balance to the system.

In each string of 24 lights a fuse was placed, the fuse block in many cases being simply a small piece of wood in which were inserted two ordinary wood screws. The fuse wire was stretched between these two screws and connections made to the No. 14 B. & S. bare copper wire, to which the lamp receptacles were connected. As enough receptacles could not be obtained in the short time allowable, 5000 wooden sockets were made for this work and in no case failed to give satisfactory service. In this planning it was, of course, well understood that rain at this season was practically impossible, but the dense fog which was experienced during the installation did not interfere in the least with the operation of the lights. For temporary work, finished in such a short time, the results were very good; not more than twenty-five lamps, out of the entire number installed, failed. The illustration at the head of page 506 is a photograph giving an idea of the effect of the streamers of lights across the street.

On the tower of the Ferry building 2088 lamps were used. This building just at the foot of Market Street is shown in Fig. 3. From the bay the tower was the only portion of the illumination to be seen, while looking down Market Street the tower was the culmination of the street lighting, producing a splendid effect. The interior of the Ferry building was lighted from the plant of the Mutual Electric Company, the beautiful artistic effect of the lighting of the east nave being shown in Fig. 4.

On the dome and upper columns of the City Hall 3000 lights were installed. The great height of the dome and its elevation near Eighth Street made it the most conspicuous building of the illumination. Fig. 5 gives a good idea of the form of the building and the arrangement of the lights.

The most extensive as well as the most beautiful private display was the "Examiner" building. Three thousand lights were used, operated from the isolated plant in the building. Red, white and blue incandescent lamps were used with beautiful effect, the entire scheme being most admirably planned. All of the construction work and wiring in connection with this display was done in the very best manner possible, and could have been used for an indefinite length of time.

## THE ADVANTAGES OF LONG FILAMENTS IN INCANDESCENT LAMPS.

When it was recognized by Edison and his co-workers some twenty years ago that the incandescent lamp was not suited for series work, but should be run on multiple constant-potential circuits, it was at once seen that these constant-potential circuits should be of as high a voltage as lamp construction would permit in order to make possible the distribution of the current over any reasonable distance from the dynamos. After considerable experimenting it was found possible to make lamps of a resistance high enough to withstand 100 volts, and this, with a margin of a few volts for full measure, making it 110 volts, came to be the standard recognized pressure of incandescent circuits.

During the twenty years since that time the incandescent lamp has been the object of as elaborate investigation and experimentation as any other one product of the mechanical arts, an enormous amount of time, money and labor having been spent in its development, and with no mean results; but even at the present day, although lamps can be made for 240 volts, difficulties are encountered in making as good a lamp for the original standard pressure of 110 volts as can be made for lower pressure.

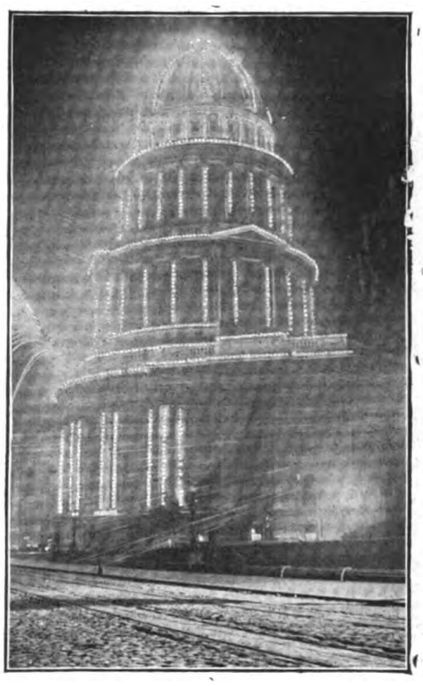

FIG. 5.—SAN FRANCISCO CITY HALL, SHOWING THE LIGHTING OF THE DOME AND COLUMNS

One of the difficulties in the way of raising the voltage of incandescent lamps may be illustrated as follows: Assuming that the lamp is to be of 16 c. p. and of 3.5 watts per candle, its total consumption of power will be 16x3.5, or 56 watts. If burned on a circuit of about 56 volts this power will require 1 ampere and the resistance of the lamp filament will have to be about 56 ohms. If, however, it is to burn on a circuit of 112 volts the power can only be kept down to 56 watts by cutting down the current to ½ ampere and the resistance of the lamp will have to be raised to 224 ohms. Thus it will be seen that doubling the voltage increases the necessary resistance 4 times; which is in accordance with a general law of purely resistive apparatus that the resistance must be varied as the square of the pressure to maintain the absorbed power constant. If the lamp is designed for a 220-volt circuit the current will have to be reduced to about ¼ of an ampere and the resistance will have to be raised to the extremely high value of practically 900 ohms to give the same economy of current. As the resistance of the carbon falls with increased temperature, the resistance cold is practically twice this, or, in the last case, 1,800 ohms.

The only way to obtain the high resistances of from 200 to 300 ohms necessary for lamps of 100 to 120-volt circuits is by using either a material of high specific resistance or of great length and fine diameter. Extended experiments in the di-

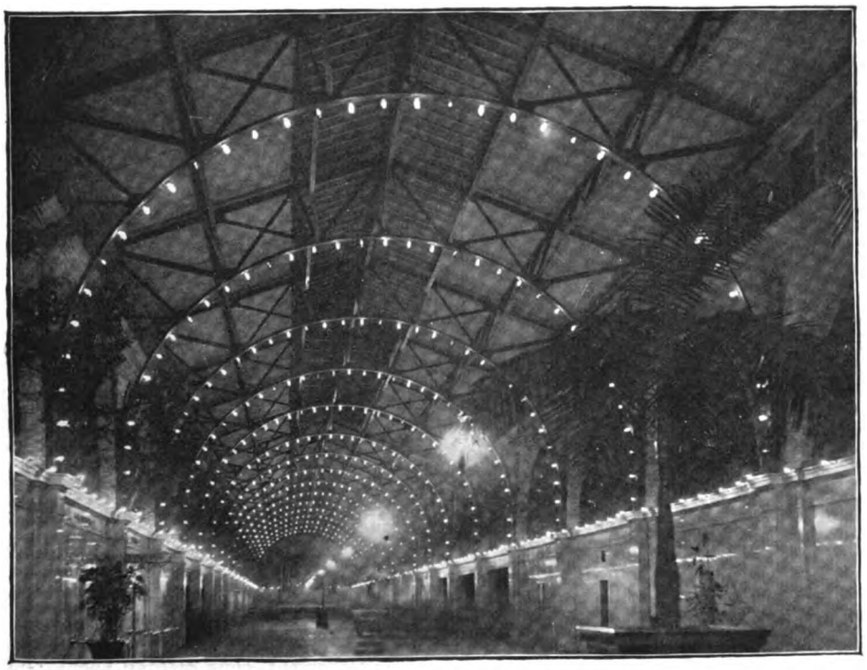

FIG. 4.—A VIEW OF THE INTERIOR OF THE FERRY BUILDING AT THE FOOT OF MARKET ST., SAN FRANCISCO.

Digitized by Google

rection of finding a suitable material of high specific resistance by means of incorporating more highly resistive substances with carbon, or otherwise, have uniformly proven in vain, the only material as yet found available being carbon in two of its allotropic forms. One of these is a variety similar to very dense charcoal, and formed by the carbonization of the original cellulose thread of which practically all filaments nowadays are made. This form is known by lamp makers as "base" carbon. The other is a form of carbon closely resembling ordinary graphite.

All lamp filaments must contain as a foundation a central core of the former, or "base" carbon, filaments constituted wholly of graphite being impossible to make, since the graphite can only be obtained in the filament form by depositing it upon a skeleton structure of "base" carbon. This deposition is done by means of what is called the "flashing" or "treating" process. The carbonized cellulose thread is raised to high incandescence by electric current in a chamber through which is passed a current of gasolene vapor. The white-hot filament decomposes the hydrocarbon vapor, depositing the carbon as graphite upon its surface.

The "base" carbon has about six times the specific resistance of the graphitic carbon, so that filaments consisting wholly or largely of the former can be made much shorter and thicker for the same resistance than those containing a greater percentage of graphite. Unfortunately, however, the "base" carbon is much poorer in the qualities of economical light emission and life. This is not due, as many suppose, to any difference between the light-giving powers of graphite and charcoal; in fact it is generally admitted that all substances, no matter what their color, white, gray or black, shine with the same intensity when raised to the same temperature of incandesence. But the graphite gives to the surface of the carbon a gray, metallic, steel-like appearance which can be plainly seen in all new lamps, and this gray surface, in conformity with a general law of physics, radiates much less heat when raised to a given temperature than does a dead black or sooty surface such as that of the "base" carbon or that of an old lamp in which the surface of the graphite may have been reduced to the charcoal form. A filament therefore with a metallic gray surface requires less energy to supply this heat waste and raise it to the proper temperature of incandescence, such as for example as to radiate one candle power for every 3½ watts supplied, hence the superiority of the graphite for the economical emission of light.

Another superiority of the flashed or treated filament is mechanical. The graphite tube or sleeve which surrounds the "base" carbon is more dense and stiff than its central core, and hence holds the filament more rigidly against vibrations which tend to throw it against the glass, and also prevents it from sagging when the lamp is burned in a horizontal position. The graphite tube, deposited as it is at a high temperature, is a good resistant of the disintegrating effects of heat, and maintains the filament probably after the core of "base" carbon within it is broken down, thus greatly prolonging the life.

As stated above, the graphite is a good conductor of electricity as compared with "base" carbon, and hence if much of the cross section of the filament is graphitic the diameter of the whole will have to be small and the length great in order to obtain the necessary 200 or 300 ohms. The greater the amount of graphite and the less the amount of "base" carbon the better is the lamp for reasons pointed out above, and the general rule may be laid down that for a given voltage a lamp with a long filament is better than a lamp with a short filament, provided—and this is an important provision—the long filament is properly supported.

From the inception of the industry until

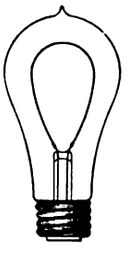

FIG. 1

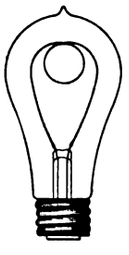

FIG. 2

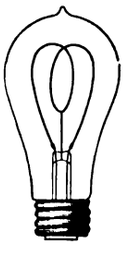

FIG. 3

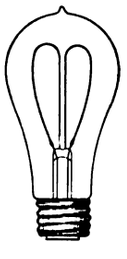

FIG. 4

a few years ago most incandescent lamps had filaments of the plain loop or horseshoe type, such as is shown in Fig. 1 of the accompanying cut. The filaments were thick and short, and little or no treatment was employed. As the superiority of the longer type became apparent the filament was given a loop or coil which allowed its length to be increased without enlarging the bulb, and its percentage of graphitic low-resistance carbon to be increased with it, so that this filament took the familiar form shown in Fig. 2. A variation upon it was the addition of more turns in the coil.

While this form is still made, it is largely giving way to another type developed by increasing the diameter of the coil and anchoring its lowermost point as illustrated in Fig. 3, this being known as the oval anchored type. This allows a further increase of the length and percentage of low-resistance graphite and is made in spite of several disadvantages. One of these is the impossibility of practicably anchoring the filament during the process of flashing so that unsupported this process cannot be carried on at as high a heat as is desirable without badly warping the filament. The graphite deposited is more dense and stable with the higher temperatures of flashing which cannot be obtained on the oval anchored filament. The cement used at the anchored point also causes trouble. This point being distant from the glass supporting the anchor wire and being heated in two directions and cooled in only one rises to a high heat, throwing off gases within the bulb which combine with the carbon on the surface of the filament to darken the latter, thereby tending to spoil the metallic gray finish which gives the lamp a high efficiency by reducing the amount of energy necessary to maintain the filament at the proper temperature as pointed out above. In spite of these faults, however, the perfected oval anchored type is far superior to its predecessors, solely because a greater proportion of the filament's bulk is of the purer, denser form of carbon.

A further step in the support of long filaments is taken by making the filament in two pieces connected in series with each other as shown in Fig. 4, which illustrates what is commonly known as the double filament type. This double filament consists practically of two 8-c.p. 50 to 60-volt filaments connected in series with each other by means of a short piece of wire bedded in the glass and cemented at its two ends respectively to one end of each filament. In this lamp there is no oval coil to twist out of shape and short circuit on itself. The loop shape of the two filaments allows the deposit of graphitic carbon to be made at a higher temperature, making it dense and hard and durable.

For high voltage lamps, that is, those intended for 200 to 240-volt circuits, mechanical difficulties of course arise in making and supporting filaments of twice the length and half the cross section of those for 100 to 120-volt lamps. The result is that comparatively little or no "treatment" can be applied to such filaments without making their resistance too small, which accounts for their failure to equal 100 to 120-volt lamps in the qualities of efficiency and longevity. Still other expedients of support have to be used with these high voltage filaments such for example as anchoring two points, etc.

An idea of the proportions of graphitic to "base" carbon in modern 3.1-watt, 16-c.p., 100-volt lamps can be gained from the fact that lamps of the oval anchored type are treated down to approximately 1/3 of the original resistance of the base of the filament while those of the double filament type are treated down to less than ¼ of the original resistance, this reduction being accomplished by depositing a tube or sleeve of graphitic carbon with a thickness of about 1/10 of the diameter of the finished filament, thus making about 1/3 of its cross section graphite, the inside 4/5 diameter or 2/3 cross section being "base" carbon.

## SWITCHBOARD CONNECTIONS AND SYNCHRONIZING ARRANGEMENTS FOR POLYPHASE GENERATORS.

In the wiring of the generator panels of switchboards handling polyphase alternators there is an innumerable number of possible combinations of the voltmeters, instrument transformers and plug receptacles and lamps to measure the voltage of the various phases, synchronize the several machines and detect grounds. In the early days of polyphase apparatus each individual plant had its own scheme of connections, and, unfortunately, even now each house manufacturing polyphase machinery not only differs from the others in this regard, but has itself several different schemes of connections. Every dynamo tender in a polyphase plant should be able to trace the circuits of his switchboard and understand the purpose of each wire and connection so as to be able to trace trouble when it occurs or renew or replace the wiring when it becomes deranged. The following description of several arrangements used by the Westinghouse Electric & Manufacturing Company may help attendants in stations using Westinghouse apparatus to understand the circuits of their boards.

Various different schemes of wiring have necessarily to be used for different types of generating machinery. Two-phase boards must differ from three-phase boards as the number of bus bars is different, as well as the number of phases to which the voltmeter must be thrown. Boards for high tension circuits must differ from those for low tension circuits, as the former require instrument transformers in all cases, while with the latter the instruments may be connected directly to the machine terminals and bus bars.

Fig. 1 shows the general scheme of connections of high tension two-phase 4-wire generators, connected for running in parallel. But one set of bus bars is shown, the added arrangements necessary for two sets of buses being easily worked out for any individual case. The machine terminals are connected through four fuses and a four-pole switch to the buses, there being an ammeter in one leg of each phase. Branching from the two terminals of phase B of each machine are wires leading up to a small switchboard transformer. This transformer in each case feeds a pilot lamp for that machine and leads run from it to a voltmeter receptacle and to the synchronizing apparatus.

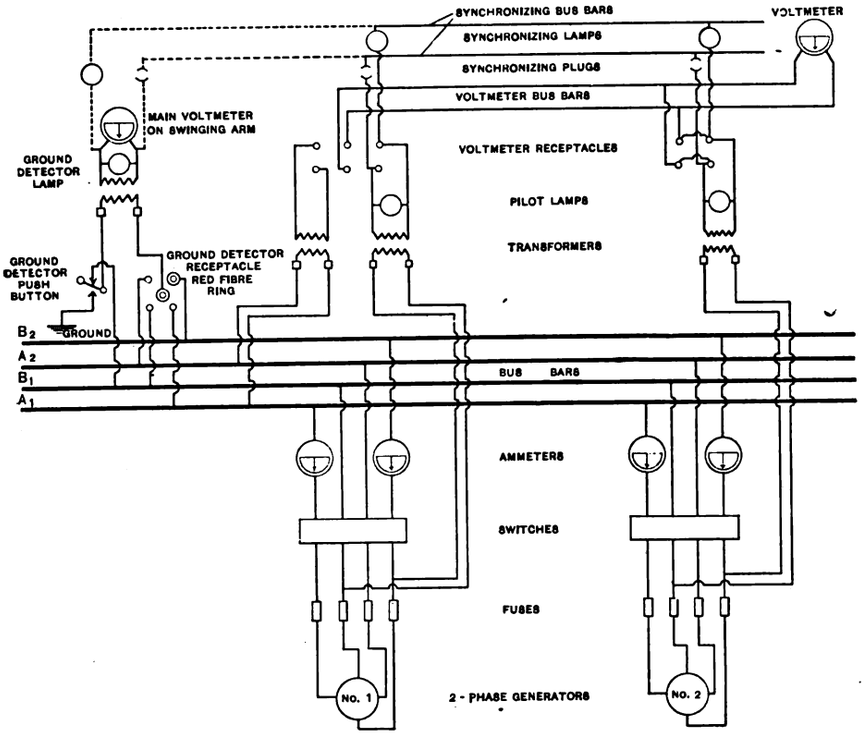

FIG. 1.—THE CIRCUITS OF TWO HIGH TENSION, TWO-PHASE GENERATORS.

Taking up the former instrument first, the connections made when the plug is in the receptacle are shown in that of machine No. 2. One side of the secondary of the switchboard transformer is connected to one of the voltmeter bus bars and the other side to the other, throwing the voltmeter at the right hand side of the diagram on to the secondary of the switchboard transformer connected with phase B of machine No. 2. By pulling out the plug and inserting it in the right hand four sockets of the receptacle on the panel of machine No. 1 the voltage of phase B of that machine will be measured. By moving it over to the left hand four sockets of the same receptacle connections are made between the voltmeter bus bars and the secondary of a small transformer, whose primary is connected across the bus bars of phase A. In this way the voltage of that phase upon the bus bars may be measured at any time.

The synchronizing is done by means of the usual lamps, one on the panel of each machine, and synchronizing plugs, one for each machine. By inserting the plugs on the panels of both machines Nos. 1 and 2 it is readily seen that the secondaries of the switchboard transformers for these two panels are placed in series with each other through the two synchronizing lamps and the synchronizing bus bars. This gives the lamps the usual beats while the machines are out of step, and steady conditions of glow or darkness when the machines are in synchronism and in proper phase relation. With any number of machines connected in the same way to the same synchronizer bus bars any two can be synchronized by inserting the proper plugs. This can be done while the same transformers that feed the synchronizing lamps are simultaneously lighting the pilot lamps and at the same time any one of them may be connected to the voltmeter.

To the left of the diagram is shown the main voltmeter, which is usually supported on a swinging bracket, and the ground detecting apparatus. This voltmeter and ground detector lamp are connected across the secondary of a switchboard transformer, the primary terminals of which go respectively to the middle terminal of a two-way push button and to the center point of a four-way ground detector receptacle. This receptacle is so built that the plug which fits it may connect the center point with any one of the four points grouped around it, these four points being respectively wired to the four bus bars. By placing the plug between the center point and that connected with $A_2$, for example, and depressing the ground detector push button, the primary of the transformer is connected between bus bar $A_2$ and the ground. If $A_1$ is grounded the ground detector lamp will light and the main voltmeter will show the pressure between $A_2$ and the ground. Similarly each of the buses can be tested for grounds by revolving the plug in the ground detector receptacle from one to another of the four points.

Normally, this plug is left in the upper right hand point, which is distinguished on the switchboard by a red fibre ring. In this position one terminal of the transformer primary is connected to $B_2$, the other terminal being connected through the back contact of the push button with $B_1$. In this condition the transformer and the main voltmeter are properly connected to measure the pressure of phase B on the bus bars, which measurement may be checked at any time by means of the other voltmeter through one of the voltmeter receptacles. The ground detector lamp under this condition becomes a bus bar pilot lamp for phase B.

The dotted connections which join the secondary of this transformer through a synchronizing lamp and plug with the synchronizer bus bars are for use in case there is another source of supply of cur-

Digitized by Google

rent to the same bus bars, as from another or auxiliary station. In this case the transformer of the main voltmeter becomes a synchronizing transformer for the bus bars, so that they can be synchronized with any of the machines. When there is no auxiliary source of current this arrangement is not necessary, as one machine can be synchronized with another through their respective switchboard transformers without regard to the bus bars.

The arrangement for three-phase generators is materially different from this and is shown in Fig. 2. Here each machine is connected with the three buses through three fuses, a three-pole switch and three ammeters, one in each leg, to indicate any unbalancing of the load. From two of the terminals, A and B, of each machine between the fuses and the main switch there are tapped off two wires to the primary of a switchboard transformer. The secondary of this transformer, as before, feeds a pilot lamp and is connected to synchronizing plugs and voltmeter receptacles. One side of the secondary of each of these switchboard transformers is connected to a common bus or lead which may be distinguished on the diagram as wire No. 3, which also leads to one terminal of the secondary of another switchboard transformer shown at the right hand side of the diagram, the primary of which is connected to bus bars B and C. The other side of the secondary of this transformer is connected with wire No. 2, which runs to all the voltmeter receptacles.

The arrangement is a highly ingenious

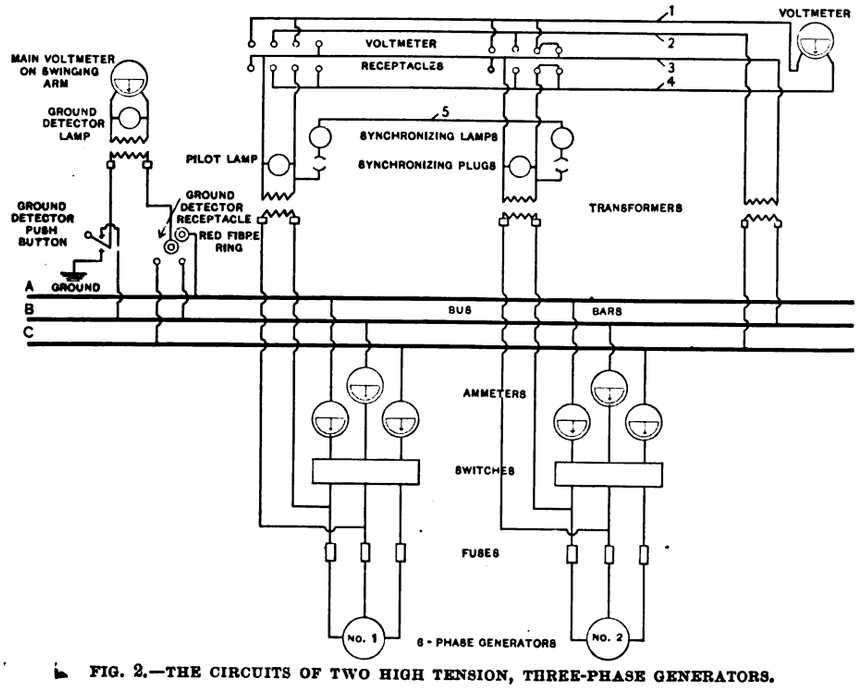

FIG. 2.—THE CIRCUITS OF TWO HIGH TENSION, THREE-PHASE GENERATORS.

one which allows the voltmeter by merely moving the voltmeter plug from one to another of the points of one receptacle, to measure the voltage across any one of the three phases. The way in which this measurement is effected is difficult to explain and must be studied out by each reader for himself. An idea of its operation may be given as follows:

When the voltmeter plug is in the right hand four sockets of the receptacle on the panel of machine No. 2 (as it is shown in the diagram) the voltmeter bus bar No. 4 is connected to the right hand terminal of the switchboard transformer of machine No. 2 and voltmeter bus bar No. 1 is connected to the common left hand terminal of all the switchboard transformers. The voltmeter therefore gets the pressure between terminals A and B of machine No. 2 whether that machine is connected to the main bus bars or not. By lifting out the voltmeter plug and inserting it in the other or left hand four sockets of the same receptacle, voltmeter bus bar No. 1 is connected with wire No. 2 and voltmeter bus bar No. 4 is connected with wire No. 3. This obviously gives to the voltmeter the pressure of the phase between bus bars B and C. By again lifting out the plug and inserting it in the middle four sockets of the same receptacle, voltmeter bus bar No. 1 is connected again with wire No. 2, but voltmeter bus bar No. 4 is connected with the right hand terminal of the switchboard transformer of machine No. 2. A little study of the connections will show that this gives a circuit through this switchboard transformer and that at the right of the diagram in series with each other. Provided that machine No. 2 is running and connected to the bus bars, this gives to the voltmeter in series two polyphase electromotive forces out of phase with each other, viz., those between bus bars A and B, and B and C. The resultant of these two component electromotive forces must, by a fundamental law of such systems, be the electromotive force of the third phase between bus bars A and C. Thus by moving the plug along between the various sockets of the 8-pointed receptacle any one of the three phases can be measured. Phase A-B of each machine can be measured while that machine is or is not running on the buses; phase B-C can only be measured upon the bus bars and phase A-C can only be measured with a machine upon the bus bars.

The synchronizing arrangement is equally ingenious. By inserting the synchronizing plugs in the panels of the machines to be synchronized a circuit is

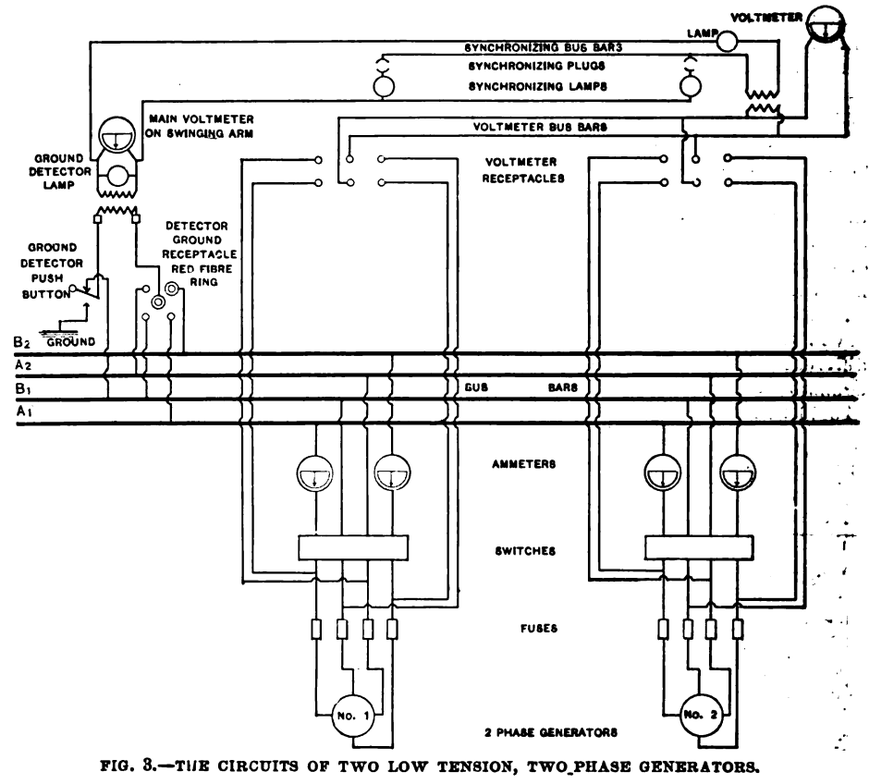

FIG. 3.—THE CIRCUITS OF TWO LOW TENSION, TWO-PHASE GENERATORS.

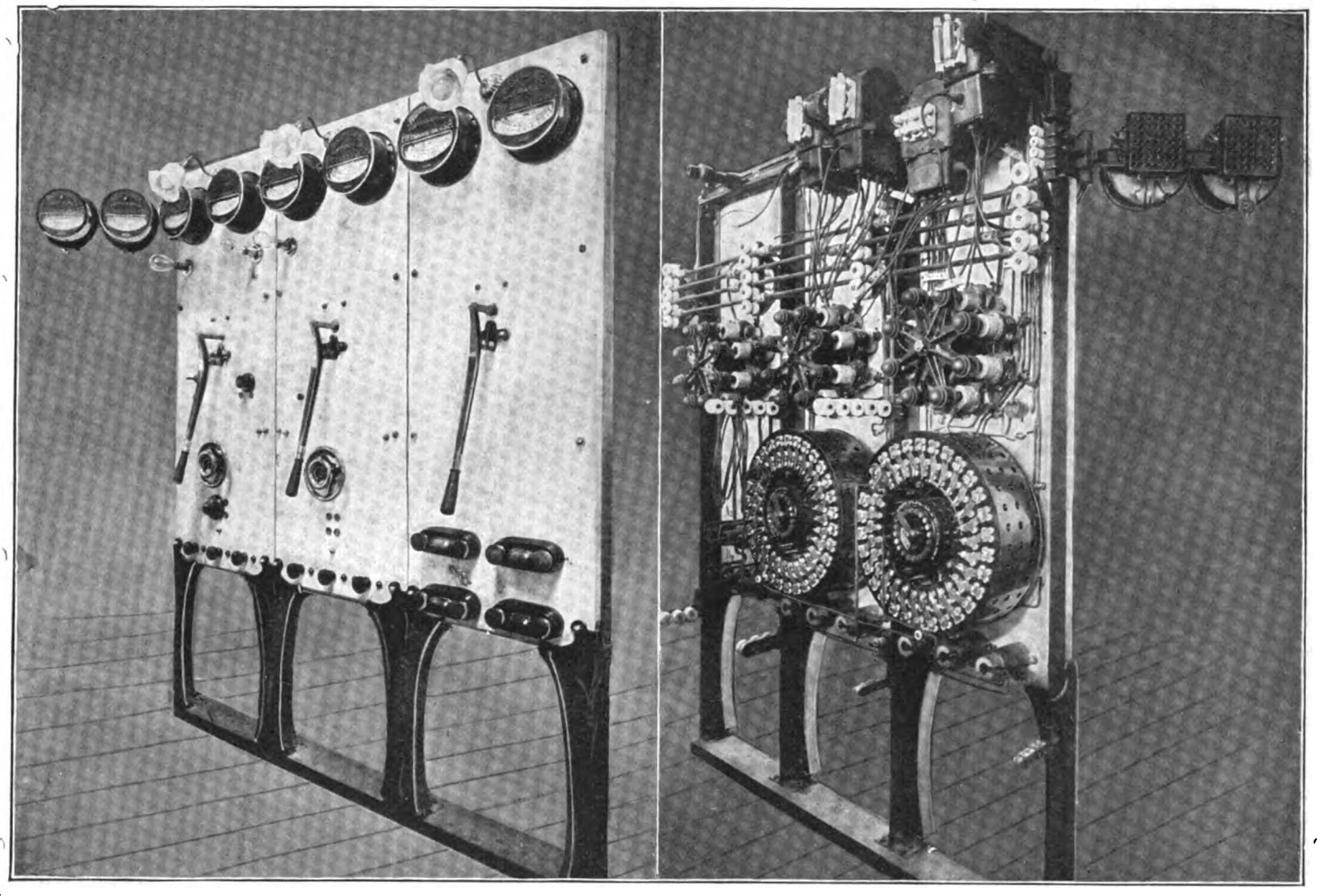
Digitized by Google

made through the secondaries of the switchboard transformers in series with each other and the synchronizing lamps and completed through wires Nos. 5 and 3, which circuit gives the proper combination of instantaneous electromotive forces to the synchronizing lamps.



To the left of the diagram appears the main voltmeter and its ground detector lamp, transformer and push button, the arrangement of these parts being exactly as in the two-phase apparatus described above. The ground detector receptacle has in this case only four points, one central and three grouped around it for connecting the transformer primary with any one of the three bus bars. Normally the plug may be left in either the upper right hand or lower left hand point, giving the main voltmeter and lamp the voltage of phases A-B or B-C, respectively.

Alternating current machines are now often built for comparatively low pressures, that is those between 75 and 440 volts. For example, rotary converters and double current generators for railway circuits have three-phase outputs at about 330 volts. Alternating current three-wire systems fed direct from machines are also coming into use. For all such cases the system of switchboard connections must necessarily differ from those given above, as the voltmeters and pilot synchronizing lamps can be electrically connected with the machine terminals or bus bars without the interposition of switchboard transformers.

Fig. 3 shows the connections for low voltage two-phase generators. Here, as before, the machines are connected to four buses, but each panel in this case contains a six-point voltmeter receptacle, the two central points going to the voltmeter bus bars, the two points at one side going to the machine terminals of phase A, and at the other side to the machine terminals of phase B. With the voltmeter plug in one position in such a receptacle the meter gets the pressure of phase A, and in the other position the pressure of phase B of the corresponding machine.

Synchronizing is done by means of transformers, although these are not really necessary on low voltage machines; there being no switchboard transformers for each machine, two special transformers are provided and fitted for synchronizing any number of machines. This is accomplished by connecting one transformer to the main bus bars and the other to the voltmeter bus bars, which latter can be plugged to any machine. The former transformer is that shown to the left and combined with ground detecting devices similar to those described above. This transformer is also connected in series with the secondary of another, shown to the right of the diagram, the primary of which is tapped off from the voltmeter bus bars. The series circuit is completed through one fixed synchronizing lamp and a synchronizing plug and lamp on each machine panel. Obviously there is no need of plugging in a different lamp for each machine synchronized, but in order to bring the synchronizing signal on the panel of the machine to be synchronized the plug arrangement is used.

The arrangement for low voltage three-phase machines is shown in Fig. 6, page 512. Here but one switchboard transformer is used, the synchronizing being done entirely without transformers. The machines are connected, as usual, through fuses, switches and ammeters to the bus bars, and each leg of each machine is connected to the points of a voltmeter receptable, to which also run branches from the voltmeter bus bars. By inserting a four-point plug in the right hand four points of this receptacle the voltmeter is connected directly across one phase of the generator, the middle four points giving another phase and the left hand four points giving the third phase. The other receptacles similarly serve for the other machines. Thus each phase of each machine can be measured entirely independently of the bus bars.

FIGS. 4 AND 5.—FRONT AND REAR VIEWS OF A HIGH TENSION, TWO-PHASE BOARD, WITH TWO GENERATOR AND ONE LOAD PANELS, SHOWING THE APPEARANCE AND ARRANGEMENT OF THE DEVICES INDICATED IN THE DIAGRAM FIG. 1. FIG. 5 SHOWS ALSO THE CONCENTRIC MAIN AND EXCITER RHEOSTATS, THE PLUNGER-TYPE SWITCHES AND THE METHOD OF SUPPORTING THE BUS-BARS AND TRANSFORMERS.

Digitized by Google

Two wires are carried the full length of the machine panels for synchronizing purposes, and one of these is connected with leg C of each machine through 4 lamps in series with each other, one on the front of the panel and three behind it. The other synchronizing bus is connected to leg A of each machine through a plug receptacle. By inserting two plugs respectively on the panels of the two machines to be synchronized a circuit is made through phase A-C of the two machines in series with each other and the 8 lamps. The machines being wound for 440 volts, the electromotive force in this circuit beats between 880 volts and zero when the machines are out of synchronism, and therefore illuminates and extinguishes the 8 lamps in series with each other until the machines are brought together. For lower voltages fewer lamps would be used. For instance, with 330-volt machines but three lamps in series for each synchronizing connection would be necessary.

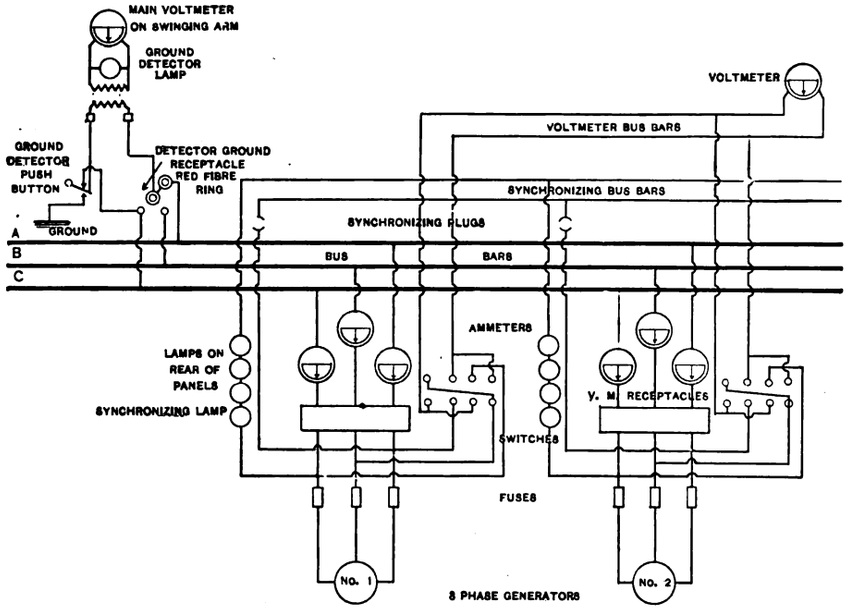


FIG. 6.—THE CIRCUITS OF TWO 440-VOLT, THREE-PHASE MACHINES.

The appearance and arrangement of the instruments on the boards are shown by Figs. 4 and 5, illustrating respectively the front and back of a two-phase, high tension board, containing two machine and one load or feeder panels. The two voltmeters are mounted on a swinging arm so that their indications may be read from any position in front of the board. The main switches are of the plunger type, with no live parts exposed on the front of the board. The two machine panels, as Fig. 5 shows, contain below all other instruments three plugs each. These are for the field circuit, to connect either one of the two exciters, and are capable of breaking the field current. Immediately above these are the voltmeter plug receptacles, that on the left hand panel being 6 point and holding, at the time the illustration was taken, the plug in the left hand 4 points. Above these are the rheostat handles, the exciter rheostats being concentric with the main rheostat and operated by concentric hand wheels. Above and to the right of the hand wheels on the left hand panel is the ground detector plug, this panel containing also one ground detector lamp in addition to the synchronizing lamp and the bracketed pilot lamp. The ground detector push button also appears on the front of the board. The right hand panel contains simply two ammeters, one in each phase, a main plunger type switch and four lignum vitae fuse blocks, one in each leg of the two-phase system.

## A COMBINED TROLLEY AND STORAGE BATTERY LOCOMOTIVE FOR MINES.*

The numerous accidents to mules coming in contact with overhead trolley wires in mines have raised a demand for some sort of a system whereby the animal will become an unnecessary evil in the operation of a mine. To construct a bonded track and stretch a trolley wire to the face of all workings would be too expensive for general mine practice, and, in consequence, it is the custom in some mines to use a small mine wagon and have the miner push it to and fro from face to parting, from which place it is taken with the locomotive. In order to eliminate the mule from the mine and haul from the face of all workings, a combined storage and trolley locomotive has been devised, whereby the heavy work on headings is done from trolley, and while so running the attached battery, which is carried in circuit, absorbs sufficient current to do the necessary room work. Such a locomotive, the only one of its class, was built by the Baldwin-Westinghouse combination for the Southwest Virginia Improvement Company, having the following dimensions:

| | |
|---|---|
| Gauge | 36 inches |
| Width over all | 42 " |
| Height, including battery box | 44 " |
| Length | 124 " |
| Weight, including battery | 9,000 lbs. |
| Electric equipment | 2 10-h. p. motors |
| Rheostatic controller. | |

This locomotive was designed to haul on the level one loaded car weighing 9,000 pounds on storage, and was accordingly equipped with 90 5-D. cells, and having mounted therewith a special battery circuit breaker, etc.

After the locomotive was built the mine manager changed his plans and concluded to try it in a part of the mine where the battery would be required to handle loaded cars up a 4 per cent. grade and empties up 8 per cent. In addition, the trolley line was an extension of the feed line for some ten or twelve mining machines, in consequence of which the voltage varied from 110 to 200 and the battery would either feed back into the line or throw the circuit breaker. In order to prevent the latter it was so adjusted that it would not fly out, and the battery was virtually short circuited a large number of times each day without any bad effect. With this condition of affairs it was impossible to hold sufficient current in the battery to do the desired amount of room work, and it became necessary to stop a total of about thirty minutes each day for renewals. It must be remembered that this work was under the supervision of a mine foreman unacquainted with storage batteries. Having gone to such extremes in the use of this locomotive it was suggested that a new and independent feed line would be a great improvement; it was installed, with marvelous results. The voltage became constant, and, the battery often discharged for a short time at three times its rated capacity; yet the work has been ideal, and after almost three months' service there is no appreciable wear on the battery. It produces a tractive effort up to the point of adhesion of the locomotive when working on storage, and the regular work is to take seventeen empties weighing 60,000 pounds, including locomotive, from side track up a short 1 per cent. grade, then down a 4 per cent. to a level, from which place it starts to distribute in rooms having a maximum of 8 per cent. in favor of loads. After distribution it proceeds to collect the loads in trips of two cars each, on account of the 4 per cent. grade against loads on heading, and deliver them to the side track while working on trolley. In this manner this one locomotive is capable of delivering to this side track, over an average round-trip haul of 4,000 feet, 200 loaded wagons daily direct from face of working, which is the work, under existing conditions, of 12 mules and 8 drivers. It is the intention to place a night force, and if sufficiently large, the saving will be the care of 24 mules and time of 12 men, or an amount equal to $8,000 annually.

This same company has placed an order for six more of the same class of

*Extract from paper read by Harry K. Myers before the Engineers' Club of Philadelphia.

Digitized by Google

locomotives, and is considering the matter of constructing heavier ones of the same kind to take the place of steam locomotives now in use, but which are very injurious to both the ventilation of the mine and the timber work.

## Among our Foreign Contemporaries

**The Seasoning of Wood with the Aid of Electricity.**— In the treatment of wood by usual methods, with either preservative or fire-proofing compounds, the wood must first be thoroughly kiln dried, after which the compound must be forced in under high pressure and temperature, and even then the penetration is not very deep. M. Nodon-Bretonneau has developed a means of accomplishing this result more thoroughly and rapidly by the use of electric currents, which seem to cause a sort of endosmotic carriage of the treating liquids into the fibers of the wood. The arrangement of an extensive plant for this purpose was recently described in "La Nature," from which the following description and the illustration, Fig. 1, have been taken. The treatment is carried out in a large wooden vat, the bottom of which is lead-lined and connected with the positive terminal of a direct-current dynamo. The wood is piled criss-cross, within the vat, upon a supporting framework with a false bottom, which is maintained at any desired elevation by means of hydraulic jacks, acting upwardly through the bottom of the vats. On top of the upper layer of wood there is lowered a large tray with a felt bottom and an extended sheet electrode, which is connected with the negative terminal of the dynamo. The vat is filled up to the level of the wood, but not up to the level of the upper tray, with the solution with which it is desired to replace the sap of the wood, the solution being either a preservative or fire-proofing material, according to the purpose of the treatment. In the works at Aubervilliers, which are shown in the illustration, the solution is a neutral bororesinate of sodium. The application of the current causes an endosmotic action which carries the solution upwardly through the wood, driving out the sap ahead of it.

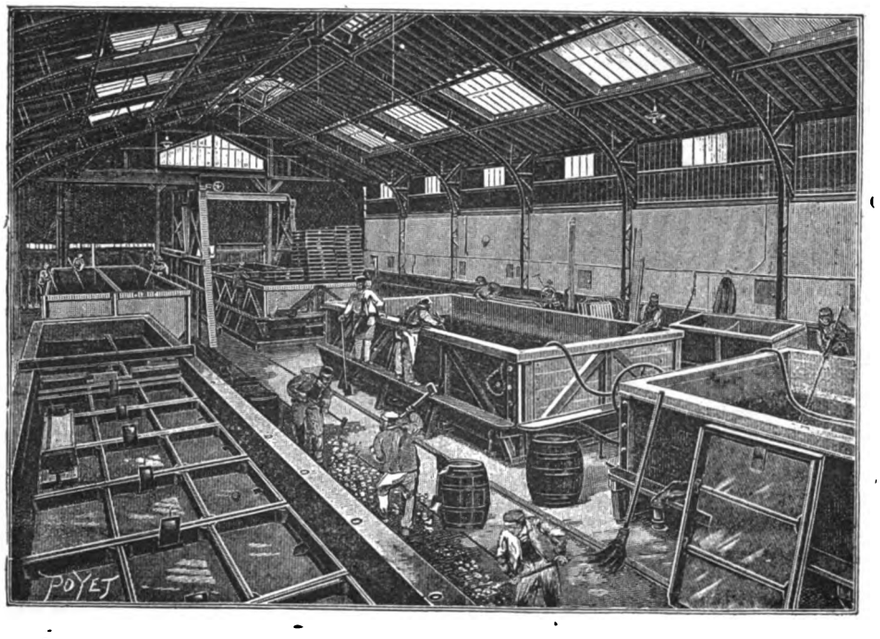

FIG. 1.—A FRENCH PLANT FOR THE ELECTRICAL TREATMENT OF WOOD WITH PRESERVATIVE OR FIREPROOFING COMPOUNDS.

**The Hartman-Braun Hot Wire Instruments.**—Owing to the fact that an English manufacturer has obtained the rights to manufacture and sell voltmeters and ammeters of the type covered by the Hartman-Braun patents, the English papers have been giving descriptions of these instruments which may be of interest also to American engineers since the same type was taken up here by the Stanley Electric & Manufacturing Company shortly before its consolidation with the Sprague Company. The instruments involve several interesting peculiarities which improve their operation over that of previous types and the method of adapting the hot wire principle to ammeter use is also interesting. Fig. 2 shows a general outline of the parts and their connections. The hot wire proper, shown at A A, is made of platinum silver about 6 or 7 ins. long, stretched between two terminals, T′ and T″, until it is almost taut. Near the center of this wire there is attached another wire of phosphor bronze, B B, running to a third terminal, T‴, at the lower part of the instrument. Branching from this phosphor-bronze wire is a cocoon fiber, C, which is looped around the jewel mounted steel spindle carrying the needle, and terminates in the spring, S, which maintains it taut. The whole arrangement of the fiber and wires is thus subjected to tension and any slacking or sag of the hot wire at the top is immediately taken up by the steel spring and transmitted by the motion of the cocoon fiber to the pointer. As is well known, when a wire is stretched nearly straight between two points the slightest change of its length causes a great change in the amount of slack. The arrangement of the platinum silver and the phosphor-bronze wires thus obtains a double multiplication of the deflection in this way, a third multiplication being given by the ratio of the length of the pointer to the diameter of the small spindle on which the cocoon fiber is coiled. Thus a very slight change in length of the wire, A A, causes a considerable movement of the pointer. In addition the ratio of the change of sag to the change of length becomes greater as the wire becomes straighter; thus the scale becomes more open at the higher readings. The whole of the hot wire movement is mounted on a metal compensation plate made from an alloy whose temperature coefficient is the same as that of the measuring wire. To deflect the pointer of the voltmeter over the full scale a current of .2 ampere is required. For voltmeter work a series resistance or multiplier of constantin is connected in series with the hot wire. For ammeter work the hot wire is tapped at several points by thin silver foil strips which divide it into sections, these sections being placed in parallel with each other. By this means four or five amperes may be sent through the wire with a drop of potential not exceeding ¼ volt (the ammeter hot wire being thicker than the voltmeter hot wire). For higher currents a constantin shunt is used. A magnetic damping arrangement is provided to prevent oscillations.

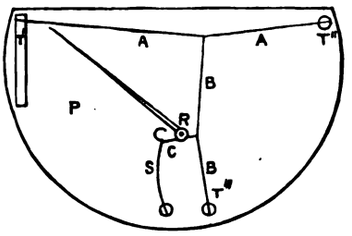

FIG. 2.—THE ARRANGEMENT OF THE HOT WIRE AND DEFLECTION MULTIPLYING APPARATUS OF THE HARTMANN-BRAUN INSTRUMENTS.

**A System of Train Lighting.**—When axle driven generators are used in connection with storage batteries for lighting cars or trains on steam railways some means must be provided for reversing the connections of the armature when the motion of the train is reversed, for discon-

Digitized by Google

necting the generator when the speed becomes so low that it cannot maintain voltage, and for preventing the generator from delivering too high a voltage when the train runs very rapidly. For the last purpose two general plans have been developed by two different companies in this country. One is the use of a belt applied with a definite tension such that when the output of the generator becomes greater than a certain amount the belt will slip. The other consists of an automatically operated field rheostat. Still a third means of accomplishing the same result used upon cars now in service on the Paris, Lyons & Mediterranean Railway system was recently described in the "Revue Generale des Chemins de Fer." In this system the current from the generator to the storage battery and lamps passes through a series-wound motor on the shaft of which is a friction brake set up with a certain definite pressure. When the current flowing is small this motor does not turn, but when the current exceeds a certain definite strength, in this case 28 amperes, just sufficient to overcome the friction of the brake, the armature of the

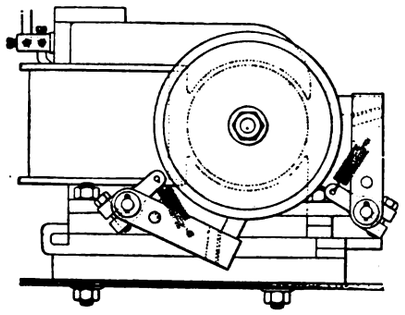

FIG. 8.—THE AUTOMATIC VOLTAGE GOVERNOR OF A SYSTEM OF AXLE DRIVEN GENERATORS.

motor begins to revolve. In case the train speed increases and with it the pressure of the generating dynamo, tending to increase the current delivered from the dynamo, the speed of the motor increases, keeping down the e.m.f impressed upon the storage battery and lighting circuit to a constant value, the back e.m.f. of the motor increasing automatically and just taking up the difference between the impressed e.m.f. of the generator and the proper e.m.f. which should be delivered to the storage battery. The regulating motor is illustrated in Fig. 2. The brake pulley is of bronze and the blocks which are pressed against it are of what would be considered in this country a very unusual material for this purpose, viz., carbon. This material was probably adopted to give a friction of rest more nearly equal to that when running than can be obtained with most materials.

---

**Improved Joint for Conduit Systems.**—Mr. J. D. F. Andrews in "The Electrical Review," London, points out the well-known disadvantages of soldered joints insulated with rubber or rubber compounds, in conduit systems, and proposes the using of porcelain as insulation. The article describes and illustrates several fittings designed for this material. Fig. 4 shows a junction box where a 2-conductor wire is spliced. The two wires to be joined are bent upwardly and their ends are wrapped with fine copper wire and

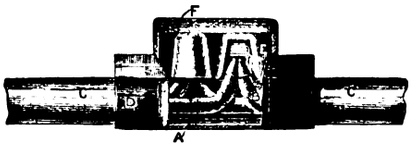

FIG. 4.—CONDUIT JOINT INSULATED WITH PORCELAIN.

soldered. Over this upward bend there is then placed a porcelain thimble, E. The metal cover, F, fastened by screws, encloses the whole, and may be made water tight by soldering or the use of red lead.

---

**A Wireless Telegraph Patent.**—"The Electrician" of London describes some patents recently issued by the British Patent Office to Mr. Marconi. One of these claims an interesting improvement in Hertz wave working which consists of the use of an induction coil or transformer between the circuit of the vertical wire and the coherer. The purpose of this transformer is to raise the pressure of the oscillations sent in to the coherer, the low tension coil of the transformer being connected in the vertical receiving wire and the high tension coil in the coherer circuit. The arrangement is designed to make use of the discovery that the effect of electrical oscillations on a coherer seems to increase very greatly with their e. m. f., but not to be affected particularly by their current strength. This is due probably to the fact that the oscillations cause in the imperfect contacts of the coherer a local breaking down of the resisting films between the particles, and this breaking down is greater with increased e. m. f. The arrangement of the circuit is shown in Fig. 5, where c is the primary of the transformer inserted in the wire which, at b, leads to ground, and

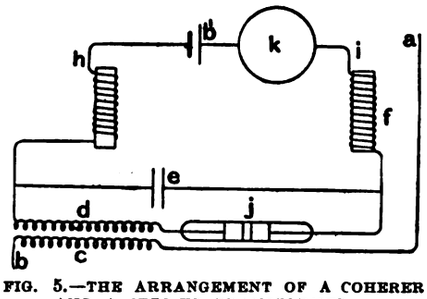

FIG. 5.—THE ARRANGEMENT OF A COHERER AND A STEP-UP TRANSFORMER.

at a leads to the overhead sphere. The secondary of the transformer is shown at d, in series with the coherer, j, and a secondary circuit for the oscillations is closed by the condenser, e; k is the indicator or relay connected in series with the battery and the coherer through the choke coils, f and h.

**Pollak-Virag High Speed Telegraphy.**—Interesting experiments with the Pollak-Virag system of telegraphy have recently been made between Budapest and Vienna, a speed of from 1300 to 1500 words per minute being obtained. A description of the apparatus recently appeared in "The Electrician" of London, from which the following points are abstracted. The transmission is accomplished by the ordinary strip of perforated paper, similar to that of the Wheatstone automatic, and a rather crude arrangement of contact brushes acting through the perforations. The main element of interest lies in the receiver, which consists of a coil acting upon a diaphragm like that of a telephone, this diaphragm actuating a small mirror which reflects light upon a photographically sensitive strip of paper. The arrangement of these parts is shown in Fig. 6, where the coil appears at the right actuating a diaphragm to the left of it. The small concave mirror of steel is made to oscillate through considerable angles for small vibrations of the diaphragm by pivoting it against a knife edge, forming one pole of a permanent magnet, the other pole of which ends in a weak spring at-

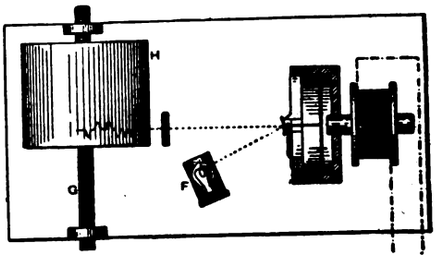

FIG. 6.—DIAGRAM ILLUSTRATING RECEIVING APPARATUS OF POLLAK-VIRAG TELEGRAPHY.

tached to the diaphragm. The steel mirror is held magnetically against the knife edge and the spring and the vibrations of the latter cause oscillations of the mirror about the knife edge as a pivot. This causes oscillations of the beam of light from an incandescent lamp, F, when reflected through a converging lens on to the sensitive paper, which is mounted on a drum, H. The drum is kept in motion so that the oscillations cause waves in the line traced by the beam of light. The drum is also carried axially a certain distance during each rotation by means of a screw thread on its spindle, so that many lines of the record can be obtained on one sheet. The electrical qualities of the telegraph line are improved for high speed work by shunting the receiving magnet with a condenser and the transmitting instrument with an inductive coil.

---

**A Repeater for Wireless Telegraphy.**—To increase the range of wireless telegraphy an Italian, M. Guarini-Foresio, has designed an automatic repeater which was recently described in "L'Electricien." This repeater is so designed that when electric radiations from a distant station are intercepted by its vertical wire, setting up an action in its coherer, this coherer

Digitized by Google

closes a relay circuit, which in turn excites the induction coil, sending out fresh waves from the same vertical wire and overhead sphere. Naturally the vertical wire must be instantly disconnected from the coherer when the induction coil is excited, and this is done automatically by means of another relay, the coils of which are placed in parallel with the primary of the induction coil. Whenever the induction coil is excited the armature of this relay is attracted, cutting off the coherer. The device appears to be practicable for repeating short impulses such as dots, but obviously would not work with the ordinary Morse code using dashes, since prolonged impulses coming through it would set in action its induction coil and thereby cut off the vertical wire from the coherer before the dash could be completed, thus repeating the prolonged impulses in a broken form.

**The Wehnelt Interrupter.**—The German papers have recently contained advertisements of a commercial form of the Wehnelt interrupter, made by Siemens & Halske. The appearance of this instrument is shown in Fig. 7. The platinum wire anode passes down through a vulcanite tube, the lower end of which ends in a porcelain cap through which the wire

FIG. 7.—A GERMAN FORM OF THE WEHNELT INTERRUPTER.

projects. The length of the projection can be adjusted by a thumb screw at the top. The cathode and anode are lowered into a square receptacle shown at one side of the illustration, this receptacle having attached to it a coiled tube for circulation of the electrolyte in a cooling bath contained in a larger enclosing chamber.

**A Novel Electro-Magnetic Brake.**—In a recent lecture on "Car Brakes," before the German "Electrotechnische Verein," Max Schiemann described what he termed with true German definiteness an "adhesion multiplying electro-magnetic rail brake combined with wheel shoe brake." This device consists of a number of magnets designed to exert their attraction upon the rail head to which they bind themselves, causing friction which checks the speed of the car. The general arrangement of the parts is shown in Fig. 8. The magnets consist of coils closed in a cylindrical metallic cover and alternately magnetizing north and south pole pieces, which project downward toward the rail head. The whole arrangement is flexibly supported and in the combination shown in the illustration is counterweighted, so that normally it rises away from the rail. When energized the magnet draws itself down to the rail and binds against it, the friction carrying it backward and under the rear wheel, a shoe attached to the magnetic device wedging itself under the wheel and thereby increasing the retarding effect. The magnet is preferably energized by current from the car motors acting as generators so that as the car approaches standstill the braking action is released and a jerky stop is avoided.

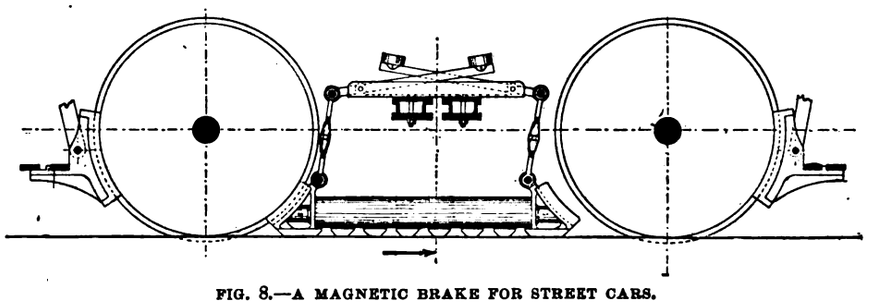

FIG. 8.—A MAGNETIC BRAKE FOR STREET CARS.

**Friction Losses in Dynamos.**—In several of the simplest methods of determining the efficiency of dynamos, it is very desirable to know the friction losses; these losses are also the ones which are more likely to change in the course of time, when the dynamo is in use; the laws concerning these friction losses and the determinations of their value are therefore of practical interest. A somewhat prolonged discussion concerning these losses has been continued in a number of issues of the "Elektrotechnische Zeitschrift," and one of the results has been a long article by Mr. Dettmar in which he goes into this subject very thoroughly and develops some points of practical value. One of the chief points which he brings out is that the loss of work due to friction is not proportional to the speed, as is often supposed, but that it increases quite appreciably with the speed; by this he refers to the sum of the various friction losses in the dynamo. This variation from a straight line law has been attributed to the air friction, but he shows that this is not correct, and that it is the coefficient of friction which is variable. There are three methods by which the friction may be measured, first by means of a calibrated motor, that is, driving the dynamo to be measured by means of a motor whose efficiency has been accurately determined. This method is not a good one if the motor drives through a belt, as that involves an unknown quantity in the form of the power absorbed by the belt; but if the machine is directly coupled, the method is a good one, but is limited; the calibrated motor, for instance, should not be heavily loaded by the machine which it drives; the method has advantages when no convenient source of current is obtainable for the other methods. The second method is the well known one of running the machine as a motor, unloaded, and has already been described; it combines great accuracy with relative simplicity. The third method consists in bringing the dynamo up to the proper speed either mechanically or electrically, and then letting it run down without doing any work other than overcoming the friction losses. The application of this method is, however, limited for absolute determinations, as it involves a knowledge of the moment of inertia, etc.; it is very serviceable, however, for determining relative values, that is, for comparing the losses at one time with those at another; moreover, the time required for making such a test is extremely short and this is of great value, as the other conditions, such as temperature, are not so likely to change during the test. If the losses are determined absolutely once for all, then the method serves very well for determining the condition of the bearings; moreover by observing the action of the machine during the last turn before it stops, indications will be obtained as to the balancing of the armature. Sometimes the combination of two of these methods is of use, as, for instance, by using the first or second in order to find the absolute values of the relative ones given by the third method. In the third method, which he calls the "running down" method, a tachometer (this is an instrument for indicating the speed at any moment) must not be used, as that absorbs considerable power; in place of it the remnant magnetism may be used in connection with a voltmeter. The speed is measured once for all while running, and also the voltage at that speed due to the remnant magnetism; then the voltage readings may thereafter be used as a measure of the speed, correcting it of course by the factor thus determined. Otherwise a revolution counter, like a bicycle cyclometer, could be used. From this very lengthy series of tests he draws the following conclusions: At a constant temperature of the bearings and a constant specific pressure (that is, a constant pressure per square inch) the friction coefficient, and therefore the loss of the work by friction, increases as the 1.5th power of the speed. The nature of the oil used does not change this law but merely affects the absolute values. The values for this exponent, which he found for a very large number of tests, varied between 1.3 and 1.55, the smaller one being for a smaller machine and the larger one for those of larger sizes.

## THE STREET RAILWAY CONVENTION.

The annual convention of the American Street Railway Association was held this year in Chicago, on Tuesday, Wednesday, Thursday and Friday, October 17th to 20th inclusive. The convention headquarters and exhibit hall were at Tattersall's, a location well suited to the needs of the Association.

The number of papers to be read before the Association was, this year, unusually small in order to give ample time for discussion. The papers on the program numbered five, and but four of these were read. Another unusual fact about the papers is that none of them was upon an electrical subject. Following the custom set last year, the last day of the convention was specially set aside for the purpose of visiting the exhibits.

The entertaining and social features of the convention consisted of a reception in the parlors of the Auditorium Hotel Tuesday evening, a trip to the drainage canal Wednesday afternoon, a trolley ride to the Union Stock Yards Thursday afternoon, a theatre party Thursday evening, a trip to the power house of the South Side Elevated Railroad Friday afternoon and the usual annual banquet Friday evening.

### THE PROCEEDINGS OF THE FIRST DAY.

The convention opened Tuesday morning with the usual smooth running characteristics of the Street Railway Association, the meeting being called to order by President Sergeant. After an address of welcome by a representative of the Chicago city government, the President made his annual address, a portion of which abstracted herewith may be of interest to the reader of these columns.

### PRESIDENT'S ADDRESS.

Gentlemen of the American Street Railway Association: We are to-day assembled for the eighteenth annual gathering of our Association, and for the second time we meet in this great and prosperous city.

Those gentlemen who met here in Chicago in 1883, many of whom are, I trust, present today, could have had little conception of the changes in their business which were to occur before the end of this century. At that time there were in Chicago street railways operating about 153 miles of single track. At the present time the mileage of the surface street railways of this city is about 736 miles, of the Chicago interurban street railways about 261 miles, and of the elevated street railroads about 100 miles, either operated or under construction, making an increase since your last meeting here of 944 miles of track. This remarkable extension of street railways, their equipment with mechanical motive power, the unique union loop system, and the successful application of electric power in the elevated railway service, are not only a wonderful testimonial to the courage, energy and capacity of their projectors, but they have made Chicago a street railway Mecca to which we all may come to observe and learn. We are, therefore, to be greatly congratulated upon the advantages afforded us by the selection of this city for our convention.

The year which has passed since we met has presented some unusual features, which are worthy of our attention. The tendency towards consolidation of small or competing roads into larger homogeneous systems has been manifested by many examples. With the introduction of electric motive power the old-time horse railway company, operating a few miles of track on two or three city streets, has disappeared, and its larger successor has found necessary such changes in administration, such extensions of its system and service, that the advantages of combination with rivals have become more and more manifest. The street railway which formerly gave a short distance urban service has found itself extended far into the country; the same car which disputes the passage of a busy city street with a truculent teamster, may, an hour later, be flushing partridges and grouse along the rural highway, stopping to leave the tired artisan at his country home, and bringing a healthful excursion within reach of the humblest family; thus the trolley car is rapidly filling a long felt want, which was neither within the power nor the disposition of the great steam railroads to supply. All this means changed conditions with new responsibilities, and emphasizes the need of consolidation.

To successfully amalgamate such properties and organize and operate them with due economy and a just regard for the needs of the communities to be served, requires of the operating officials a high degree of experience and skill. The new problems to be met offer better positions to which those who are ambitious may aspire, and the wonderful rapidity with which this situation has been developed, will be a lasting monument to the officials of our American street railways. The advantages of this larger growth are many and perhaps not the least is a growing respect for the value and importance of the street railway industry, which we may all hope will ere long be recognized by just laws which shall deal fairly and equitably with the relations of the street railways to the municipalities, and give to capital invested in urban and suburban transportation, security and a fair return upon the investment.

### REPORT OF THE SECRETARY AND TREASURER.

The statement of the finances of the Association showed cash on hand Aug. 25, 1898, as $3,656.28, and the receipts to Oct. 11, 1899, as $7,650.87, of which $450 was for membership fees, $3,930.67 for dues, $3,137.70 for space at the Boston convention and $132.50 for space at the Chicago convention. The total expenses to Oct. 11, 1899, were $5,648.28, leaving a balance of $5,658.87.

Aug. 25, 1898, there were 173 members; to Oct. 11, 1899, 7 new members had joined and 8 had withdrawn, making the membership at that date 172.

### MR. YERKES' PAPER.

The only paper of Tuesday's proceedings was one entitled "Investments in Street Railways; How Can They Be Made Secure and Remunerative?" which was read by Charles T. Yerkes, President of the Chicago Consolidated Traction Company and of the Union Elevated Railroad Company. Mr. Yerkes traced the history of the development of street railways from the day of the bob-tailed one-horse car on the strap-rail single track to the present day of many-tonned luxurious double-truck electric cars on road beds comparable in weight and strength with the foundations of fair sized buildings. Mr. Yerkes' chief argument was for a more settled policy on the part of municipalities toward the street railway corporations and offered suggestions for a solution of this problem fair to both sides. To quote from the paper: "Every State wherein there are large cities, which necessarily have important street railways, should have a commission appointed to ascertain the condition and requirements of this industry. The commission should be appointed by the Governor of the State and should be composed of intelligent business men of first class standing who are not interested in street railways. Under no condition should a person holding office, or who is ambitious to do so, be named. A man of this character is never to be trusted in any affair where courageous opinions are expected. The reports of such a committee should have great weight with the legislators.

"I believe that all corporations which receive their life from the commonwealth should be subservient to that commonwealth. That there is nothing in their formation or general business which should not be reported to the proper authorities and be subject to investigation. I believe that the law should provide that an intelligent commission be appointed by the Governor of the State in the same manner as is now done in this State, in regard to the commissioners of the park system. The duties of this commission would be to see that the laws concerning street railways are carried out and that the companies have the protection to which they are by law entitled. The commissioners should have terms of 15 years, so as to insure their becoming experts, and receive such salaries as would enable them to live well and take care of their families in a good manner. They should understand, when appointed, something of the street railway business, and as the years pass by their knowledge should increase, as also their worth. They should have the power to dictate to the railway companies where new roads should be laid, if at all, and also the kind of new improvements to be used when a railroad contemplated making any change in motive power. They should have the power to regulate the devices to be used for saving life and preventing accidents. With an intelligent, honest commission of that kind street railway managers would be made more comfortable, the people would

Digitized by Google

be benefited and the securities of the corporation would be more solid. The advice of the commissioners would be sought, and the advice of such men, with the experience and knowledge they would naturally have, would be most valuable to any railway manager. Their reports would be explanatory, and much of the ignorance regarding street railways which is fostered by our enemies, particularly in this part of the country, would be done away with."

In the discussion which followed Col. N. H. Heft made a statement that is of interest to engineers, as follows: "While I believe that it is necessary to look after your municipalities, your Legislature and your representatives in general, yet I believe that the greatest benefits that will come to the street railway investment will be through the mechanical and electrical engineers in improving the present equipment of the railroad. I believe that our attention has never been sufficiently called to this matter, and that in a great many cases we have suffered from this lack of attention to the question of car equipment and to the weights that we are hauling to-day. We haul one passenger for whom we receive five cents, and for whom we are compelled to stop our cars twice, to take him on and to let him off. In going over the question of weights that we are drawing to-day, I was simply horrified to find that for every passenger we were hauling 720 pounds of dead weight, where the steam railroads are hauling 137 pounds with their standard system of railroad equipment. Now, I think that it behooves the street railroad managers to turn their attention to the question of equipment to see if we cannot get rid of some of this weight, and we expect to produce within the next two months a car, including the entire equipment, that will not exceed 227 pounds per passenger."

Wednesday morning a paper was read by Mr. J. H. Vanderveer, Superintendent of the shops of the Brooklyn Rapid Transit Company, on the "Care of Car Equipment," part of which read as follows:

"In the maintenance of motor equipments to-day, where almost continuous service is demanded and high mileage made, only those equipments fitted with both oil and grease boxes will safely run over 40 days without a thorough overhauling. To do this overhauling a large road will be obliged to do it at a number of different points. To overhaul a motor car thoroughly it is advisable to have at each overhauling shop extra trucks with motors mounted and all in first class order ready to run under a car body whose trucks and motors need overhauling. To properly lift the body from the trucks four duplex chain hoists, or air hoists, conveniently located, together with two cross timbers and four stirrup irons, form as good a combination as can be found, and will do the work with the least possible injury to the car body. When the body is lifted the truck to be overhauled is run out and the good truck substituted, the car lowered, connected up and turned over to the operating department. The whole operation taking about one hour, and for that length of time only is the use of the car body lost. For convenience in overhauling, a suitable crane, properly located, equipped with a carriage and another duplex or air hoist, will be found of great convenience. Such a crane can be readily made in any blacksmith shop and for the arm a piece of old rail can be used. When the motor is opened the armature should be lifted out and placed on a suitable rack, where the commutator can be cleaned and the armature tested for insulation. The fields should also be tested for drop, and where there is a drop those fields and armatures should be used in motors by themselves, keeping new and rewound fields and armatures in motors by themselves. This prolongs the life of the equipment and reduces the number of crippled cars taken off the road. The motor shell should be thoroughly cleaned out, either by compressed air or by washing with kerosene. The grease in the grease boxes should be taken out and put in a gear case and the grease boxes thoroughly washed out with kerosene. Brush holders should be taken out and thoroughly inspected and cleaned. At the same time is the best opportunity for truck inspection. The writer has found that all overhauling done with the car standing over the pits, the bottom half of motor dropped, does not allow the thorough overhauling necessary to keep the motor equipment in the shape it should be kept, besides tying up a complete equipment while such overhauling is being done."

At the meeting on Thursday a paper was read by Mr. Edward Butts, Chief Engineer of the Metropolitan Street Railway Company of Kansas City, Missouri, on the "Construction and Maintenance of Street Railway Tracks." The paper was not, as its title indicates, a general description of this subject, but described in detail one style of truck construction in which the rails are bedded in heavy concrete stringers and the joints are cast-welded. Following the discussion on this paper the report of the nominating committee was read. The committee recommended Kansas City as the next place of meeting and the following gentlemen for officers of the Association for the ensuing year:

President—John M. Roche, General Manager Chicago Union Traction Company, Chicago, Ill.

First Vice-President—John A. Riggs, President United Traction Company, Reading, Pa.

Second Vice-President—H. H. Vreeland, President Metropolitan Street Railway Company, New York City.

Third Vice-President—F. G. Jones, Vice-President Memphis Street Railway Company, Memphis, Tenn.

Secretary and Treasurer—T. C. Penington, Treasurer Chicago City Railway Company, Chicago, Ill.

Executive Committee—The President, the Vice-Presidents and C. S. Sergeant, Second Vice-President Boston Elevated Railway Company; C. K. Durbin, General Superintendent Denver Consolidated Tramway Company; Nicholas S. Hill, Jr., General Manager Charleston Consolidated Gas & Electric Company; Charles W. Wasson, Vice-President Akron, Bedford & Cleveland Railroad Company; John R. Graham, President Quincy & Boston Street Railway Company.

After the election of these officers a paper was read by Mr. Ira A. McCormack, General Superintendent of the Brooklyn Heights Railroad Company on "Train Service and Its Practical Application," a subject not of particular interest to the majority of readers of this paper.

Over 300 members of the Association and friends attended the banquet in the auditorium. The toastmaster of the evening was C. S. Sergeant, the retiring president. One feature of the banquet was the installation of the new officers.

## THE LINE LOSSES OF POLYPHASE TRANSMISSION.

BY GEORGE T. HANCHETT.

At various irregular intervals there appear in the columns of the technical press and elsewhere tables of the relative amounts of copper required by different systems for the transmission of equal amounts of power over a given distance at equal voltage and with equal economy.

The tables advanced by conceded authorities differ widely and are hence very confusing to the student who happens to notice the disparity, and in the absence of definite information as to how the results are obtained he is likely to charge one or the other of his sources of information with a blunder or to conclude that the necessary copper to transmit polyphase power is a mysterious variable, to be classed in the same category as the impedance and the power factor of circuits and capable only of approximate prediction.

As a matter of fact the necessary copper for a polyphase transmission is capable of just as accurate calculation as parallel cases in direct currents, and the only reason that authorities differ is because they consider the problem from different points of view. As will be seen later in this article, equal voltage, an unquestionably definite expression in the case of direct and single-phase alternating transmission, may in polyphase transmission refer to one of several voltages, all of which exist in the same line. For instance, we may compare the single-phase system with the Y connected three-phase system shown in Fig. 1, the common junction being connected to earth, as is frequently done for purposes of regulation.

If we compute the necessary copper on the basis that the voltage between A and O be equal to that of the single phase with which comparison is to be made, a totally different result will obtain from that which would follow from assuming the voltage between the corners of the

Digitized by Google

triangle to be equal to the single-phase pressure; and, point of view considered, either result is correct.

This article is therefore an attempt to reconcile these varying results and show how each of them is obtained. As a preliminary we will suppose that a certain power W is to be transmitted a distance D at a voltage V and that the loss in a single line be w.

Let us assume the following letters of reference:

V = voltage of system.

W = watts transmitted.

D = distance transmitted.

c = current in a line of single-phase system of reference.

$c_1$ = current per line of polyphase system.

v = drop in a line of single-phase system of reference.

$v_1$ = drop in a line of polyphase system.

K = resistance of line of unit area and length D.

w = watts lost in one line of single phase system of reference.

$w_1$ = watts lost in one line of polyphase system.

With the single-phase system, see Fig. 2, it is plain that $w = v\,c$ where v is the volts lost in one line and c is the current in the system.

This we will retain as a standard of reference. It is evident that the necessary copper will consist of two lines of length D and resistance $\frac{v}{c}$. The sectional area of this copper is inversely proportional to its resistance and may be represented by

$$\frac{c\,K}{v}$$

where K is the resistance of unit area of length D. The total volume of the copper will then be

$$\frac{2c\,K\,D}{v} \qquad (1.)$$

which for convenient comparison with other values to be deduced we may call 100.

Let us now consider that we are to transmit the same power by means of a four-wire two-phase system with independent circuits, as shown in Fig. 3.

It needs no demonstration to see that it is a case of simply transmitting half the current over each of two single-phase circuits and that there will be necessary four lines of double the resistance of those of Fig. 2. There is, therefore, no saving of copper in this case, indeed the four-wire line is more expensive to construct than that using the two wires.

If we use the star system shown in Fig. 4 there will be no gain, for if the phases are balanced the system will behave exactly as one of independent circuits, and if unbalancing occurs, the amount must be specified before the economy of the line can be fixed. All this presupposes that the opposite terminals of the two-phase windings are producing the same pressure as the single-phase system with which they are compared.

Where the power is generated or received in a mesh system, as shown in Fig. 5, the voltage between

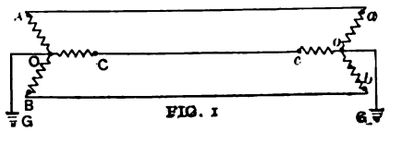

FIG. 1

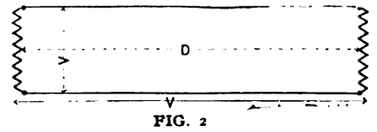

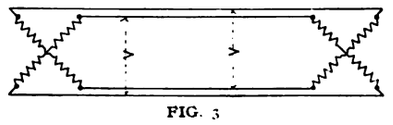

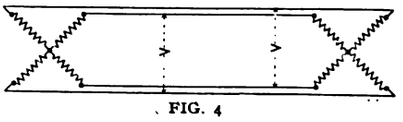

FIG. 2

FIG. 3

FIG. 4

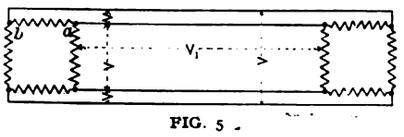

FIG. 5

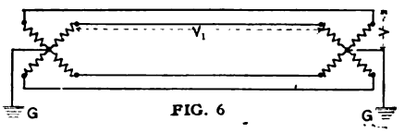

FIG. 6

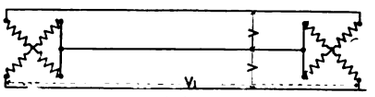

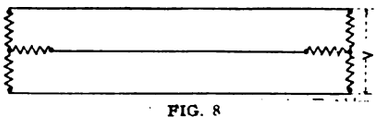

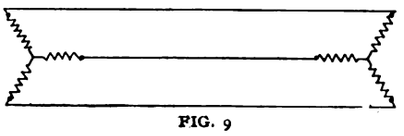

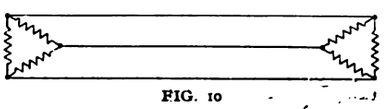

FIG. 7

FIG. 8

FIG. 9

FIG. 10

adjacent phases a and b is often considered to be the voltage of the system. If this is made equal to V there appears a decided saving in favor of the two-phase system. In this case the total energy transmitted is evidently 4CV where C is the current in one of the legs of the mesh, and at equal W, therefore, equal to one-fourth of the current in the single-phase system of reference. The current in one of the lines $c_1 = C\sqrt{2}$ and if the systems are to be of equal efficiency we have $4v_1c_1 = 2vc$, and as $C = \frac{c}{4}$ we easily deduce $v_1 = v\sqrt{2}$.

It follows therefore that the area of a single transmitting wire is

$$\frac{K\,c}{4v}$$

and the total volume of four such lines

$$\frac{K\,c\,D}{v}$$

or 50% of the copper necessary in single phase work.

The two phase system may be connected up star fashion with the common center earthed for purposes of regulation, as shown in Fig. 6.

If the load be composed of lamps, the voltage between one leg and the ground has sometimes been assumed to be the voltage of the system. A deduction will readily show that in such a case that the total copper equals

$$\frac{D\,K\,c}{2\,v}$$

or 25% the copper necessary for a single phase system.

Another case of two phase transmission, shown in Fig. 7, offers two more values:

If the voltage of the system is considered that between either line and the common return, the total power transmitted is $2Vc_1$ where $c_1$ is the current in the outer lines and is therefore equal to $\frac{c}{2}$. The current in the common return is not $2c_1$, but $c_1\sqrt{2}$, and if the loss of pressure in each wire is $v_1$, we have

$$2v_1\,c_1 + v_1\,c_1\sqrt{2} = 2\,v\,c$$
$$v_1 = 1.1715v.$$

The resistance of each of the outside wires is

$$\frac{2{,}3432v}{c}$$

The total volume $= \frac{2\,K\,c\,D}{2{,}3432v}$

and the volume of the common return is

$$\frac{D\,K\,c}{1.1715\,v\sqrt{2}}$$

making the grand total volume of copper

$$\frac{1.456\,D\,K\,C}{V}$$

or 72.8% of the copper used in an equivalent single-phase transmission.

If the voltage between the two outside lines is considered the basis of compari-

Digitized by Google

son and made equal to V, the voltage in a single coil of the system will be equal to $\frac{V}{\sqrt{2}}$, and if $c_1$ is the current in each of the two outer legs of the system, the total power will be $\frac{2 c_1 V}{\sqrt{2}} = c_1 V \sqrt{2}$, and placing this quantity equal to cV, we may obtain

$$c_1 = \frac{c}{\sqrt{2}}.$$

The current in the common return is $c_1\sqrt{2}$, or in this case c. If $v_1$ be the drop in the lines it follows, if the line losses are to be equated with reference to those of an equivalent single phase system, that

$$v_1 c + 2v_1\frac{c}{\sqrt{2}} = 2v c$$

whence

$$v = 8284\ v.$$

The volume of the outer wires is

$$\frac{2 D K c}{.8284\ v \sqrt{2}}$$

and the volume of the common return is

$$\frac{D K c}{.8284\ v}$$

The total copper equals

$$\frac{2.914\ D K C}{V}$$

or 145.7 of the copper necessary in a single phase system.

The monocyclic system, Fig. 8, is a variety of three phase system, the one phase being used for starting motors and then ceasing to act, uses the same amount of copper as a single phase system, plus whatever is necessary for the auxiliary circuit. The proper amount of this auxiliary copper does not depend upon any definite law, but depends upon the judgment of the constructing engineer, in much the same way as the neutral of a three wire direct current system is dimensioned from practical consideration.

The three phase systems are capable of analagous demonstrations to the foregoing performed in a similar way.

Perhaps the most common of these is the Y system shown in Fig. 9. The voltage between any two legs of the Y is usually taken as V the voltage of the system. The voltage of any one coil is equal to

$\frac{V}{\sqrt{3}}$ and the total energy $V\ c_1\sqrt{3}$ and placing this equal to Vc we find $c = c_1\sqrt{3}$

The power lost is $3\ v_1\ c_1 = v_1 c \sqrt{3} = 2\ v\ c$

hence $v_1 = \frac{2\ v}{\sqrt{3}}$.

The resistance of one line is therefore $\frac{2\ v}{c}$ and the total volume of copper becomes $\frac{3\ D K c}{2\ v}$

or 75% of the copper in an equivalent single phase system. This system is perhaps the most popular of all transmission systems and a convenient rule suggests itself in this connection. It is as follows: To calculate the proper size of wire for a three phase transmission, calculate as for a direct current transmission of the same length, voltage and economy. Divide the area of the wire thus found by two and the result will be the proper size of each of the three wires to be used in the three phase system. This rule puts the calculation within the reach of a wireman with a direct current education.

If the system has a grounded common junction, as shown in Fig. 1, the voltage of reference is sometimes taken as that existing between any wire and the earth, and the copper economy appears even better. The total transmitted energy is $3\ V\ c_1$ from which it is easy to see that $c_1 = \frac{c}{3}$. The power lost equals $3\ v_1 c_1 = v_1 c$, and placing this value equal to the power lost in single phase work we have $v_1 c = 2\ v\ c$ whence $v_1 = 2v$.

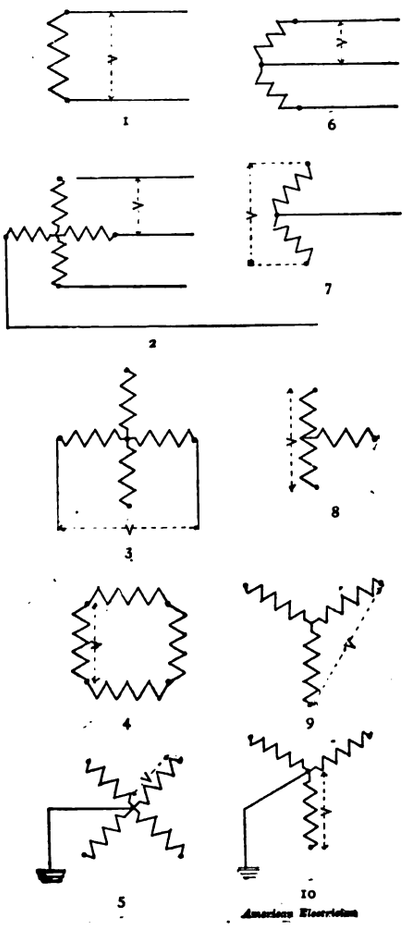

FIG. 10.

The resistance of each line is then $\frac{6\ v}{c}$ and the total copper is $\frac{K D c}{2\ v}$

or 25% of the copper necessary in single phase work.

In the mesh combination the same result as with the Y system obtains. The diagram is shown in Fig. 10.

The voltage of reference V can obviously be none other than the voltage between any two corners of the mesh. The total power transmitted is $V\ c_1\sqrt{3}$ for the current in one of the branches of the mesh is $\frac{c_1}{\sqrt{3}}$ where $c_1$ is the current in the line. Equating this value to the single phase power we obtain

$$Vc_1\sqrt{3} = Vc$$

whence $c_1 = \frac{c}{\sqrt{3}}$

The power lost $3v_1c_1 = 2\ v\ c$

whence $v_1 = \frac{2\ v}{\sqrt{3}}$.

The resistance of a line equals $\frac{2\ v}{c}$, and the total volume of copper $\frac{3\ D\ K\ c}{2\ v}$ as before.

In closing this article a recapitulation of these results and a few words of comment will be appropriate.

| | | Copper. |
|---|---|---|
| 1. | single phase. . . . . | 100 |
| 2. | two-phase independent . . | 100 |
| 3. | two-phase Y balanced. . . | 100 |
| 4. | two-phase mesh balanced . | 50 |
| 5. | two-phase y center to earth | 25 |
| 6. | two-phase three wire . . . | 72.6 |
| 7. | two-phase three wire . . . | 145.6 |
| 8. | monocyclic . . . | 100 + auxiliary |
| 9. | three-phase Y. . . . . | 75 |
| 10. | three-phase y comm n junction grounded . . . . . | 25 |
| 11. | three-phase mesh. . . . . | 75 |

It is manifestly unfair to make comparison between single and polyphase transmissions using any but the highest voltage of the polyphase system, but it has been done and has misled many. The machine and the line has to be insulated for the higher voltage and should be so rated. Results 1, 2, 3, 7, 8, 9 and 11 are in the writer's opinion the only ones that are honestly comparable.

It will be also noted that the drop $v_1$ in many of the polyphase systems was greater or less than v, the drop in the single phase system. The above demonstrations assumed equal line loss in watts, which is the more important in long distance work. In local distribution for lighting purposes the systems have been compared for equal line losses in volts, which give still different ratios of copper economy.

# Some Recent Electrical Patents.

**A Means for Starting Arc Lamps on Constant-Potential Circuits**—At the instant of closing the circuit of an arc lamp across constant-potential mains the carbons are together and the full voltage is

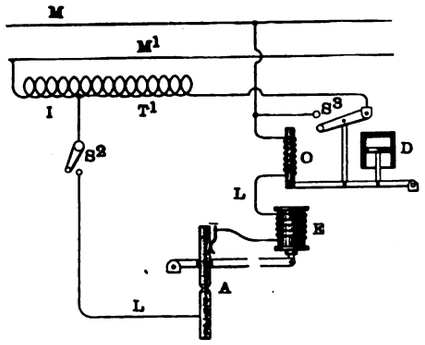

FIG 1.—A STARTING DEVICE FOR ARC LAMPS.

resisted only by the series resistance and solenoid, causing a great rush of current. This draws the carbons so violently and suddenly apart that the carbon vapors, upon whose existence the arc is dependent, do not have time to form and the arc is broken. This interrupts the circuit and the carbons coming together again the action is repeated, causing chattering. This has been reduced in the past in several ways. One is by the use of soft-cored carbons which give off their vapors more quickly but which are expensive and short-lived. Another method is to use a dash-pot to restrain the sudden movement of the controlling magnet, but this very restraint necessitates the flow of an excessive current until the dash-pot is overcome. Still another method is the use of a series resistance considerably greater than that necessary for smooth running, but this is of course wasteful. Messrs. H. A. Wagner and D. W. Roper of the Missouri-Edison Company, St. Louis, offer another means of overcoming this disadvantage which consists in starting the circuit with a reduced current, sufficient to heat the carbon tips to redness but insufficient to act upon the series magnet and strike the arc. In a patent recently issued they broadly claim this method and describe various means of accomplishing it, one of which for alternating-current work is illustrated diagrammatically in Fig 1. Here M and $M^1$ are a. c. low-voltage mains supplying the arc shown at A, through an auto-transformer or economy coil $T^1$ for reducing the voltage. The apparatus is shown in the open-circuit position. To start the lamp the switch $S^3$ is closed, giving a circuit through a part, I, of the economy coil, the switch, $S^3$, the wire, L, the arc, A, the series magnet, E, and the solenoid, O. The right-hand coil of the auto-transformer is on open circuit so that the left end section which is in series with the arc acts as an inductive choking coil, reducing the current to a value insufficient to energize the magnet, E, but sufficient to heat the tips of the carbons. This current is also sufficient to energize the magnet, O, which closes the switch, $S^3$, slowly on account of the dash-pot, D. When the switch, $S^3$, is closed the winding, I, is instantly transformed from a choke coil to one side of a constant-potential auto-transformer or compensator, giving the lamp sufficient current to strike the arc. On account of the previous heating the carbon vapors are instantly thrown off and the arc burns without chattering. Patent No. 631,975.

**A Laminated-Contact Switch.**—Switche of the ordinary knife and jaw type, used for the enormous currents generated by low-tension machines of several hundred or thousand kilowatts capacity become of unwieldy proportions in order to provide sufficient area of contact as well as to dissipate the power wasted within them with-

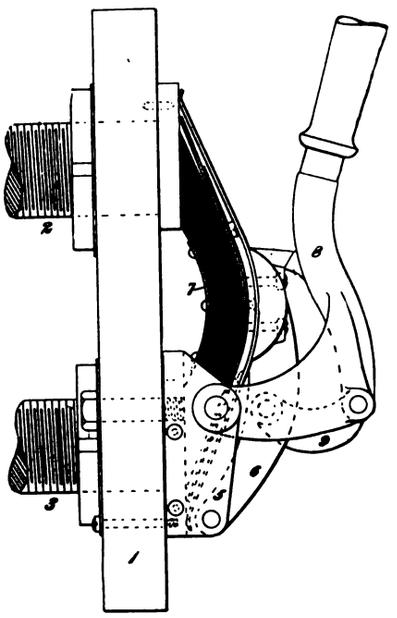

FIG. 2.—A LAMINATED CONTACT SWITCH.

out overheating. Owing to the friction due to the binding of the knives in the jaws upon which they depend for good contact their operation becomes quite too difficult for hand work. On this account many makers are adopting a contact made up of the ends of many laminated leaves of spring-tempered copper bearing upon solid copper blocks, a type of contact quite generally used in England, but hitherto little used in this country except in the main contacts of the General Electric Company's circuit breakers. The Westinghouse Company has adopted this type of contact for its pneumatically operated circuit breakers and throw-over switches for large railway generators and a patent recently issued to G. Wright and C. Aalborg describes the construction of the same type of switch as designed for hand operation. A side elevation of the switch is given in Fig. 2, which may be briefly explained as follows: The base or switchboard panel is shown at 1 and through it pass the contact studs, 2 and 3, ending respectively in bearing plates against which press the ends of the laminated contacts, 7. These are held at their middle point in a clamp which is attached to a link, 6, pivoted to the lower terminal, at 5. To the link, 6, is also pivoted another link, 9, which connects with the handle, 8. This when thrown up locks the laminated contact in the closed position by means of a toggle joint, and when thrown down opens the circuit by lifting the laminations directly away from the contact plates. Patent No. 633,771.

**Combined Telegraph and Telephone.**—For some purposes, such as train dispatching, the telephone is on account of its speed superior to the telegraph, but inaccuracies are apt to creep in, especially in the transmission of numbers or names. To obtain the speed of the one method of transmission for the greater part of a message and the accuracy of the other for the transmission of numbers, names or other important or difficult words, Mr. R. M. Bailey has patented the combination of a telephone and telegraph in the manner described below. Fig. 3 shows a sketch of the arrangement indicating a transmitter of the usual granular form connected as usual in a local battery and microphone circuit. Mounted on an extension of the transmitter-holding arm is the sounder of a local telegraph circuit. The sounder is operated in the usual way by means of a key and battery. The transmission of the telegraph message to the distant receiver is accomplished solely through the vibration set up by the sounder in the transmitter arm, and the consequent noise set up by the microphonic transmitter in the telephone circuit. In using the instrument one would talk as usual until a name or number or other word difficult to make clear arose, this word being tapped off on the key. Patent No. 630,841.

**A Single-Phase Induction-Motor Starting Device.**—As is well-known simple single-phase induction motors without com-

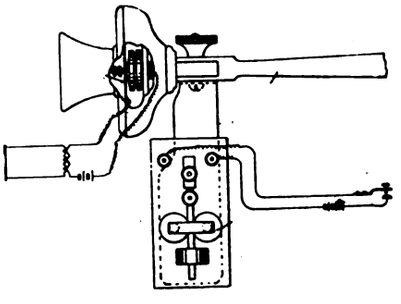

FIG. 3.—A COMBINED TELEGRAPH AND TELEPHONE.

mutators or auxiliary short-circuited or acceleration coils have no tendency to turn in either direction when their rotating parts are at standstill. If, however, the rotor is given a turn by hand in either direction and is disengaged from

Digitized by Google

the load it will continue to turn in the same direction and gradually run up to full speed, after which it will exert its full power practically as well as does a polyphase induction motor. Like the polyphase induction motor, also the torque which it will exert when first started off by hand can be greatly increased by inserting resistances in the circuits of the secondary or rotating windings instead of leaving them short-circuited as they should be when the motor is running at full speed. If the coils of the secondary or rotating member of a single-phase motor are fitted with collector rings connected to external resistances of the proper value the slightest turn given the secondary will serve to start it off. For large motors, however, of 100 h. p. or more, it is difficult to give this turn by hand, and Prof. Riccardo Arno, the well-known Italian scientist, has patented a means of giving this slight turn electrically. The secondary of such a motor should have three collector rings connected at equal intervals to the secondary winding, and Prof. Arno's method consists in open-circuiting for a brief instant in starting the line from one of these collector rings. This gives an unbalanced torque on the repulsion principle to the secondary circuit, which tends to set itself so that the alternating field from the primary shall thread through the open-circuited section of the secondary instead of the short-circuited section. This tendency gives the rotor a part of a turn and by properly closing the remaining secondary connection the motion thus started will be maintained and the motor will run up to speed. Patent No. 631,919.

**A Means of Reducing Sparking at the Contacts of Circuits Including Magnets.**—The fact has long been recognized, and has been mentioned in some works on telegraphy, that the sparking at the contacts of a local telegraph circuit can be reduced by winding the magnet with two wires connected in parallel with each other. That is to say, if the coil of a magnet, instead of being wound with one wire of the proper cross section, is wound with two wires of half that cross section and the

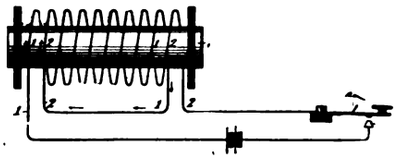

FIG. 4.—AN ANTI-SPARKING WINDING FOR MAGNETS.

same number of turns, these two windings being connected in parallel and giving the same magnetizing effect with a given current as does the single winding, then the sparking will be less. Messrs. Chas. L. Buckingham and Emil Germann, in their experiments with high-speed printing telegraphy, have discovered that a magnet wound with two wires on the duplex principle, i. e., the two wires lying side by side throughout their length, these two wires being connected in series, gives less sparking effect than does the same magnet wound in the ordinary way with the same size of wire and the same number of turns. In fact, they claim that by this means "the spark at points of rupture may be almost wholly eliminated." The action is probably due to a condenser action between adjacent turns having considerable difference of potential, the electrostatic charges from which balance to a certain extent the self-induction. The inventors claim broadly this method of winding magnets for the purpose of protecting contacts against destructive sparking. It is possible that the same method may be used in alternating-current apparatus to reduce somewhat the self-induction, its use in this way being outside of the claims of the patent No. 634,198.

**The Construction of Fly-Wheel Alternators.**—In dynamo machines of the rotating-field type there is a tremendous outward pull of the poles, made up in part of the centrifugal force, and in part of the attraction of the pole pieces for the external armature. To fasten laminated poles securely against this force and still

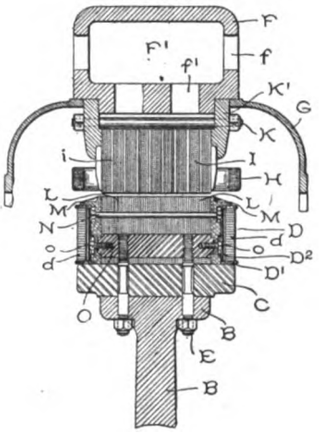

FIG. 5.—SECTION OF FLYWHEEL ALTERNATOR.

make them readily removable for repairs without dismantling the whole machine is no easy problem. In small machines the laminations are dove-tailed into the hub or yoke supporting them, but in large machines of the fly-wheel type the yoke upon which the field pieces are mounted becomes a large ring, the dove-tailing of which would be an expensive process and would weaken the ring which must stand considerable rim tension. The General Electric Company in such machines punches a large hole through the field laminations and passes through this hole a heavy bar, which is then securely bolted to the yoke. The arrangement is patented by Mr. H. G. Reist and is shown in Fig. 5, which is a longitudinal section through a field pole and the armature of such a machine. B is one arm of the spider driving the rim, C, to which is attached a pole, D. This is made up of the usual laminations, LL, forced together by means of the bolt, N, and through which passes the steel bar, O. This bar has a shoulder at each end, against which the end plates, MM, are seated and bolted by means of the bolts, oo. The field pole is fastened in place on the rim of the fly wheel by screwing the bolts, E, into the bar, O. In this case the same bolts serve also to fasten the fly wheel rim to the spider. The field winding is of the edgewise type, shown at d, consisting of a copper ribbon laid up on edge around the pole. The construction of the armature is indicated in the upper portion of the figure, in which I is the armature-iron, held in place by the bolts K between the end rings K'. Guards, G, protect the coils, H, against accidental injury. The sustaining structure, F, of the armature is cast with a hollow body, F', into which lead openings, f. Other openings, f', allow free circulation of air

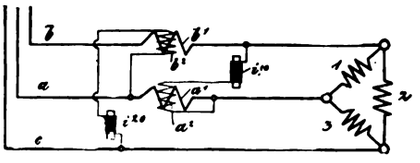

FIG. 6.—CIRCUITS OF MOTOR METER.

around the armature-iron, the usual spaces, i, being left between the groups of laminæ by the insertion of the now well-known space-blocks. Patent No. 630,409.

**A Three-Phase Motor Meter.**—In alternating current meters of the induction type it is necessary to obtain a lag of the current in the potential or shunt winding 90° behind the impressed e.m.f. to give accurate indications on inductive loads. The lagging shunt current is then made to excite one pole or set of pole pieces and the series current is led around another set, these two sets of poles acting together on a short-circuited secondary to give a split-phase induction-motor action. In three-phase feeders or mains the current passing through any wire is not in phase with the difference of potential between any two wires, and it is impossible to get a difference in potential from which to obtain the proper lag of 90° without the use of the Y-box or some equivalent arrangement. Mr. G. Hummel has conceived the simple idea of taking the differences of potential as he finds them and setting up a lag in each shunt circuit of 30° behind the impressed e.m.f., thereby obtaining the desired 90° behind non-inductive current in the series circuit, instead of going to the trouble of using a Y-box in order to obtain an e.m.f. in phase with the current in the incoming wire and then causing a lag of 90° behind the e.m.f. The arrangement is shown in the accompanying diagram, Fig. 6, in which a b c are the incoming leads carrying current to the delta-wound machine, 1, 2, 3, this current being measured on the two-wattmeter method. Considering the meter motor containing the series coil, $a^1$, connected in the lag, a, its shunt coil, $a^2$, is connected in series with the impedance coil, $i^{10}$, between the legs, a, and b, of the circuit. The impressed e.m.f. between these two legs is 60° behind the current through leg, a, when the load is non-inductive, and a further lag of 30° is easily obtained by means of the induction coil, $i^{10}$. In the same way the other meter motor, $b^1$ and $b^2$, is connected into another phase. Patent No. 633,695.

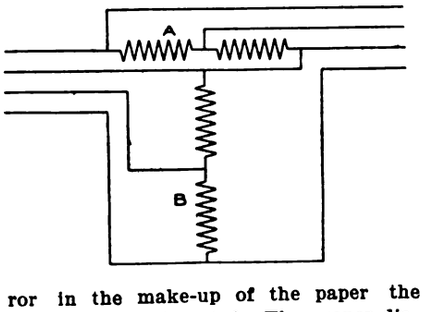
# NOTES.



**The Largest Gas Engine** in the world is one now being made by the Westinghouse Machine Company at the works in East Pittsburgh. The engine will be rated at 1500 h. p. Its cylinders are 34x60 inches in dimensions, its extreme length 44 feet, width 12 feet 4 inches, and height over all 27 feet.

**Street Railway Exhibition to be Held in London.**—The proprietors of the "Tramway and Railway World" have arranged for an international tramways and light railways exhibition, the first of its kind in Europe, which will be held at Agricultural Hall, London, from June 30th to July 11th, 1900.

**Castings for the Single-Phase Rectifier.**—Mr. W. F. Brown of So. Norridgewock, Maine, announces that he has patterns for the rectifier described in the June issue of the American Electrician and will be able to supply castings at a reasonable price. He will not be able to supply armature punchings.

**The New Ownership of the Chicago Edison Company.**—The Chicago Edison and Commonwealth Electric properties of Chicago have been transferred to a new company which is practically the Whitney-Widener-Elkins syndicate, which already owns extensive traction interests in Chicago and lighting and traction interests in New York and other cities. The new company will have a capital stock of $25,000,000, and be bonded for the same amount. Edison stockholders will get $2.00 for $1.00 of par valuation of their old stock in the 4 per cent bonds of the new company and a bonus of 50 per cent in the new stock.

**A Simple Two-Phase System of Secondary Mains**—In the last issue of the American Electrician, page 473, a note appeared under the title given above illustrated by a diagram for which by an unfortunate error in the make-up of the paper the wrong cut was inserted. The proper diagram showing the system of secondary mains is given herewith. As explained in greater detail last month, four wires carry one phase on the three-wire system to lamps and both phases to motors.

**An Electrically Operated Dry-Dock Equipment.**—At the League Island Navy Yard of the United States Government there is to be constructed for the use of the Navy a large timber dry dock, the entire pumping and other power equipment of which will be run by electric motors supplied by an isolated plant to be especially installed for the purpose. The generating plant will consist of two vertical cross-compound engines, each coupled to two 250-kw., 125-volt dynamos, constituting two three-wire sets. The largest motors will be three of 450 h. p. each, direct connected to the runner shafts of the main pumps. There will also be 8 capstans and 3 winches, each driven by a motor of not less than 35 h. p., besides several other auxiliary motor-driven machines.

**An Odd Form of Bridge.**—At Rouen, France, there is in service a bridge the highway of which consists of a hanging platform which moves from side to side of the river. The bridge proper is of the suspension type, 160 ft. above the water level, and carries a track on which runs a trolley, from which is suspended a platform at the street level. This platform travels from side to side of the river, accommodating passengers and vehicles. This odd arrangement, resembling in some respects a ferry boat and in other respects a bridge crane, is driven by two electric motors mounted on the traveling platform and transmitting their power to the wheels of the trolley overhead by means of a rope drive. The platform has an area of 35x40 ft. and weighs 20 metric tons, the total moving weight of trolley, cables, platform and live load being over 100 metric tons.

**A Peculiar Central Station Accident.**—At 3 o'clock in the afternoon of October 18th a large water tank, holding 50,000 gallons of water, burst, and crashed through the roof of the power house of the Ocean City Electric Light Company at Ocean City, N. J. The water tank stood on a framework 50 feet high, immediately adjacent to the power house. Its fall wrecked the plant, breaking the steam pipe flanges and flooded the generators. Fortunately only one man was injured by the accident. A few minutes after the crash Superintendent H. M. Kalbach started running a temporary steam connection, and in three hours and 25 minutes the water works pump and the incandescent service were in operation, and the following evening the center of the town was again lighted with arcs. In spite of the fact that the water had to be pumped out of the power house, the dynamos being deluged and soaked, Superintendent Kalbach reports that they worked splendidly and gave no trouble whatever.

**The Electrical Distribution of a Time Standard.**—In a paper presented before the electrical section of the Franklin Institute, Mr. James Hamblet, manager of the telegraphic time service of the Western Union Telegraph Company, gave the following information about the telegraphic time systems in this country:

Previous to the adoption of a standard time, there were over 80 standards throughout the United States. In the State of Ohio there were eight different standards. Now there is only one standard of time in the whole country, differing only by even hours; and the time is sent daily from Washington to the entire country, so that the whole question is simplified. The Western Union Telegraph Company distributes the time from Maine to California. In New York there are something like 1500 self-winding clocks, corrected every hour by the standard clock of New York. In New York City there are 23 circuits extending all over the city from Western Union Building, 195 Broadway. The standard clock sends out its beats over the city every two seconds, beating the even seconds, zero, 2, 4, etc., omitting the 58th second every minute, thus making a pause at the beginning of each minute. Every fifth minute 20 seconds are omitted. Many of the prominent jewelers (nearly 200 in number) have sounders which tick every two seconds. The clock acts upon the 23 circuits by means of 23 relays, located near the clock in the time service room, and at each hour the standard clock sends a strong synchronizing current to the whole 1500 clocks in the city.

**A Comprehensive Tunnel Plan Proposed for Chicago.**—An ordinance has been introduced in the Chicago Common Council which grants permission to the Chicago Subway, Arcade and Traction Company to build and operate a comprehensive system of subways beneath the surfaces of the streets, decidedly in advance of the present needs, but laid out in an evident appreciation of the demands of great cities, perhaps 100 years hence. The ordinance gives power to construct, maintain and operate in the city of Chicago for a period of 94 years a system of subterranean ways, arcades, tunnels and conduits under all streets, avenues, parks, rivers, etc., to operate street railway cars in said tunnels, and to lay water, drainage and gas pipes and electric wires. Permission is also included for building a terminal station under certain city property, for which the company is to pay an annual rent equal to 5 per cent. of the valuation of the land. The compensation for the right to build and operate the subway system is 2 per cent. per year of the gross receipts of the company. The ordinance also gives permission to build a system of sewers at a lower level than the present sewers of the city, and to collect sewage and garbage in the district occupied by the system of the company; the sewage and garbage to be treated at reduction works to be operated by the company. All tunnels and arcades to be built are to be at least 18 feet in width and 13 feet in height. While this immediate move may be only a plan to obtain in advance and at no cost rights of great value, it indicates the originator's ideas of future urban needs.

**The Electrical Application of Dental Anesthetics.**—Probably few electrical engineers, except those who have had considerable experience in the dentists' hands, realize how general is the use of electric current in the application of local anesthetics to the teeth. This function of the current is called by dental surgeons "cataphoresis," and is simply the forcing of anesthetic agents, such as cocaine, through the tissues of the tooth by means of a continuous current of electricity. The phenomenon is simply that known to physicists as electrical osmosis, by which a liquid is carried through porous walls or diaphragms when a current is transmitted through them. The temporary deadening of the sensitive nerves is the most important use of this application of the electric current. It has been found, however, that if the operation is prolonged the nerve is painlessly killed, giving a far more satisfactory method of accomplishing this result than the old slow and painful treatments. Experiment has shown that the pulp of the teeth can be anesthetized and extracted painlessly and immediately by "cataphoresis." A third use of the same application is the "bleaching," as it is called, of discolored teeth after the death and disintegration of the pulp. In this application a bleaching solution is used instead of anesthetics and the electrical current carries it into and disperses it more fully through the substance of the tooth than is possible by any other means so far discovered. Chemistry has not yet suggested a proper decoloring agent for the bleaching of teeth discolored by amalgam filling, though there is no doubt that when this is discovered the electric current will serve to carry it to the desired point. The "cataphoric outfit," as it is called, consists of a number of dry cells, an electrode to be applied to the teeth and a hand electrode for the other terminal, a rheostat for adjusting the current and a sensitive milli-ammeter for measuring it. Such outfits are now put on the market by the larger dental manufacturers.

---

**A Two-Speed Induction Motor.**—As is well known, the alternating current induction motor runs most efficiently at speeds nearly synchronous with that of the rotating field set up within it, any considerable reduction of speed being accompanied by a corresponding waste of energy. An ingenious means of changing the speed of rotation of the field set up by currents of a given number of cycles has recently been incorporated by the General Electric Company in some large motors built for driving the grinding tables in a plate glass manufacturing establishment. The variation is accomplished by changing the connections of the windings of the motor by throwing over a switch, the result being a change of the speed of rotation in the ratio of 1 to 2, a ratio well suited to the needs of the machines driven, since they are often required to run at half speed. The general principle of the change is to double the number of poles for the lower speed and thereby cut in two the angular distance through which the rotary field passes during one alternation of the current. The special arrangement of the coils for this purpose is indicated in the partial development of the stator winding, Fig. 1, which shows two adjacent coils of one phase reduced to a unitooth representation. These coils are of fractional pitch for full speed of the motor, spanning a trifle over 50 per cent. of the distance between their centers. For full speed they are so connected that at any instant current passing through them will set up a north pole under one and a south pole under the other, the space between them being neutral. For half speed they are so connected that each one would tend at the same instant to set up the same polarity. If this is north there will be a south pole induced between them, thus doubling the number of poles of the machine and cutting in two the speed. The connection of the numerous coils of the three different phases in such a way as to most simply accomplish this change of circuits is indicated by the vectorial diagram given in Fig. 2. For running at full speed the windings are connected together on the usual star or Y system, and supplied through the three wires, 1, 2 and 3, the terminals, 4, 5 and 6, being on open circuit. For running at half speed the three wires, 1, 2 and 3, are short circuited to each other and the incoming power is brought through wires, 4, 5 and 6. It will be noted that between the legs, 4, 5 and 6, there is a small Y-connected winding, while the windings outside of this central Y constitute, through the short circuit mentioned above, another Y in parallel with the first. It will be also noted that at any instant under the latter connection current through a coil of the central Y flows in the reverse direction from that through the other coil of the same phase, while with the former connection for full speed the currents through the two are in the same direction, the same reversal taking place also in the other phases. The windings of one phase of every other pole around the machine are connected in one section, the intermediate poles being in the other. Thus the change of the circuits from 1, 2, 3 to 4, 5, 6, and the short circuiting of 1, 2, 3, reverses the alternate poles, as described above. It will be noted that with the low-speed connection there are half as many turns between terminals as with the high-speed connection, which would give a greater density at the lower speed but by connecting the coils to give half speed in series and full speed in parallel this condition can be reversed.

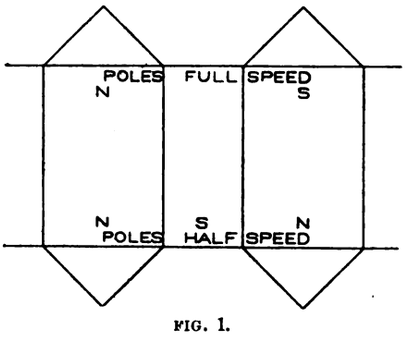

FIG. 1.

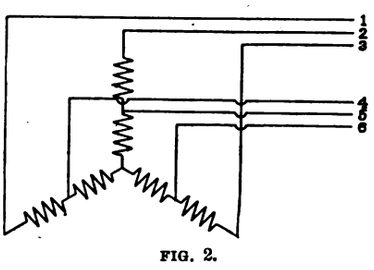

FIG. 2.

---

**The Schlicht Process of Supplying Air to Furnaces.**—During the past year the Schlicht Combustion Process Company, New York City, has been exploiting and introducing a most remarkable and apparently paradoxical method of supplying air to furnaces.

By this new system the fresh air containing the oxygen for the fire is brought down through the stack and flue passages, the remarkable and apparently incomprehensible feature being the fact that the fresh air is brought through the same passage that conducts the waste gases upward and in immediate contact with these gases. The apparatus consists simply of a tube centrally inserted in the top of the stack in such a way that the products of combustion will pass out through it and there will be a draft of fresh air entering around it downwardly into the stack and escaping with the products of combustion up through the central tube. The claim is made that if the ash-pit doors are closed, or nearly closed, this fresh air entering around the outer edges of the stack opening, will pass down the whole length of the stack and find its way on through the breeching and the flues of the boiler—if the course is not too complicated—to the fire, the outer shell of fresh air flowing downward in the flues and stack remaining practically unmixed with the inner column of heated burned gases passing upwardly within it. Under such conditions the incoming air to the fire becomes heated on the regenerative principle and the claim is made that there is a great reduction of the excess oxygen and of unconsumed carbon monoxide below that found when the draft is drawn as usual through the grate bars. In cases where the passage of the gases is unusually tortuous, as where economizers are used, or several boilers discharge into one stack, the fresh air is not introduced at the top of the stack but is led in through an opening into the air passages at some point nearer the combustion chamber. The claim is made that in spite of the draft which would seem to draw the fresh air from such an opening straight toward the stack, the air will pass in the opposite direction toward the fire, will flow over and through the fuel and will then return upon its previous course, pass its point of entrance and escape through the stack.

### The Various Means of Keeping Boilers Clean.

The steam boiler, so far as the materials entering and leaving it are concerned, is nothing more nor less than a mammoth still. All the water that enters it leaves it in the form of steam and if condensed becomes distilled water, chemically free from impurities. If the water that enters it contains any impurities whatever these must accumulate in the boiler and rapidly become concentrated to such an extent that they are deposited, eventually covering the boiler heating surfaces with a coating of solid matter or sludge, which seriously impairs the output of the boiler since this output is directly dependent upon the amount of heat that can be transmitted through the heating surfaces.

Many have been the methods and devices designed for purifying the water either before or after it enters the boilers, or for chemically acting upon the impurities so as to prevent their deposition and render them removable by blowing off. In surface condensing plants where the water from the hot well is returned to the boiler the same water circulates again and again through the system of boiler, engine and condenser. The only impurity that is introduced in this repeated circulation is the oil used for cylinder lubrication. Many arrangements are used for eliminating this, among them centrifugal oil separators in the exhaust steam piping and mechanical filters in the feed piping. A positive and simple remedy for the whole trouble of boiler impurities would be to use surface condensers and no cylinder lubrication, but steam engine practice appears to be hardly ready for this rather advanced remedy, although it may be forced upon steam users by increasing steam pressures and increased difficulties of lubrication therewith.

When the exhaust steam or condensed water is thrown away and a fresh supply of feed water is introduced there is a constant influx into the boiler of impurities in solution or in suspension in this water. The former, i. e., those in solution, are to a large extent insoluble in hot water so that the heating of the water precipitates them. By simply heating the water before it reaches the boiler they may be precipitated in auxiliary apparatus more easily cleaned than is the boiler itself. Impurities carried along in suspension as a rule collect at the water level within the boiler and may be skimmed off therefrom by cleaners of the surface blow-off type, a number of which are described in an article on other pages of this issue. This article is the beginning of a number of discussions of the whole range of purifying apparatus for use with steam boilers, which articles will be continued regularly in these columns until their completion.

### The Hull as a Return for Marine Plants.

In the leading article of this paper there will be found a description of a high-grade English ship-lighting plant in which the hull of the vessel is used as the return conductor of the distributing system. In this country marine equipments were at one time arranged in this way but the practice has gradually gone out of favor, a complete two-wire insulated system now being the universal rule in American-built ships.

Among the reasons which have been given for this change in American practice are the added risk of grounds, the deflection of the compasses and the danger —probably more fancied than real—that electrolysis or heavy burn-outs would seriously affect the ship's structure or plating. That the English builders use the system in such a ship as that described on another page, which is the largest and most expensive craft afloat, proves that none of these objections can be very serious, and that there must be compensating advantages.

The first and chief of the advantages is of course the reduced cost of the wiring. As the return circuit has an enormous cross section there is practically no drop of voltage in it. The whole drop being concentrated in one side of the system the conductors can be made one-half the cross section necessary to give the same drop in a two-wire system; thus the amount of copper is reduced 75 per cent, a reduction greater than that obtained by the use of a three-wire system.

In addition to the reduced amount of material the work of construction is greatly simplified. No twin wires are necessary, each feeder, main and branch being a single conductor with single-pole switches and fuses. The switchboard is also greatly simplified, there being no need of a negative bus and switches and double-pole fuses. Indeed, there is no need of even running the negative leads from the machines to the board, although in the plant referred to above the single-pole fuse for each machine has been put on the negative lead between the machine and ground in order to protect against grounds within the machine, and for the sake of convenience the fuse has been placed upon the switchboard.

This hull arrangement gives twice the strain on the insulation between the positive and ground that exists in two-wire

Digitized by Google

insulated systems, but this strain is slight in such low tension circuits, insufficient to do physical harm or break down insulation with any dielectric strength whatever. With two-wire systems in case the insulation of one polarity gives away at any point the ground immediately becomes a network carrying the current from the fault to any weak point that may develop on the other polarity. In one-wire systems all the insulation is placed to one side of ground and a weakness at any point through half the insulation is not distributed to any weak points through the other half.

An old rule has been revised by some modern wit into the form "put all your eggs in one basket and then watch that basket." To paraphrase this revision the English prefer in marine plants to put all their insulation on one pole and then watch that pole.

**A New Departure in Alternating Current Regulation.**

It is well known that the drop in alternating-current generators with increase of load is as a rule much greater than that in direct-current machines of the same size and with the same load increase. This is due to the self-induction of the windings caused by magnetic leakage from the armature coils that does not pass through the field coils. In addition, when the load of an alternator becomes inductive, the armature exerts a direct demagnetizing effect upon the field for which there is no analogue in direct-current machinery.

Single-phase alternators in small sizes are customarily composite-wound, the current passing out to the line or a derived current proportional thereto being rectified and used to help excite the fields. While this current is effective for non-inductive loads, when the load becomes inductive and the demagnetizing action of the armature is increased thereby, the composite winding fails to make up for it and the voltage of the machine falls just at the time when it should rise in order to overcome the increased inductive drop of lines and transformers.

Composite winding does not adapt itself to polyphase machinery and is rarely used on large generators. The result is that such machines in order to obtain close regulation are necessarily rated at an output frequently much less than they could carry if limited only by danger of overheating. In other words, the machines are more heavy and more expensive per kilowatt output than would be the case if it were not for difficulties of regulation.

On another page there will be found a description of a new line of alternators which are in a sense compounded, the compounding being effected through the exciter on a new principle of alternating-current regulation. In a paper recently read by Mr. H. G. Reist before the Ohio Electric Light Association the results obtained by this method of excitation were illustrated by a striking example which may be quoted as follows: "I have seen a 50-h. p. induction motor started from a 75-kw. generator with a drop in potential on the line just sufficient to fluctuate the voltmeter and lasting perhaps one-half second, but the effect on the lights could be detected only on close observation. At the same time it was noted by the tachometer on the machine that there was a momentary drop in speed so that beyond a doubt the slight fluctuation was due to this cause." Such results are far from attainable in ordinary separately excited or composite-wound machines and indicate a new departure in alternating-current regulation which will go far toward overcoming the previous poor qualities of alternating-current machinery in this respect as compared with direct-current machinery and will allow the more general use of a.c. motors without serious disturbing effects.

**An Expedient for Troubles in Parallel Running.**

With a battery of compound wound direct-current machines which usually run perfectly in parallel with each other it often occurs that one machine suddenly develops a tendency to alternately shirk the load and attempt to carry the whole of it. This tendency—as is well known—is due to poor contacts somewhere in the circuit, such poor contacts being liable to develop at any time owing to a burned switch blade, a loose nut or other causes. It might be incidentally remarked right here that the poor contact need not be in the equalizer since the satisfactory running of compound wound machines together depends on the perfection of paralleling the series fields and a poor contact in the positive bus bar (if the series fields are on the positive side of the system) may disturb this paralleling.

When this trouble does occur it usually requires some time to locate it, and any means of operating the machine affected during this time may prove valuable in stations the generating equipment of which is heavily loaded. Such a means may be borrowed from experience in alternating current stations. As is well known, the division of the load between alternating current generators depends solely upon the governors of the engines driving them. If two engine-driven alternators are running in parallel and the governor of one is thrown out of service with the cut-off fixed so as to give steam enough for, let us say, 100 kilowatts, this unit will continue generating 100 kilowatts and the other one will supply the balance necessary to carry the load, its governor taking up the whole of the fluctuations. This method of working is quite commonly used where the loads are reasonably steady and particularly in water power plants where individual governors on each machine are likely to give trouble.

In direct current plants the same expedient may be adopted for machines giving trouble in the manner pointed out above. If one machine unexpectedly develops a tendency to see-saw its load the trouble may be temporarily remedied until a permanent cure can be found by blocking its governor and running its engine at fixed cut-off. It will then deliver to the bus bars a constant number of kilowatts at a voltage determined by the excitation of the other machines. The reason for this action and for the fact that any change either of its shunt or series field does not disturb its load may be explained as follows. If, for example, the current through its series field is suddenly increased the voltage will tend to rise above that of the other machines and the output will tend to increase. The lack of steam to give this increased output will check this tendency and the speed will fall, maintaining the voltage and output at the previous values, the engine thus automatically adjusting its speed so as to deliver practically the same energy to the bus bars whatever the field excitation may be.

This expedient is a valuable one in cases where the equalizer fails and the series field would otherwise tend perhaps to weaken the magnetism and make the machine run as a motor and race, carrying the engine with it. The blocking of the governor in this case absolutely prevents any reversal of the current through the series field. While of course it is unsafe to run a machine in this way without closely watching it when the load is likely to fall below the output for which it is set, still there are many cases where the smallest probable load is greater than that generated by one machine. In such cases this method of running is safe.

# THE APPARATUS FOR THE COMMERCIAL GENERATION OF OXYGEN AND HYDROGEN BY THE ELECTRIC CURRENT.

BY W. S. FRANKLIN.

During the year 1895 a novel form of electrolytic generator for oxygen and hydrogen was constructed and tested at the physical laboratory of Iowa State College.* During 1896 this generator was greatly improved, and a large generator of twenty cells was constructed and tested. The results of this test showed that practically pure oxygen could be produced at the cost of 1 cent per cubic foot (counting hydrogen as of no value), rating electrical power at 2 cents per kilowatt hour. This early type of generator was identically the same in design as the generator described below, except that the electrode frames and all pipes were made of lead and the electrolyte was dilute sulphuric acid.

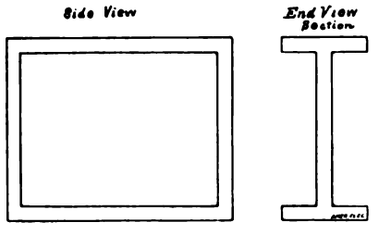

FIG. 1.

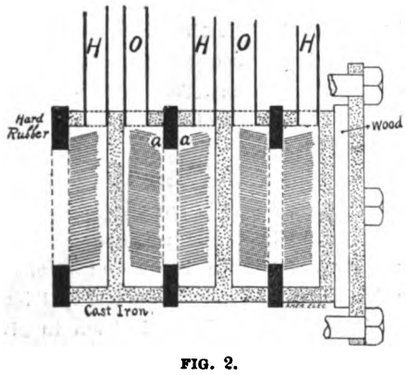

FIG. 2.

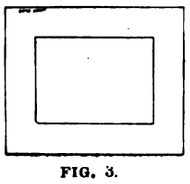

FIG. 3.

During 1898 an electrolytic generator was constructed and tested† at the physical laboratory of Lehigh University. This generator was made by bolting together a number of massive cast iron frames of the form shown in Fig. 1. These frames were separated by hard rubber plates, as shown in Fig. 2, and the central portion of each hard rubber plate was cut away, as shown in Fig. 3. The chambers between the frames were filled with caustic soda solution of the maximum electrical conductivity and the cast iron frames served as electrodes.

To prevent the mixing of the gases by currents of the liquid, slotted hard rubber posts were placed on either side of the hard rubber plate and in these slots a large number of strips of sheet iron were supported, as shown in Fig. 2. These strips of sheet iron were insulated from the electrode frames, and, inasmuch as the electromotive force used per cell is considerably less than twice the minimum e. m. f. required to generate oxygen and hydrogen, there is no tendency for the gases to be generated upon these sheet iron strips.

The complete generator (3 cells) is shown in Figs. 4, 5 and 6. Two ½-inch gas pipes pass upward from each cast iron frame. These ½-inch pipes terminate in ¼-inch pipes, each of which contains an insulating junction and bends over and connects to one or the other of two large and slightly inclined collecting pipes, C′ and C″. These pipes, C′ and C″, connect at their lower ends to two traps, through which the liquid that is thrown over by the gases may escape; at their upper ends the pipes C′ and C″ connect to the pipes which lead the gases to the storage tanks. Connected to the bottom of each cast iron frame is a ¼-inch pipe which bends upward and terminates in a cup, through which fresh electrolyte may be introduced into the electrolytic chamber. At the bottom of each cast iron frame are two ½-inch drain pipes for use in washing out the apparatus.

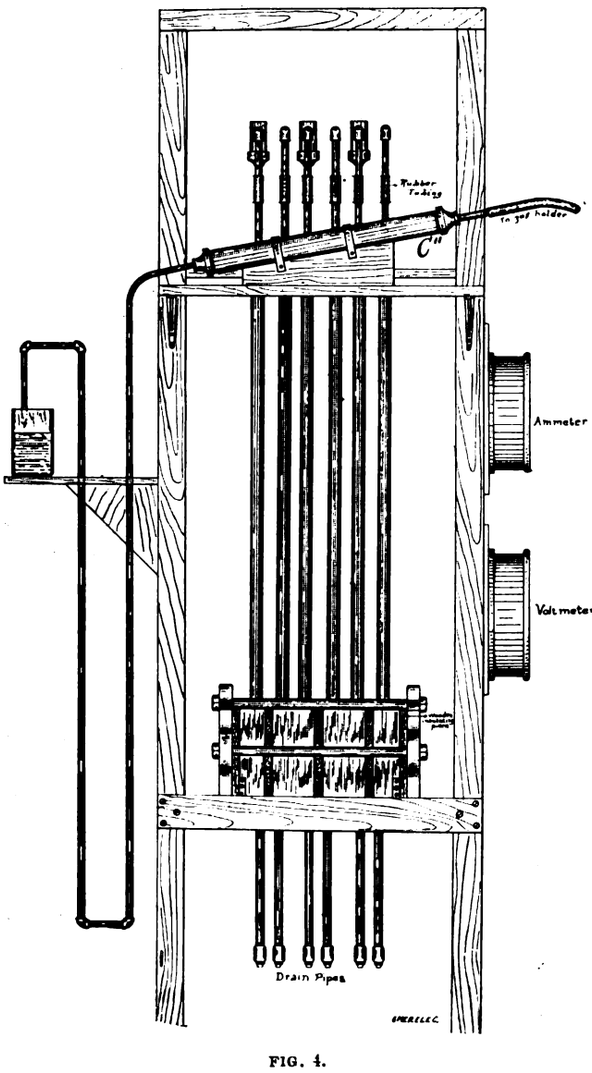

FIG. 4.

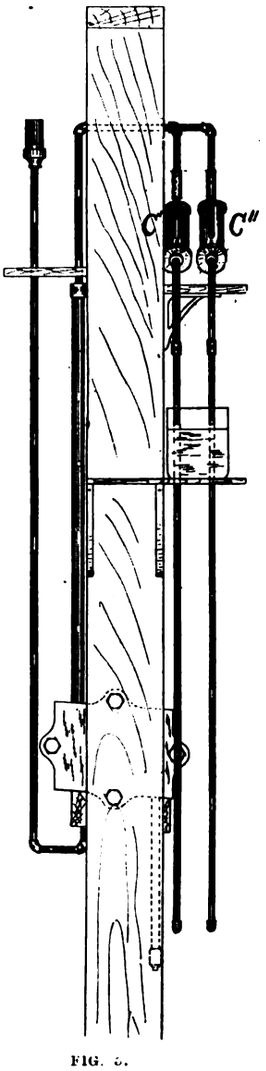

FIG. 5.

### EFFICIENCY OF GENERATION.

During the passage of one ampere for one second through an electrolytic cell .00001039 gram of hydrogen and a corresponding amount of oxygen are liberated. Now, the combustion of 1 gram of hydrogen gives 34,200 calories of heat, or 143,600 joules, so that the recombination of .00001039 gram of hydrogen with oxygen would give 1.45 joules, which is the amount of work that would be done by 1.45 volts of e. m. f. in pushing the one ampere of current through the electrolytic cell for one second. Therefore, if the e. m. f. used to push the current through the electrolytic cell were exactly 1.45 volts, then all of the work done in pushing the current through the cell would be represented by the heat value of the hydrogen and oxygen obtained and the efficiency of the apparatus would be 100%. As a matter of fact, however, the e. m. f. needed to push the current through the cell is in excess of 1.45 volts

* See Physical Review IV., 61.
† Thesis of H. J. Horn and Paul Bucher, 1898.

Digitized by Google

and the efficiency is therefore less than 100%. In fact, if E is the e. m. f. actually used to push current through the cell, then

$$\mu = \frac{1.45}{E}$$

in which $\mu$ is the efficiency of generation.

RESULTS OF TESTS.

The tests carried out by Messrs. Horn and Bucher included tests of the purity of the gases and determinations of the efficiency of generation for various rates of generation. They found the gases to be about 98% pure, the impurity in the oxygen being hydrogen and vice versa. This degree of purity leaves nothing to be desired when the gases are to be used for heating purposes. When the gases are to be used for analytical purposes in the chemical laboratory, a higher degree of purity is desirable and can be attained by increasing the distance between anode and cathode and by exercising care in the arrangement of the sheet iron strips shown in Fig. 2. For the best effect these strips should be fitted into slots in the rubber separating plate at a, Fig. 2, to prevent a downward current of liquid at a. With some care in this particular the mixing of the gases can be entirely prevented. For example, the cells which gave 98% purity, as stated above, gave 99.9 purity after a slight modification of the sheet iron strips, the hole in the hard rubber plates being made slightly smaller also.

With a current of 10 amperes the e. m. f. required per cell was 3.6 volts and the efficiency was therefore 41%. This current of 10 amperes was about as much as the cells could stand continuously without excessive heating.

The curve, Fig. 7, shows the e. m. f. required per cell for various currents and the curve, Fig. 8, shows the efficiencies of generation for various currents.

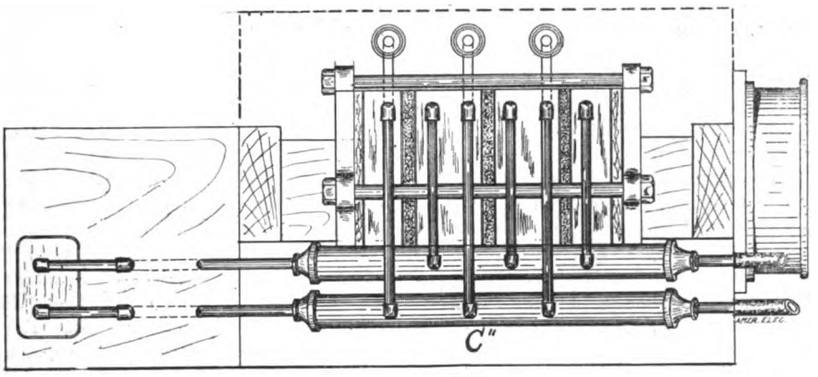

FIG. 6.—TOP VIEW.

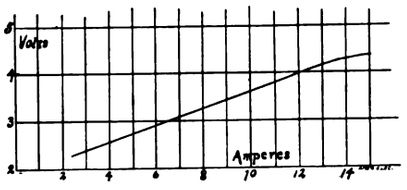

FIG 7.

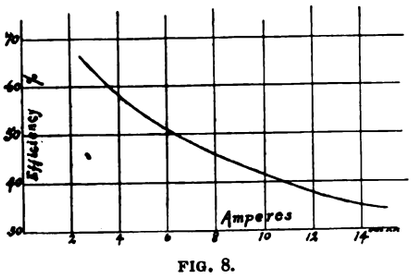

FIG. 8.

CONCLUSIONS.

The electrolytic generator here described is entirely satisfactory in every particular. There is no corrosion of the electrodes and the hard rubber withstands the action of the caustic soda perfectly. The efficiency under practical conditions is as high as 40%, and oxygen and hydrogen may be produced more cheaply by means of this generator than by any other method.

## AMERICAN TELEPHONE PRACTICE.

### COMMERCIAL WHEATSTONE BRIDGES.*

BY KEMPSTER B. MILLER.

A particular form of bridge which has come into extensive use in this country and which possesses several unique features is shown complete in Fig. 1.

The various adjustments of the arms are accomplished by placing plugs in the various holes between the brass blocks arranged in rows, as shown in the diagram, Fig. 2. Between each successive pair of blocks are arranged resistance coils having the resistances in ohms designated on the plan. Placing a plug in a hole between two blocks short circuits the resistance connected between those two blocks. The rheostat arm of this bridge is represented by the top and bottom rows of blocks and if all plugs are removed the resistance in this arm will amount to 11,110 ohms. The ratio arms A and B are represented by the left and right-hand halves respectively of the center row. A galvanometer and suitable battery, together with battery and galvanometer keys, are all mounted in a carrying case as shown.

The connections of this instrument are indicated in Fig. 2, and are as follows: The top row of blocks is connected to the bottom row by a heavy copper bar joining the right-hand blocks. This connection is made very heavy, so as to interpose no extra resistance in the rheostat. On the rheostat formed by the upper and lower rows of blocks any resistance from 1 to 11,110 ohms may be obtained, the resistance being added by leaving out plugs. The lower left-hand block of the rheostat is connected to the lower binding post, D, forming one terminal of the unknown resistance.

The upper post, C, forming the other terminal of the unknown resistance, is connected to block, X, which block is also joined to the galvanometer key. The block, R, is connected to the upper left-hand block of the rheostat. The end blocks of the middle row are connected together and to the + terminal of the battery. The — terminal of the battery is connected through the battery key to the lower left

FIG. 1.—A COMPLETE WHEATSTONE BRIDGE.

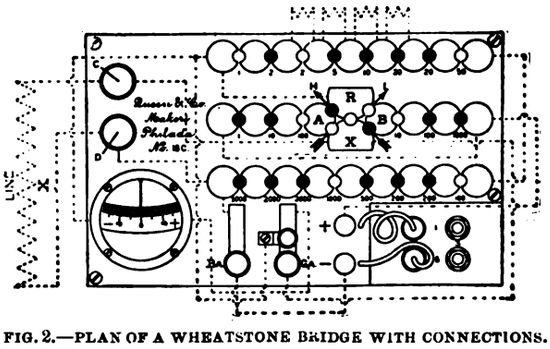

FIG. 2.—PLAN OF A WHEATSTONE BRIDGE WITH CONNECTIONS.

*From a book to be published by the American Electrician Company.

Digitized by Google

hand end of the rheostat. One galvanometer terminal is connected directly to the block, R, the left-hand block of the rheostat, and to the back contact of the galvanometer key. The other galvano-

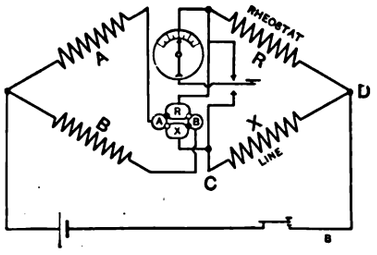

FIG. 3.—DIAGRAM OF BRIDGE SHOWING REVERSING COMMUTATOR.

meter terminal is connected through the key to the block, X.

By carefully following out these connections it will be apparent that the parts as connected form three arms of a Wheatstone bridge, the fourth, of course, being the unknown resistance joined to the line posts. This is shown diagrammatically in Fig. 3, where the corresponding parts are similarly lettered.

It will be noticed that this latter figure is practically the usual diagram, with the addition of the center blocks, A, B, X, R, forming a sort of commutator. The object of this arrangement is to make it possible to reverse the connections of arms, A and B, with R and X.

The bridge arms, A and B, have not the same range of resistances in this bridge, A having only 1, 10 and 100 ohm coils, while the resistances of B are 10, 100 and 1000 ohms. Therefore, if a ratio of 1000 to 1 for measuring large resistances is desired, the plugs are inserted in the commutator as shown; while an opposite arrangement of the plugs in the other holes will give a ratio of 1 to 1000 for very small resistances. In this bridge the galvanometer key is so arranged as to short-circuit the galvanometer while the key is up.

The galvanometers usually furnished with the complete bridges consist of a needle so mounted as to swing freely in a horizontal plane. This needle is given a tendency to point in one direction sometimes by the action of the earth's magnetic field and sometimes by the field of a powerful permanent magnet. By causing the current through the bridge wire to flow through a coil, either stationary and surounding the needle, or movable and carried on to the needle, the needle is caused to swerve from its normal position and to place itself at right angles to the lines of force due to the permanent field. The deflection of the needle is great or small, according to the strength of the current, and to the right or left according to the direction of the current.

In many of the tests to be described later a galvanometer of greater sensitiveness is required, and some form of reflecting instrument is used. In these the needle carries a small circular mirror, which reflects a spot of light from a lamp on some other source against a scale. In this arrangement every movement of the needle causes the spot of light to move along the scale, and a little consideration will show that the angle through which the reflected ray of light moves is double that through which the needle travels. Thus this reflected ray of light serves as a needle of any desired length, and has the advantages of magnifying the angular movement of the needle to twice its real amount, and of possessing no mass, and therefore no inertia.

The two galvanometers used to the greatest extent for quantitative measurements in practical work are the Thompson and the D'Arsonval.

The Thompson galvanometer is made in a great variety of forms. The needle consists of several very light bar magnets arranged side by side and with opposing poles together, so that the directive influence of the earth's field shall be very slight. The needle is directly attached to a small silvered glass mirror, and is suspended within the coil or coils by means

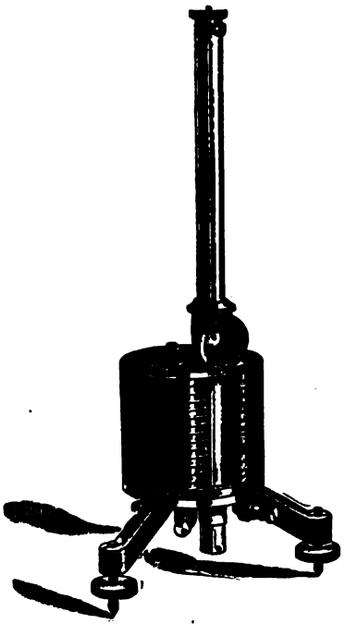

FIG. 4.—A D'ARSONVAL GALVANOMETER.

of a silk or quartz fiber. The current to be measured is passed through the coils, and the magnetic field set up thereby causes the needle to swerve from its normal position. The Thompson galvanometer is used in the most delicate tests, and is essentially a laboratory instrument. It has the disadvantage of being affected to such an extent by external magnetic fields as to render its use impossible in many cases. A passing street car or variations in the current flowing in a neighboring circuit will cause the needle to swing violently, thus making accurate work out of the question. These disadvantages may be overcome to some extent by inclosing the galvanometer in a heavy iron case—such as an old safe—but they tend to make it a very undesirable instrument for portable work. Where the instrument can be permanently set up and properly guarded, it is unequaled for delicacy and accuracy.

For nearly all practical engineering work, the D'Arsonval galvanometer is sensitive enough, and has the alvantage of being much more convenient for general work. In this the needle is a coil instead of a permanent magnet, and is suspended within the field of a powerful permanent magnet instead of a coil. The needle carries a mirror, as in the Thompson instrument. The current to be measured is passed through the coil, and as this coil lies in the field of the permanent magnet, a rotation of the coil ensues, the action being identical with that which causes the armature of an electric motor to revolve.

In Fig. 4 is shown a much used form of D'Arsonval galvanometer made by Queen & Co., Philadelphia. The field is built up of a number of horizontal permanent magnets, between the poles of which is suspended the needle.

The great advantage of the D'Arsonval galvanometer is that it is unaffected by variations in the external magnetic field. It may even be used close to dynamo machinery, without being sensibly affected.

In order to read the deflection produced by a current, in any form of reflecting galvanometers, two methods may be employed. One is to cause the needle to reflect a spot of light from a stationary source, upon a horizontal scale, and by watching the movement of the spot the number of scale divisions deflection may be accurately determined. Another and better way is to focus a telescope on the mirror, in such manner that the horizontal scale will be visible in the telescope. The mirror in its movements will reflect different portions of the scale into the telescope, and the deflection may thus be observed with great precision. When this method is used the numbers on the scale should be reversed, in order to appear normal in the telescope. Fig. 5 shows a telescope and scale as arranged for this purpose.

Complete testing sets, containing reflecting galvanometers, bridges, batteries, keys and other accessories, are frequently mounted in one case, and so arranged as to fold within small compass when not in

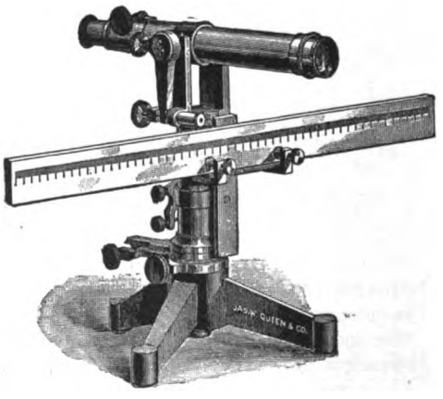

FIG. 5.—A TELESCOPE AND SCALE FOR GALVANOMETER USE.

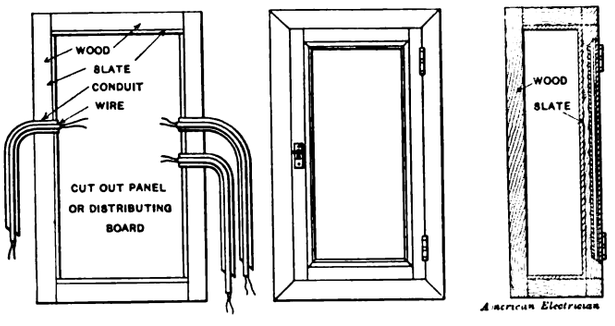
Digitized by Google

use. This arrangement is very convenient, but has one disadvantage—the manipulation of the keys and plugs jars the box to such an extent as to make the readings on the galvanometer unreliable. The separately mounted galvanometer is, therefore, in general, to be preferred. Of course this applies only to reflecting galvanometers.

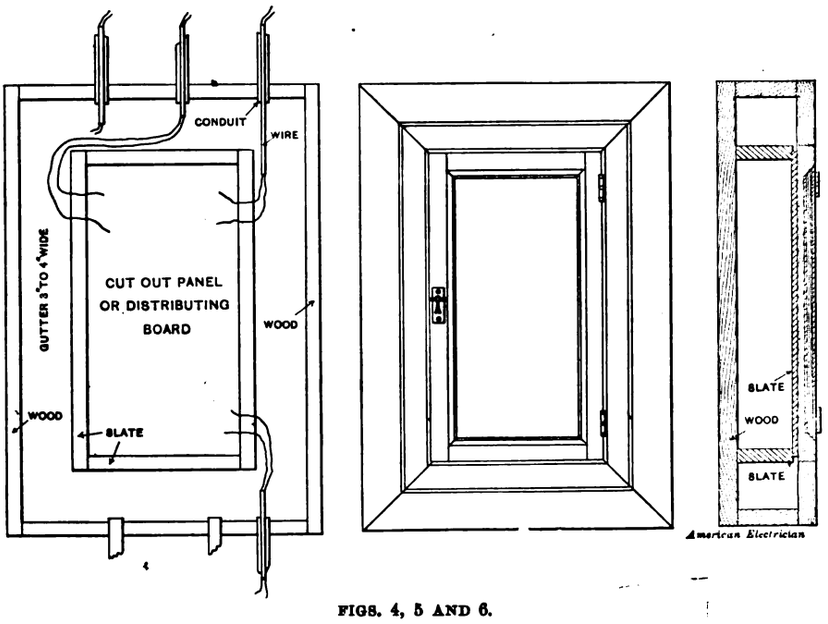


## INTERIOR WIRING.

BY CHARLES E. KNOX.

### CUT-OUT CABINETS.

In hardly any other branch of interior wiring have so great improvements been made as in the method of protecting the branch and main circuit wires by fuses. This improvement has been not so much in the direction of the fuse itself, as the method of inserting the fuse in the circuit and in making connections at the points where the conductors were interrupted or reduced in size, to place the fuse in circuit.



In former days the Edison porcelain plug fuse was used almost exclusively for the purpose of protecting circuits from overload. This fuse plug was not as bad as the outfit of which it formed a part. The fuse was self-contained, easily replaced (when one blew out) and had the advantages that all enclosed fuses have. The fuse blocks of which these fuses formed part were very inadequate for the purpose. The first ones were made with wooden bases; these were followed by porcelain blocks of the same style and design. In both cases the connections with the wires were made by screw contacts. With small sizes of wires this was not objectionable, but with the larger sizes of wires the contact was very poor. Where stranded wires were used, two or three strands would be in contact and the rest would be spread out, carrying little or no current. No attempt was made to enclose the fuse blocks or the wires. A piece of mica was placed over each block to cover the wires and contacts, but this generally disappeared after the block had been in use for a short time.

FIGS. 1, 2 AND 3.

The first great improvement was made by the introduction of the panel type of cut-out distributing boards. This consisted of a slab or tablet on which were mounted bus bars and connecting bars for making the connections between the main wires and the branch circuit wires. In these boards fuse wire was used instead of the fuse plugs. All the connections in these early panel boards were made at the back of the board—a method which was as dangerous as it was inconvenient. This type was soon followed by tablet or panel boards having front connections for all the wires. Then followed the present type of cut-out in which the fuse is "removable," i. e., the fuse is contained in a movable block having contacts at each end between which the fuse is connected. In case the fuse is blown the whole block may be removed and replaced by another one and the fuse in the first one replaced at leisure.

All the panel type of cut-outs are now installed in a wooden box or cabinet. We will, in the present number, discuss this cabinet, the method of bringing the conduit and wires to the cabinets and the means used in making the connections. In the next number we will discuss the panels or distributing boards themselves.

FIGS. 4, 5 AND 6.

The first cabinets consisted of a simple box of general form and design, shown in Figs. 1, 2 and 3. The panel was screwed to the back of the box. The sides and door of the box were usually lined with asbestos paper. With this type of cut-out cabinet (called the single box) it is necessary to bring each conduit and wire opposite the point at which it connects with the panel. This is very objectionable for the following reason: As the conduit tubes all come from the floor or from the ceiling, it is necessary to make bends or put elbows in the conduits in order to bring them to the proper points at the sides of the box. This makes an expensive piece of work and also makes it necessary to cut the partition or wall in which the cabinet is placed.

With the double type of cut-out cabinet shown in Figs. 4, 5 and 6 it is not necessary to bring the tubes at any particular point, as provision is made whereby the wires may be brought to the proper point. The means for doing this consists of a compartment (called a gutter) between the outer wooden box and the inner slate box. In this space the wires may be run, from the point where they leave the conduit to the point where they enter the slate sides of the inner box. The advantages of this method are obvious. As seen from the drawings, the door only opens on the panel, the "gutter" being covered by the trim of the box, which is fastened in place by wood screws. Whenever it is necessary to get at the wires between the conduits and the slab, it is only necessary to remove the trim of the cover. This method has now been in use for several years and has given better satisfaction than anything else yet devised for the purpose.

## BOILER CLEANERS OF THE BLOW-OFF TYPE.

It has always been a difficult problem the keeping of oil, grease and earthy matter from accumulating in steam boilers, and probably the surface and bottom blow-offs are about as efficient as any other apparatus ever devised for that purpose. The surface blow-off has been improved and added to by many engineers and inventors, for the purpose of adding

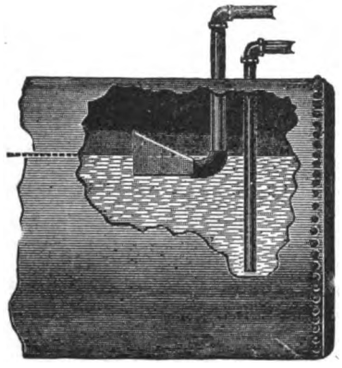

FIG. 1.—TRIUMPH BOILER CLEANER.

to its efficiency, but it still remains a surface blow-off, although it is in an improved form.

The succeeding illustrations present some of the best known forms of boiler cleaners; or "improved surface blow-offs," as they may well be designated. While these cleaners are designed to clarify all the water that is pumped into the boiler, other forms are designed only to abstract oil and grease from the water of condensation that is to be returned to the boiler. Closely allied to this type of grease extraction is the steam separation which is used for separating from the passing steam any water of condensation. In some cases there is little difference between the steam separation and the grease extraction, and in a number of in-

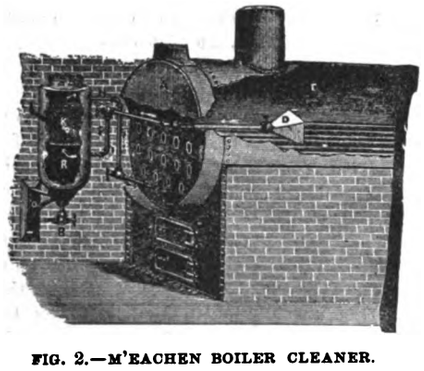

FIG. 2.—M'EACHEN BOILER CLEANER.

stances the same appliance is used for both operations, the apparatus being termed "steam separator, grease extractor and exhaust head." Nearly all water catchers may also be used for extracting grease, but as the duty of one is manifestly between the boiler and engine, and the other in the exhaust pipe, there should be some difference in construction to ensure the best results.

The boiler cleaners are several in number, and all work upon nearly the same principle—that is of a skimming dish placed at the water level. Fig. 1 shows the arrangement very clearly; this cut represents the Triumph Boiler Cleaner, made by S. W. Baid, St. Louis, Mo.

In this cleaner, as in nearly all others, the water is drawn from the water line, passed through a settling tank and then returned to the boiler again. The mechanical power necessary to circulate the water as above is taken from the energy contained in the boiler itself. A closed tank, somewhat resembling an ordinary heater, or a hot-water tank as attached to the kitchen range, is connected as shown by Fig. 2, which also represents a form of the McEachen boiler cleaner, as attached for use in water containing mud, vegetable matter and oil. A filter is shown in the settling tank, and the foreign material is separated from the water therein. But the action of the apparatus thus arranged is very slow, and the circulation is not as good as in the improved forms of this boiler cleaner, which are illustrated by Figs. 3 and 4. The arrangement of the filter, shown in Fig. 2, makes the operation of the device necessarily very slow. This has been modified in another form of cleaner, by the same maker, as shown by

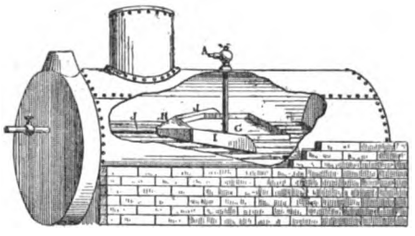

FIG. 4.—M'EACHEN BLOW-OFF CLEANER.

Fig. 3. Here the principle is clearly shown which causes a circulation of water through the cleaner. Hot water flows through the skimming dish and connecting pipes to the settling chamber. There the body of water becomes cooled through radiation of its heat, therefore it becomes heavier and forces itself back through the connecting pipes into the boiler again and below the water line plainly by the action of gravity.

This simple form of cleaner has the usual "skimming dish" at the water line, and it also has a number of pans arranged in a conical pile in the steam space. The feed water enters the upper pan and trickles down over the rest of the pans, becoming very hot in its passage through the steam space. This form of cleaner is especially desirable, for only sulphate of lime, iron, salt and other minerals which form into scale when heat is applied are found in the water.

Still another form of this cleaner, and a very simple form too, is shown by Fig. 4. In this arrangement the settling tank is dispensed with, the pans are removed and the feed pipe is brought down directly into the shallow pan, which is connected with the "skimming dish." The device is used merely as a surface blow-off, but only matter contained in the pan can be blown off unless the water is at too high a level in the boiler. This arrangement is for mud, magnesia, vegetable matter and oil. Where only these substances are contained in the water, the device shown by Fig. 4 may be used to advantage.

Trouble has been experienced, in using surface skimmers because of the varia-

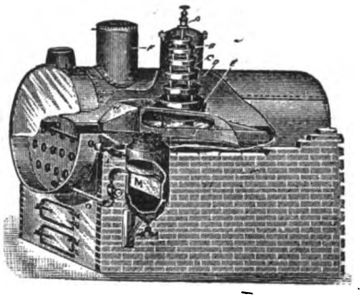

FIG. 3.—M'EACHEN CLEANER WITH PANS.

tion in the water level. The cleaner, illustrated by Fig. 5, is so constructed that it will not be drowned one minute and located high and dry the next. This is done by making a "three-story" skimmer, as shown in the engraving in question, so that as the water level varies, the upper, lower or intermediate skimmer may be in position for active service. This cleaner is sold by Foster, Hester & Co., Chicago.

One of the earliest forms of boiler cleaners of this type is that shown in Fig. 6, and made by Mr. Jas. F. Hotchkiss, New York City. In this cleaner, as in the others described above, the skimming device or funnel is connected with a reservoir outside of the boiler, in which reservoir or settling basin the material collected from the surface of the water in the boiler is deposited, but the cleaner differs from those above described in that

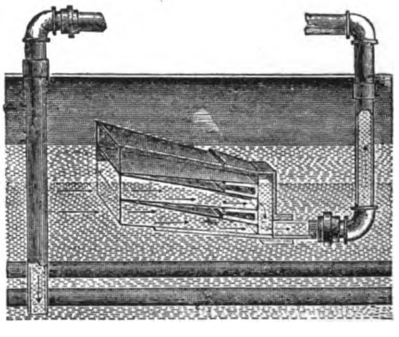

FIG. 5.—BROWN MECHANICAL CLEANER.

its arrangement is more simple and compact. The reservoir is placed immediately on top of the boiler, making the piping short and the radiation and waste of heat small. With the rest of the boiler this reservoir or settling chamber and the piping to it may be covered with heat insulating material, the circulation continuing

Digitized by Google

and apparently not depending upon the cooling of the reservoir.

Of the parts shown in the illustration, B is the settling chamber, which is spherical in shape and rests directly upon the boiler shell, A A. The circulation is maintained in the direction of the arrows from the funnel or skimming device, C, through the uptake, D, and down through pipe, E. The chamber, B, is crossed by a diaphragm, G, which compels the water

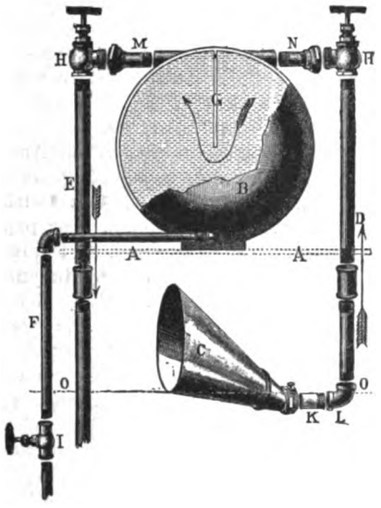

FIG. 6.—THE HOTCHKISS BOILER CLEANER.

to pass downward around it. The low velocity due to the increased cross section of the lower half of the chamber compared with that of the pipes permits the water to deposit any solid particles in this chamber. In the upper part of the diaphragm is a small air hole provided to start the circulation, the water of the boiler absorbing the air of the reservoir and filling the latter automatically when the boiler is newly put in service. F is the usual blow-off pipe for removing the deposits.

## THE EFFECT OF HEAT ON BABBITT METAL.

Almost any solid metal for lining bearings is called by the name "Babbitt metal," while in fact few of the soft linings used have any claim whatever to that title. The genuine alloy which was compounded by John Babbitt and which bears his name, is composed of eight (8) parts regulars of antimony (regular means the pure, refined metal), four (4) parts copper and ninety-six (96) parts of tin.

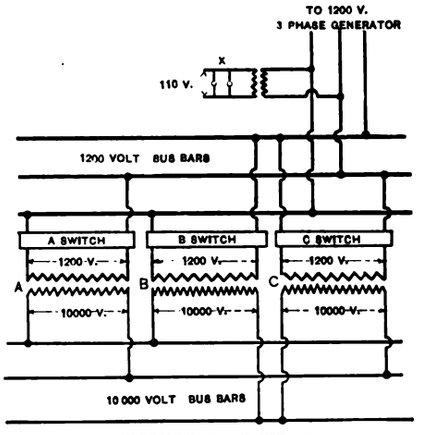
Ordinary soft lining, so-called "Babbitt metal," frequently is made up of four (4) parts lead and one (1) part antimony. Old type metal is also used for lining and consists of two (2) parts lead, one (1) part tin and one (1) part antimony. Britannia metal (pewter) is also much used for lining, and this consists of nine (9) parts tin and one (1) part antimony.

It will be noted that all the alloys above described are partly of antimony, and also contain either lead or tin, both easily oxidized metals. But antimony is even more easily oxidized and will burn in the open air if too highly heated, much like zinc. Thus, when either of the alloys described above are frequently heated, the different metals become oxidized, but burn out in different ratios to each other, thereby changing the nature of the alloy to a certain extent each time it is heated.

Genuine Babbitt will probably change its form more by re-heating than the alloys of antimony and lead, but the latter are reduced the most in quantity. The reason therefor is that the copper and tin oxidize more slowly than the antimony, which quickly burns out, leaving the Babbitt much softer than it was before getting rid of some of its antimony. Lead oxidizes much more freely than either copper or tin, therefore the alloy retains more nearly its original composition when a quantity is burned off or oxidized, still the antimony burns out faster than the lead, reducing the hardness of the alloy, but not to the extent it does when mixed with tin and copper.

Under proper conditions any kind of Babbitt metal may be melted and even kept indefinitely in a molten condition without oxidization, or, in everyday language, wthout the forming of dross on the surface of the molten metal. To secure this result protect the metal from the atmosphere. A layer of dirt on top of the molten metal will do it; even a layer of oxide or dross is a good preventive; therefore do not skim off the layer of oxide as fast as it forms, but let it stay on top of the hot metal.

A very good way is to cover the metal in the ladle or melting pot with pulverized charcoal. Carbon largely retards the process of oxidization, and if some salt and soda (common washing or cooking soda) be added to the coarsely powdered charcoal, the oxide will be reduced; that is, the dross will be smelted back into the metal again.



Another great preventive of oxidization of Babbitt metal lies in not heating the metal too hot. For all except very small bearings, where the layer of metal must run very thin, there is no need of heating the metal very hot. Just hot enough to barely char a dry pine stick is a good rule to follow when heating Babbitt metal. But whittle the stick every time the metal is tested, so a fresh wooden surface is exposed thereto.

## A Polyphase Puzzle.

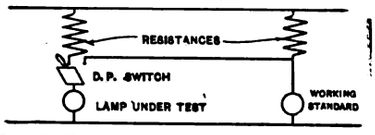
*To the Editor of American Electrician.*

Sir—The accompanying diagram of circuits illustrates an electric puzzle with which I had to contend some time ago. An 80-h. p. synchronous motor was temporarily used as a generator and connected to the three upper wires running to the 1200-volt bus bars shown in the accompanying diagram. Three 75-kw. step-up transformers connected these bus bars with three 10,000-volt bus bars connected to a high-tension transmission line, but at the time the puzzling conditions arose the switches to this transmission line were open and there was no other connection to the 1200-volt or the 10,000-volt bus bars. To one phase of the 1200-volt system a 20-light transformer, shown at X, was connected and was used for lighting the transformer sub-station. Each step-up

A POLYPHASE PUZZLE.

transformer was supplied on its low tension side through a double pole switch, these switches being shown at A, B and C. With these switches all open we obtained no light at X and one closed gave the same result. With another switch closed the lamps came up to full voltage while with the three switches, A, B and C, all closed, or any other combination than those mentioned above, the lamps came up to approximately half their proper candle power. We discovered afterward that one of the fuses of the temporary generator was out. The problem arises which fuse was out and which switches gave the different results named.

F. B.



## The "Same Circuit" Method of Incandescent Lamp Photometry.

*To the Editor of American Electrician:*

Sir—In an article upon the above subject, appearing in the last issue of your journal, I notice you mention the care that must be taken when turning off the lamp under test to prevent the diminished drop in the rheostat feeding the lamps from overburning the working standard. In practice a much more satisfactory arrangement than that shown in your diagrams has been developed, which consists in the use of two separate resistances, one for each lamp, and connected in series with that lamp as shown in the accompanying figure. If, then, one lamp is turned off, the voltage on the other one is not changed. The drawback to this method is that incandescent lamps, although supposed to be similar, are not exactly identical in resistance.

Digitized by Google

Therefore this method of working would introduce an error wherever the resistances of the lamps departed from the average, due to the fact that the drop in one resistance would vary while that in series with the working standard would remain constant. This can be compensated for by putting an equalizer wire between the lamp terminals and arranging

THE CONNECTION OF TWO RESISTANCES AND AN EQUALIZER FOR THE "SAME CIRCUIT" METHOD OF PHOTOMETRY.

to have the circuit through this wire broken at the time the lamp being measured is removed from the socket.

In central station work this can be done by means of a double-pole switch as indicated in the diagram. In case rapidity in the measurement of a large number of lamps is desired, the insertion of the lamp to be tested can be made to close the equalizer wire circuit automatically and open it again when the lamp is removed.

S. E. Doane.

Marlborough, Mass.

## Floor Outlets in Large Offices.

*To the Editor of American Electrician:*

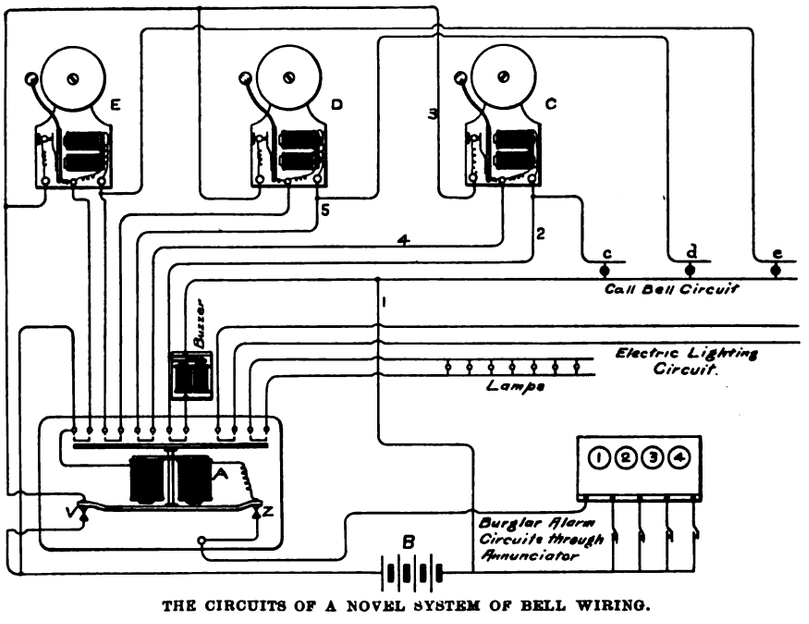
Sir—I notice an editorial in your issue of October in relation to floor outlets in large offices. Some time ago there was designed by officials of this company a floor trough which seems to answer so admirably the purposes of accommodating telephone, buzzer and other signaling conductors that a description of it may be of interest at this time.

Telephone, telegraph, ticker, bell wires, etc., can not be laid out in advance, as the requirements of future occupants of offices in respect to such service can not be foreseen, and each occupant is liable to want something different from that which his predecessor had. To reach all parts of a room with invisible wiring, and at the same time avoid tearing up floors whenever an installation or a change is desired, small wooden troughs have been used in the new building of the Chicago Telephone Company, now in the course of erection. These are placed immediately under the floors every four or five feet and running entirely across the room. At the ends of these troughs means are provided for bringing up the wires, which can also be reached at any point out in the room by boring a hole into the floor.

Connecting with the ends of these troughs there is provided around the base of the walls molding in which the wires can be carried, and which can readily be removed, thus uncovering the entrances to the wire ducts. To take the vertical wire-runs, a conduit is placed in a shaft of the building and openings are arranged on each floor. The course of a circuit, then, is through this conduit to the desired floor, thence through the floor molding to the proper room, and on through the molding and floor conduit to the desired location in the room.

This provides an accessible conduit which will enable wiremen to reach a desk at any point in the room in a ready manner, and when it is placed before the floors are laid it is, perhaps, the cheapest form of conduit which can be used.

In the new Marshall Field building, where tile floors are to be laid, tin pipes are to be imbedded in the cement filling every four feet across the room. An outlet will be provided at each end of these pipes along the walls, and if necessary they can be reached at any point in the room by drilling through a tile under any desk which the occupant may desire to reach with electric service. Architects and owners will do well to remember that the provision of such inexpensive conduit will save largely in subsequent wear and tear of the floors and walls of the building.



A. S. Howard,
General Manager Chicago Telephone Company.

Chicago, Ill.

## A Novel System of Bell Wiring.

*To the Editor of American Electrician:*

Sir—After having read with interest in the July number of the American Electrician, a note on "A Novel System of Bell Wiring," I wish to describe a system which I have used for several years where-

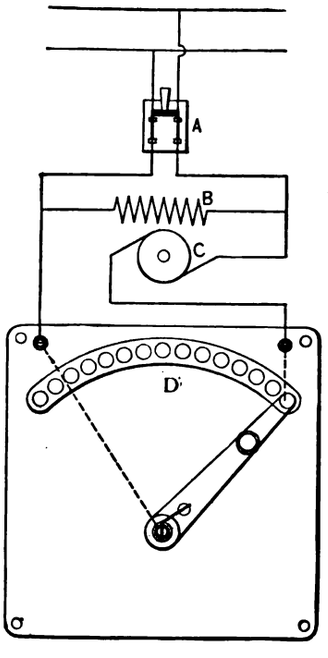
THE CIRCUITS OF A NOVEL SYSTEM OF BELL WIRING.

by all the bells may be rung together or any one may be used separately as required.

As shown in the accompanying diagram, the bells, C D E, are wired respectively as usual to the push buttons, c d e, and the battery, B. A is an electro-magnet, the armature of which carries a number of insulated contacts which when released by the closing of the burglar alarm circuit, automatically open this circuit at point, Z, and connect all the bells in series with each other, and in series with a circuit interrupter and the battery. The bells are in this combination single stroke, the make and break device on the armature of each bell being thrown out of circuit by the wires to the contacts on the armature of magnet, A. The contact, V, is closed when the armature of A is in the position shown, so that the push button circuits can return to battery through it. When working the bells in series, however, this contact must be opened in order to prevent it from short-circuiting all but bell C, when the armature of that bell is on the back contact. On the armature of A there is also a set of contacts which may be used for closing the electric light circuit if desired. With this system of bell wiring the number of wires and the number of cells of battery needed are reduced to that used in the older styles of wiring for the same purpose.

Trusting that the readers of the American Electrician may be benefited by the knowledge of such a system of bell wiring, I submit this contribution to your paper.

Bridgeport, Conn. F. M. Swalm.



[This odd system of bell wiring gives several combinations of circuits which require considerable study to discover what course the current will take under different circumstances. Apparently when the armature of magnet, A, is in the upper position and the make and break device of the buzzer begins to act current comes from the battery through wire 1, the buzzer and wire 2 to bell C, and while the armature of this bell is against the back contact finds a return to the battery through wire 3 and the contact of bell E. As soon, however, as the armature of C is attracted the current is compelled to flow through wires 4 and 5 to bell D, and when the armature of this bell is attracted it is similarly thrown to bell E. Thus the bells apparently act in succession while the contact of the buzzer remains open. This probably explains the successful use of the same battery at times on several bells in series with each other and at other times worked independently. It would require, however, a very slow acting make and break device.—Editor.]

# Electrical Catechism

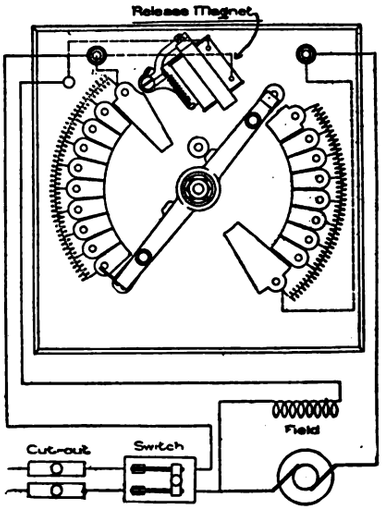
*358. How is a shunt motor started?*

A shunt motor is generally provided with two switches, as indicated in the figure. The double-pole switch, *A*, is first closed, thus sending current through the field coil, *B*. The arm of a rheostat, *D*, is then moved slowly, so as to allow a moderate amount of current to pass through the armature, *C*. As the armature begins to revolve and to come up to speed, the resistance is gradually cut out

THE STARTING ARRANGEMENTS FOR A SHUNT MOTOR.

from the rheostat, until it is all out when the arm rests upon the last button.

*359. How is a shunt motor stopped?*



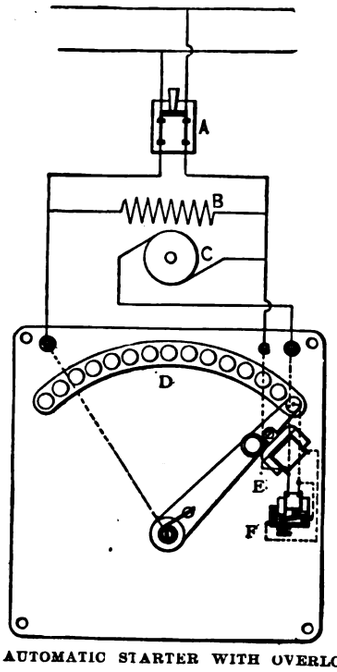
The double-pole main switch should be opened first, and as soon as the motor has come to rest, the rheostat arm should be moved back to the "off" position. If the rheostat arm is moved back first, there is apt to be vicious sparking when the last point is reached; also when the main switch is opened, there is apt to be a long arc that endangers the insulation on the field coils. Some of the automatic starting rheostats are arranged to take care of themselves so that one needs only to pull the main switch.

*360. How are automatic motor starting rheostats arranged?*

The rheostat arm carries a spring which tends to throw it back to the "off" position, also the armature of an electromagnet, whose coil is in series with the shunt field coil of the motor. As soon as the current is thrown on at the main switch, both the motor field magnet and the rheostat release magnet are energized, and the rheostat arm is magnetically held in position when it has been moved to the running position. When the main switch is opened, or the pressure is removed from the line from any external cause, the current ceases flowing around the release magnet, so that it lets go and the spring throws the arm back to the "off" position. This is called a "no-voltage" release.

*361. Why does the release magnet hold the rheostat arm after the main switch has been opened and until the motor has come nearly to rest?*

This is because the shunt motor runs in the same direction as the same machine would run as a dynamo. When the armature of the motor is revolving in the magnetic field, it generates an electromotive force just as it would if it were working as a dynamo. When working as a motor, this is in the opposite direction to that on the line, and is called a "counter electromotive force." The instant the current ceases to come from the outside source, this counter e. m. f. becomes active and sends current around through the field and through the release magnet, keeping them magnetized until the motor has fallen to a very slow speed.



AN AUTOMATIC STARTING RHEOSTAT.

*362. How are automatic motor starting rheostats arranged to open the circuit in case of an excessive load?*

They have an auxiliary magnet whose coil is in series with the motor armature. In case the current becomes greater than is safe, the "overload" magnet lifts its armature, which either trips a spring switch in the armature or main circuit, or else short-circuits the "no voltage" release magnet, which then lets the rheostat arm fly back and open the armature circuit or leave it closed through so high a resistance that it can run only very slowly. In the figure, *E* shows the "no voltage" magnet, and *F* shows the "overload" magnet in a well-known type of starting box.

*363. What causes the long flash if the armature circuit is opened before the field circuit?*

This is caused by self-induction. When the current through the magnet coil begins to stop, the magnetism begins at once to weaken. The change in the number of magnetic lines of force sets up or "induces" an electromotive force that is in such a direction as to tend to maintain the current in the same direction and at the same strength as before; the more rapid the change in the magnetization and the larger the number of turns in the coil, the higher will be the induced e. m. f. This tends to maintain the current even through the air gap as the switch is opened. In the case of a shunt machine, the e. m. f. due to opening the field circuit is likely to be many times as great as the regular working voltage, and is liable to cause a spark to jump through the insulation and either "ground" or "short-circuit" the field coil.

AN AUTOMATIC STARTER WITH OVERLOAD RELEASE.

*364. Why is the flash prevented by leaving the armature circuit closed until after the motor has stopped?*

There are two reasons; first, because the armature offers a path of low resistance for the induced current, and, second, because the armature tends to maintain the magnetizing current until rotation stops.

*365. How does the presence of a closed circuit prevent the flash?*

When the field coil is shunted by the armature or by some other path, such as a pilot lamp, the e. m. f. of self-induction from the dying down of the magnetism causes a current to flow through the coil and around through the armature or lamp circuit; this current is in the same direction as that which came from the line, and it therefore tends to keep up the magnetization. Thus, if there is a closed circuit the induced current delays the demagnetization and so reduces the induced e. m. f.

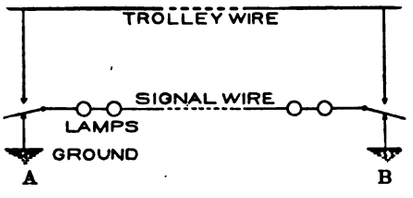
# Queries and Answers

Kindly inform me how I can change a 50 volt transformer so that I can raise the voltage from 50 volts to 100 volts, i. e., so that I can make a step-up transformer which will raise the voltage from a 50-volt circuit to a 100-volt circuit. C. H.

If the transformer you wish to change is fitted with two secondary coils which can be connected either in parallel for 50 volts or in series for 100 volts, it is a very simple matter to use them to transform from 50 to 100 volts without rewinding the transformer at all. This can be done by connecting the two secondaries in series for 100 volts and bringing out the middle point or common connection between the two coils; the 50-volt circuit should then be connected between this middle point and one of the outside wires and the 100-volt circuit can be taken off from the outside wires. The transformer will then be capable of transforming its rated load from 50 to 100 volts, even though half its wiring space, viz., that occupied by the primary, is idle. For instance, if the transformer is rated at 1 kilowatt it will transform 1 kw. from 50 to 100 volts or from 100 to 50 volts without overheating. If, however, the transformer is designed to give only one voltage in the secondary, a different means must be adopted. If this voltage is 100 volts, the simplest means is to find if possible the middle turn of the secondary winding and tap this out for a 50-volt terminal, connecting up the instrument as described above. If the transformer is only wound for 50 volts, the primary coils should be removed and another coil, an exact duplicate of the secondary, i. e., with the same number of turns of the same size of wire, should be put on in place of the primary. These two coils should be connected in series and the 50 and 100-volt circuits connected to them, as described above. In this case a transformer rated at 1 kw. would be able to transform 2 kw. In all cases the 50-volt and 100-volt circuits will be electrically connected to each other, but this is, as a rule, no disadvantage in such low tensions.



(1). Kindly let me know the system and working of signal lights at switches on single track country trolley lines.

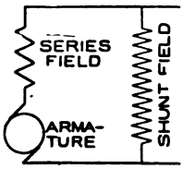
(2). What change is necessary to make direct current motors run as dynamos, and is the machine driven in the same direction as it ran as a motor?

(3). If a direct current dynamo is built to run right-handed can it be successfully run in the opposite direction, and what changes are necessary?

(4). What operation is necessary to find size or capacity of field rheostat for direct current dynamos? W. A. L.

(1). Signal lights are generally worked on one principle whereby only one extra wire is needed between the switches. The circuits are shown in the accompanying diagram, A representing the apparatus at one end of the single track line between two switches, and B that at the other end. The special signal wire between the two signal boxes is connected through two lamps in series at each end to a two-way switch, which can be thrown up to the trolley wire or down to the ground. Normally, when there is no car on the section, both switches are down or both are up and the lamps are not lighted. If, however, a car enters from the left, both switches being down, the conductor turns the switch at A into the up position, making a circuit from the trolley and through the 4 lights and the signal wire in series and to the ground at B. The lamps thus shine until this car reaches B, when the conductor throws up the switch at that point, again extinguishing the lamps. Whenever they are lighted it is a signal preventing cars from entering either end of the line. Whenever they are extinguished a car can enter from either end, the conductor invariably reversing the position of the switch at the end entered and lighting the lamps thereby. The resistance of the signal wire in series with four 110-volt lamps absorbs the full 500 volts.

(2). A direct current shunt wound motor will run as a lynamo, with no change whatever, giving at its normal speed practically the same voltage as that which it absorbs as a motor. To obtain control of the voltage a field rheostat will have to be connected in the field circuit in the usual way. A machine will only generate current when run in one direction unless its field connections are reversed, when it must run in the opposite direction. The direction to run it to make it generate is the same as that in which it runs when used as a motor.



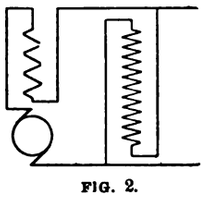


FIG. 1.

FIG. 2.

(3). A dynamo can be successfully run in the opposite direction to that for which it was built provided its brushes are radial or of any other type suitable for the reversed rotation. If not, the brush holders must be taken off and changed around in such a way as to fit the brushes for the reversed direction. All brush holders are changeable in this manner. The only change other than this is the reversal of the field magnet connections. In the accompanying diagram, Fig. 1 represents the connections for right-handed rotation, Fig. 2 represents the change necessary to adapt the machine to left-handed rotation. It will be noticed that the connections of both the series and shunt coils of the field must be changed in compound wound machines. The same change can be accomplished by simply reversing the connections to the brushes.

(4). The field rheostat of a direct current dynamo must be capable of carrying without overheating the whole of the current flowing through the shunt coils, and is usually made with sufficiently high resistance to cause a drop of 50 per cent. of the total voltage of the machine when this whole current flows through the whole rheostat. The current in the shunt field, of course, varies in different sizes of machines and varies in different makes of machines of the same size, so that no definite figures can be given for any machine without knowing its size and make. As a rule small machines lose about 5 per cent. of their total output in the shunt field, larger machines being more economical in this respect. Taking a 100-ampere 110-volt machine for example, the shunt field current would be about 5 amperes and its rheostat should have a total resistance of 8 to 10 ohms. When purchasing a rheostat the best method is to give the maker the name of the manufacturer and size of the machine. He can then decide what resistance is necessary.

We now regularly test our incandescent lamps on a photometer and with a wattmeter to see that they are of the right voltage, candle power and watts per candle. I have heard that they should also be tested to see if they are of the proper vacuum. Is this the case, and if so how should the same be carried out? W. E. J.

Yes. A lamp may show up well initially, but the vacuum is one of the most important elements of sustained candle-power and efficient life, since a slight amount of oxygen will spoil the surface of the filament and cause a great drop of candle-power. Lamps can be tested very simply in a few seconds' time by fitting up an induction coil in a dark room. The induction coil should have its secondary terminals about ¼ or ⅜ inches apart and the lamp base should be touched to one of these terminals. If there is a continued glow in the interior of the lamp the vacuum is a poor one. If there is a slight flash the vacuum is a good one. If there is no glow whatever, the vacuum is either exceptionally good or the bulb is full of air. In the latter case the lamp will soon burn out. If the filament vibrates against the glass it may give off tiny sparks, but these are no indication of poor vacuum.

What is the best manner of filling a hole between commutator bars where the mica has come out? H. A. H.

Grind up scrap mica and mix with melted shellac, not alcoholic shellac, roll into small pellets, warm these pellets until they are in a plastic condition and drive them in the hole with a short piece of wood. After the hole is filled, finish by heating with a blast lamp for an instant.

## ALTERNATORS COMPENSATED FOR INDUCTIVE LOADS.

As pointed out in an editorial on another page of this issue, alternating-current machines whenever separately excited are poorer in the quality of regulation than shunt-excited direct-current machines. Even when the alternators are composite wound they compare unfavorably with compound-wound direct-current machinery in this respect, since they are subject to a disturbing factor, inductive currents, which is not found in direct-current machinery and which destroys good regulation in spite of the composite winding. Particularly is this the case when the attempt is made to run lights and motors from the same circuit supplied by a generator not many times larger than any one of the motors.

A line of machines has been designed and is now being built by the General Electric Company to overcome this difficulty by applying a principle of excitation and regulation not hitherto reduced to practice in this country. It is really a system of compounding, but the series currents which act to strengthen the field as the load increases are not rectified but are led into the exciter and serve to raise the voltage of that machine, which in turn delivers more current to the fields of the alternator and thus maintains its excitation and resists the demagnetizing effect of its load. The advantage of the new method lies in the fact that inductive currents exert a greater magnetizing effect on the exciter than do load currents, and thus compensate for their demagnetizing effect in the main machine.

This new principle is the invention of Mr. E. W. Rice, Jr., and is claimed by him in patent No. 595,412, issued December 14th, 1897. An explanation of its action may be given by describing one or two alternating-current phenomena.

When polyphase currents are led through suitably connected collecting rings (see Fig. 1) into an ordinary continuously-wound armature, such as that of a direct-current machine, they generate in these windings a rotary field. If the armature of a machine so supplied is held stationary this field rotates with a speed equal to the frequency of supply divided by the number of poles. If, however, the armature is rotated in the opposite direction with exactly the same speed the field set up (still rotating with respect to the armature) remains stationary in space. The position which the field thus induced will assume relative to the pole pieces depends upon the angle between the coils of the armature and the coils of the generating machine supplying them.

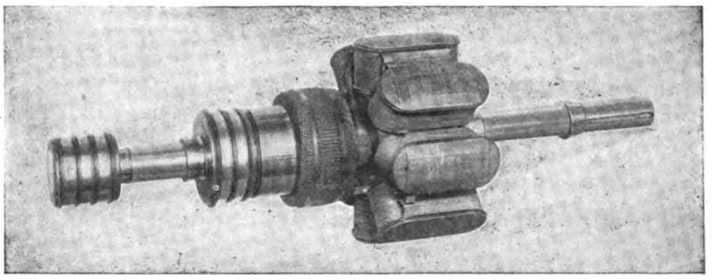

FIG. 3.—THE ROTOR OF A COMPENSATED REVOLVING FIELD MACHINE, SHOWING THE EXCITER ARMATURE AND COLLECTING RINGS.

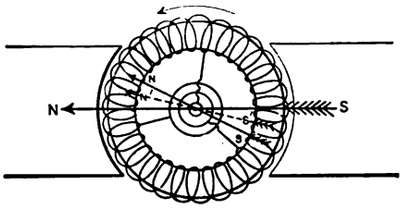

FIG. 1.—DIAGRAM OF MAGNETIC FORCES, ILLUSTRATING HOW LAGGING CURRENTS BOOST THE EXCITER OF A COMPENSATED FIELD GENERATOR.

If the armature of a direct-current machine is rigidly rotated in the direction of the arrow shown in Fig. 1 so that polyphase currents brought into it through the collecting rings set up an armature polarity, n s, as shown, this will serve to strengthen somewhat the main field, N S, of the same machine. If now for any reason the polyphase currents entering become subject to a greater inductive influence, causing them to lag, i. e., to rise and fall later with regard to the rotation of the armature than they previously did, the magnetism set up by the armature will assume the direction of the dotted lines, n' s', and will more materially assist the main field, N S, than did the previous magnetism, n s. This is the principle embodied in the machines above referred to for causing lagging alternating currents to increase the exciter voltage.

The machine shown in Fig. 1 is the exciter of an alternator and the polyphase currents brought in through the collecting rings shown are derived from the outgoing currents of the alternator by means of series transformers so that as the load of the alternator increases these currents increase and thereby give a boosting effect, n s, to the exciter field, while if the main currents lag this boosting effect is twisted around into the direction, n' s', where it still further assists the exciter field and thereby indirectly compensates for the demagnetizing action which such lagging currents exert in the armature of the alternator itself.

One of these machines, completed, is shown in Fig. 2, in which there may be seen a small direct current armature immediately under the front cover plate, a commutator and two collector rings to the left of it and three more collector rings on the extreme end of the shaft overhanging the bearing. The armature and commutator are those of the exciter, its fields having the same number of poles as those of the alternating generator itself and being enclosed immediately under the swell of the cover plate. The arrangement of the parts is made still more clear by Fig. 3, which shows the rotating element of the machine removed. Here the outwardly pointing poles of the rotating field alternator are clearly shown to the

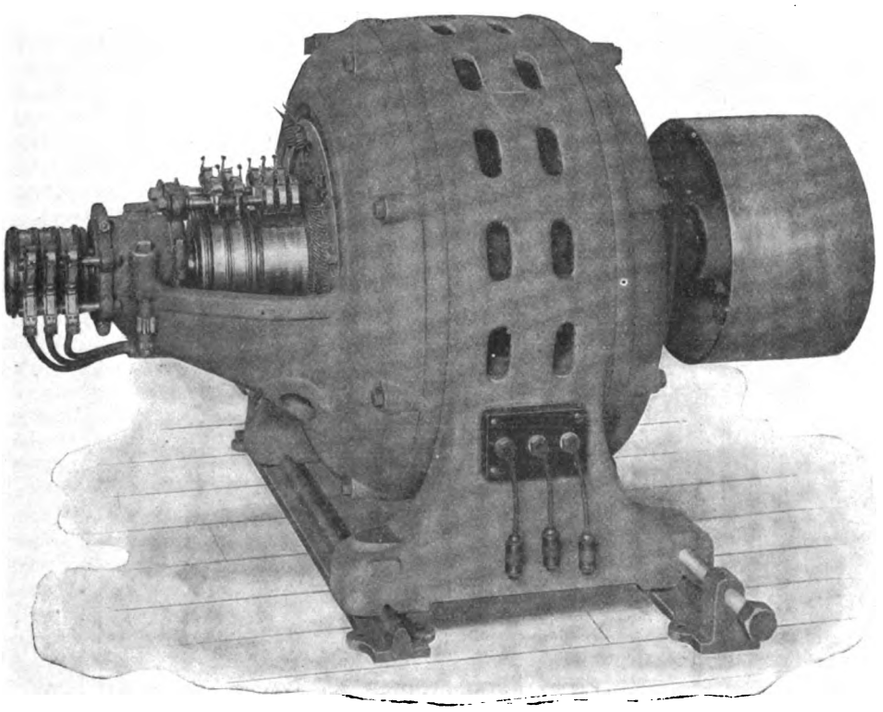

FIG. 2.—A 75-KW. 60-CYCLE, 8-POLE, 3-PHASE COMPENSATED REVOLVING-FIELD ALTERNATOR.

Digitized by Google

right; next to them, toward the left, appears the rotating armature of the exciter, with its commutator immediately adjacent to it, and to the left of this commutator are two collector rings which carry the direct current into the main rotating-field coils of the alternator. To the extreme left are three collector rings, which are tapped into the armature winding of the exciter for the purpose described above.

The connections of these parts are shown in Fig. 4, which illustrates diagrammatically the various circuits of a complete three-phase machine. To the extreme right are shown three series transformers through the primaries of which passes the main output from the armature of the alternator. The secondaries are Y-connected at their upper terminals, their lower terminals leading to the three small collector rings represented at the extreme left of the diagram, and actually at the extreme left of the machine, as shown in Fig. 3. Through these collector rings the currents from the small series transformers are carried in to the three points in the armature winding of the exciter, 120 magnetic degrees apart. In this armature they set up a rotary field which, because of the synchronous rotation of the armature in the opposite direction, becames stationary and reacts upon the exciter field as pointed out above.

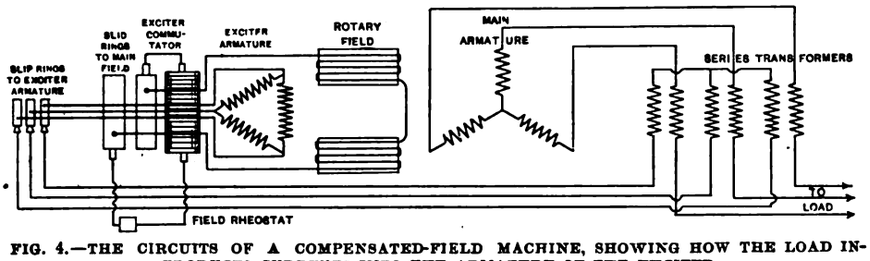

FIG. 4.—THE CIRCUITS OF A COMPENSATED-FIELD MACHINE, SHOWING HOW THE LOAD INTRODUCES CURRENTS INTO THE ARMATURE OF THE EXCITER.

This reaction boosts the regularly generated shunt field of the exciter, this boosting varying, as pointed out above, with the magnitude and lag of the main load.

From the commutator of the exciter direct current is led to the large collector rings, through which it is introduced to the main rotating field, the usual field rheostat being inserted in one side of this connection.

Machines so far developed of this type are of moderate size and belt driven, such machines being more severely taxed by the loads of induction motors of ordinary sizes than are larger direct-coupled generators. The application of the new principle allows a considerable reduction of the weight below that even of composite-wound machines of the same capacity, since the ratio of field to armature ampere turns can be reduced without sacrificing regulation, and the weight of material in the field can be reduced in consequence. For instance, one of the new compensated revolving-field alternators, with a capacity of 100 kw., delivering 60 cycles at a speed of 900 r. p. m., weighs 6800 pounds, while a composite-wound revolving-armature machine made by the same company for the same frequency at the same speed, but rated at only 90 kw., weighs 7720 pounds.

## THE HEATING AND VENTILATING SYSTEM OF A LARGE TELEPHONE EXCHANGE.

The necessity of reducing so far as possible the dust entering the operating room of a telephone exchange and settling on the enormous number of contacts of the switchboard, combined with the care

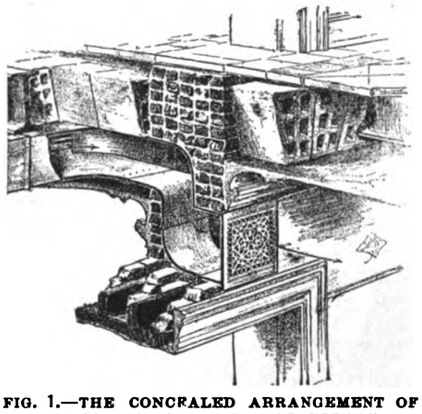

FIG. 1.—THE CONCEALED ARRANGEMENT OF THE AIR PASSAGES IN A FIREPROOF STRUCTURE.

which telephone companies find it advisable to exercise over the sanitary conditions surrounding their operators, renders the ventilating and heating system of an exchange a more serious problem than that of any other structure.

The Central Bell Exchange on Milk Street, Boston, is one of the models in this respect. The incoming air is drawn down from above the roof line by a shaft at one corner of the building, which shaft is provided with special filters for removing the dust. The air is then heated in the usual way by coils of steam pipes in the basement and blown by the fan into another vertical flue rising next the elevator shaft to branches on each floor.

The floor heights being ample in this building, there was introduced just beneath the ceiling over each floor a complete horizontal distributing system of galvanized iron pipe. The layout of this horizontal distributing system for one floor is shown in Fig. 2. While the velocity of the air in the vertical flue is high it becomes less in the horizontal mains and still less in the branches to the registers, so that the air leaves the latter at a velocity too low to cause noticeable drafts. The flues being carried under the floors and opening directly out into the rooms, the distribution is what is called overhead, the air entering warm and fresh at the top of the rooms.

The finely finished interior of such a building naturally demands that no piping be exposed to view. The corridor ceilings, therefore, over which the horizontal distributing mains run, are finished below the pipes the full width of the corridors, making thereby a false ceiling a little below the level of that of the adjoining rooms. The entire system is thus rendered completely invisible.

The arrangement of the overhead duct and its branches is clearly indicated in the illustration, Fig. 1, which shows a broken section through a partition wall and floor. The fireproof construction is evident, the building having a steel frame with hollow-tile floor arches. The registers are placed directly over the doors, and, being in interior walls, the air circulates across the rooms and toward the windows on the opposite sides.

The system was installed by the B. F. Sturtevant Company, Boston, Mass., from whose comprehensive treatise on "Heating and Ventilation" the description and the illustrations above have been taken.

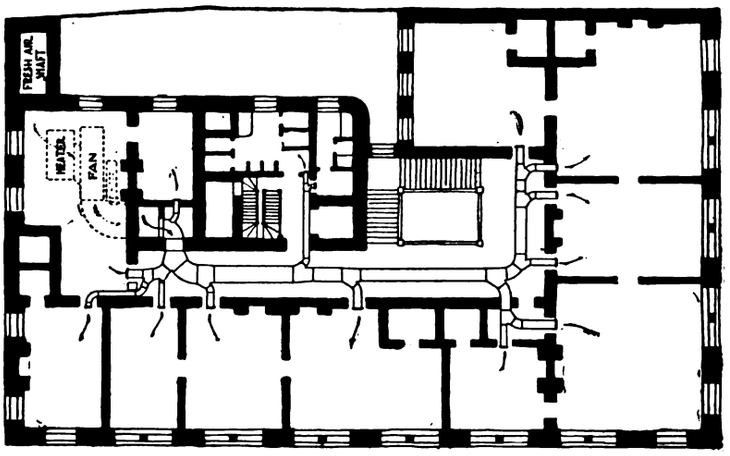

FIG. 2.—THE PLAN OF ONE FLOOR OF THE BOSTON BELL TELEPHONE EXCHANGE, SHOWING THE COURSE OF THE AIR DUCTS.

## VITRIFIED CLAY CONDUITS FOR UNDERGROUND ELECTRIC WIRES.

Ever since electricity became a recognized factor in commercial affairs, there has been a growing demand for an efficient underground construction that would protect the insulated conductors from outside influences and serve as a permanent structure into which they might be drawn or from which they might be removed without disturbing the surface of the street.

What more natural than that attention should be turned to that most common mineral, clay pottery, one as nearly indestructible as any known to man, as witnessed by the samples that were made in the earliest times of prehistoric men but which come down to us as fresh and unaltered by the centuries of exposure as they were when made.

As it was natural to turn to pottery for a material, it was equally natural that some of the existing clay working establishments should recognize this new market for their product and begin to turn their attention to the requirements in this line. Among the first to do this was the H. B. Camp Company, whose works are located at Aultman, Ohio, not many miles from Akron, which is the center of the extensive pottery industry, being in the region of extensive clay deposits.

The prevailing form of the Camp vitrified conduit is an eighteen-inch single duct length, the bore being circular and full three inches in diameter with the ends well reamed, to provide for registration when laid. The outside is square with corners chamfered off, each face being 4¼ inches wide and beaded lengthwise. Special sizes, however, are made and multiduct sections when ordered.

The work is carried on in two factories, which are about one-eighth of a mile apart, and in the vicinity of extensive clay banks from which the material is mined. Factory No. 1 has a capacity of from thirty to fifty tons of finished material per day, and No. 2 about 150 tons. The clay for No. 1 factory is obtained by surface mining, while that for No. 2 is mined from two tunnels that penetrate several hundred feet through the vein beneath the surface.

This vein is capped by an eighteen-inch vein of bituminous coal, while just above, about one hundred feet, is a five-foot vein of coal, from which is mined sufficient fuel for firing the kilns, making a very interesting fact that the fire-clay and coal in sufficient quantities to bake the clay are mined from the same bank.

From the tram cars the material is dropped into chutes and led directly into the dry pans, in which it is ground to a fine powder. These pans are about nine feet in diameter, the bottoms being of cast iron and perforated so that the material sifts through as soon as it is fine enough. The pans are revolved rapidly by means of a central vertical shaft and the pulverizing is accomplished by means of two heavy wheels held in horizontal position on a shaft, one on each side of the vertical shaft, and so attached that they move back and forth as they turn on their bearings, so as to cover the entire surface of the revolving pans. After being pulverized the material is elevated by means of bucket conveyors to the upper floors of the factory, where it is bolted, when the fine powder is delivered to bins and the coarser or unground lumps led back by means of chutes to be reground.

The tempering or moistening and kneading process follows and this is accomplished by different methods in the two factories. In factory No. 1 the pulverized material is delivered to large revolving cylinders about six feet in diameter, which rest on rollers, and, when caused to revolve, bring the material against a mixer which is attached to a shaft leading into the cylinder, water and steam in sufficient quantities being admitted to the cylinders as the process goes on. At the second factory, however, the tempering mill is like the grinding mills, the pulverized material being admitted from a chute, when an attendant directs a stream of water from a suitable pipe and watches the process and tests the mass by his hands, to determine when of a proper consistency. When suitably tempered the contents of the pan are scooped out by means of long shovels which are filled by the revolution of the mass, when it is dumped into a hopper and again elevated ready for the presses or for the forcing process.

Two types of steam presses are employed, some being vertical and others horizontal. Each consists of a steam chest about 44 inches in diameter, in which a steam pressure of about 115 pounds is employed. The piston rod is extended and carries a second smaller piston which travels in a cylinder having an opening on the upper side at one end; into this the plastic mass is directed from the chutes, after which the piston forces it into the closed end of the cylinder and the material emerges through a pair of dies at the outer end in two continuous streams, being each perfectly formed conduits, which are cut off in suitable lengths by means of wires. The ends of the tubes are then beveled off by means of a hand reamer and the sections are carefully placed on end, close together, on small platform cars which run on trucks that carry them to the drying chambers, where they are left until sufficiently dry. The time required for evaporating the moisture depends upon the condition of the atmosphere, and is usually four or five days.

After drying, the conduits are taken to the baking kilns. These are the ordinary dome down-draught kilns lined with fire brick and strengthened by means of numerous iron bands, the furnaces being arranged at suitable intervals in the outer walls of the kiln. The conduits are placed on end and piled in lengths one above the other until the entire space is occupied, when the fires are lighted, the soft coal above described being employed as fuel, and the temperature is raised to a very high degree, by stages, and then gradually reduced, the door and all openings being carefully sealed with clay. At a proper stage of the process common salt is placed upon the fires, the fumes from which serve to glaze the surface of the conduits both inside and out, rendering them smooth and practically impervious to water. The process of charging, burning and emptying a kiln occupies from four to five days, some times as high as eight, depending upon the material.

On removing the sections from the kiln they are either loaded for shipment directly on cars which are brought in on sidings along the line of the kilns, or the material is piled in great quantities in the yard, where it awaits shipment. Usually, before shipping, the inner surface is smoothed by means of a peculiar shaped scraping tool.

The Camp works were established about ten years ago and were first engaged in the manufacture of ordinary red brick, then drain tile became the principal product, after which sewer pipe was manufactured in great quantities, when electric conduits became the chief product, and on these the works are now running, although large quantities of porous floor brick are manufactured, which serve as flooring material for large office fire-proof buildings. The works are operated under the direction of H. B. Camp, who designed and built the principal machinery, and Mr. Wm. Weaver, who is superintendent and general manager of the works.

The permanence or value of clay products depends chiefly on the way in which the chemical changes are brought about during burning and the proper temperature to which the clay is subjected, and this feature should be carefully considered by all purchasers of clay products, especially those designed for underground conduit work. If, in the process of burning, only sufficient heat has been applied to drive out the water of hydration, the resulting material will be porous and friable and will crumble under the action of frost on account of its porosity and attraction for moisture. By carrying the heat above the point to expel the moisture the clay will be found to continue to shrink and grow more hard and dense and more impervious to water until finally, if stopped at the right time, the mass will have become practically impervious and very hard, strong and tough. In this condition the material is a new chemical compound, forming an indestructible mineral. If, however, the heat be continued above this most favorable point the clay begins to deteriorate in some of its qualities. There is a difference, however, in clays; some only require to be made moderately hot, while others require the highest temperature attainable in metallurgic practice. From the above it is apparent that purchasers of products of this description should know the quality of the material and that reasonable care and skill has been exercised in the manufacture of the same.

# New Apparatus and Appliances

NEW SIEMENS & HALSKE APPARATUS.

As noticed in the last issue of the American Electrician, the Siemens & Halske Electric Company of America has greatly broadened the field of its operations and taken up the manufacture of many new lines of apparatus at its works in Chicago. A description of some of this newly developed apparatus may prove of interest here.

An instrument new to the works of this company, although in a slightly different form quite familiar to the trade, is the alternating current integrating wattmeter illustrated in Fig. 1. This is the design of Mr. Thomas Duncan and resembles in its general construction the meters of the same design formerly made by the Fort Wayne Electric Corporation.

The new instrument shown in Fig. 1 is known as the improved Duncan meter. The shape of this instrument has been made higher and narrower, the impedance coils being placed in a separate sheet-iron box on the back. The convenience of hanging is greatly improved, and the case is attached to the frame with a hinge and screw, forcing it against a rubber gasket, rendering it dust proof. The meters are direct reading, with no constant, in all sizes up to and including the 100-light size, the details of the internal construction being practically the same as those

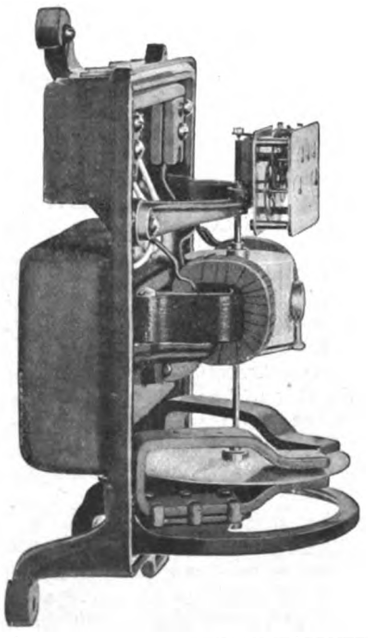

FIG. 1.—THE IMPROVED DUNCAN WATTMETER

of the older Duncan meters. In addition to the ordinary single-phase alternating meters, Mr. Duncan is developing a complete set of polyphase and direct current indicating, integrating, recording and switchboard meters, as well as ampere hour meters for both alternating and direct currents.

Another new line is that of enclosed arcs, one of which is shown in Fig. 3. This is a direct current type of high grade design, embodying a concentric coil operating a lava roller clutch acting on the carbon. The outer globe is fitted with a hole at the bottom, through which the inner globe can be lowered for trimming. This lowering also opens the circuit.

Of the 2000 automobile motors men-

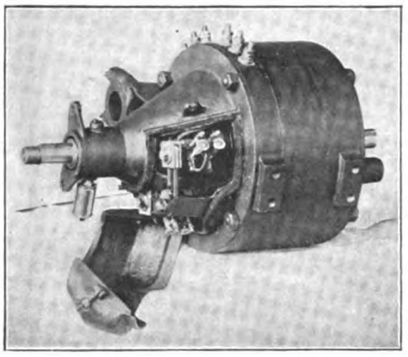

FIG. 2.—AN AUTOMOBILE MOTOR.

tioned in the last issue of the American Electrician one is shown in Fig. 2. These motors are designed to run continuously with an output at 4 h. p. and a rise of temperature not exceeding 40° C. In order to secure maximum output and efficiency

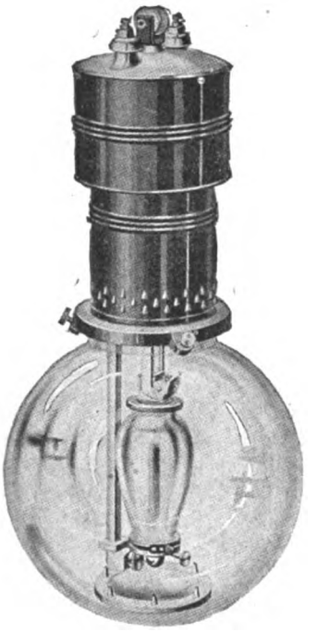

FIG. 3.—A NEW ENCLOSED ARC LAMP.

with minimum weight the entire field structure is made up of laminated iron. They are fitted with radial brushes of the type designed by Mr. A. Churchward and used by him on the motors and generators of the Excelsior Company two years ago.

A LINE OF ENCLOSED MOTORS.

The chief objection to the enclosed motor as ordinarily made is the trouble that may occur with the commutator due to worn out brushes or any other derangement, which trouble is not observable until it becomes so serious as to interfere with the motor's operation.

The Western Electric Company, Chicago, has brought out a line of "encased" machines (see Fig. 4), as the company prefers to call them, in which this objection is met by providing mica windows in the cover plates on the commutator end of the machine. The same motors may be used with these cover plates removed, in which state they are styled "semi-encased" machines, and they will, when so used, deliver a higher output than when entirely encased. For instance, a motor weighing 1300 pounds and running at 700 r. p. m., is rated at 10 h. p. with the covers off and only 7½ h. p. when entirely encased.

Both the magnet frames and the magnet cores of these motors are made of cast steel, the cores being bolted to the yokes. The end brackets supporting the bearings are fastened to the circular frames by four screws equally spaced around the circle, so that by taking out these screws and rotating the brackets either a quarter, a half or three-quarters of a turn, the self-oiling bearings may be brought right side up with the motor supported in any position; upright on the floor, inverted on the ceiling or bolted to a wall or column.

These motors are wound with either shunt or series fields or are compounded in two different ratios, one entitled "quarter compound" and the other "half compound." The term "quarter compound" signifies that one-quarter of the total volume occupied by the field coils is used for the series winding, the other three-quarters containing the shunt winding. This ratio of coil sizes gives a speed variation of about 15 per cent. between no load and

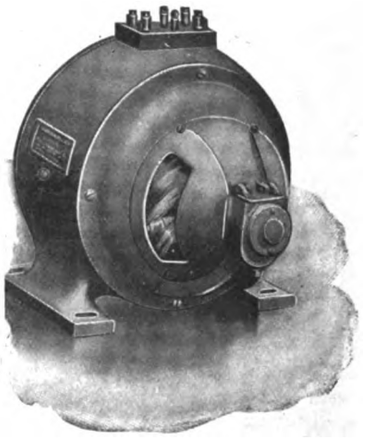

FIG. 4.—THE WESTERN ELECTRIC "ENCASED" MOTOR.

full load. In the "half compound" machines the series coils occupy about 50 per cent. of the total volume of the field windings. These motors drop about 40 per cent. in speed from no load to full load. The first machines are, of course, desirable where a nearly constant speed is desired, and the second where highly fluctuating loads are encountered and corresponding fluctuations of current are undesirable in the electric circuits.

### A PARALLEL MOTION BRUSH HOLDER.

One of the disadvantages of the ordinary form of brush holder in which the brush rocks around the rod supporting the holder is that its point of contact with the commutator is constantly changing. As the commutator surface rises and falls, due to slight eccentricities, the brush rocks back and forth, making contact at one instant under its leading edge and at the next instant under its following edge. This difficulty is overcome in the reaction brush by making its movement a sliding one, but at the expense of losing the tightly clamped construction by which the current is readily carried from the brush to the holder.

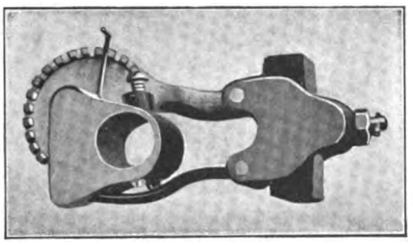

FIG. 5.—AN IMPROVED BRUSH HOLDER.

An arrangement designed by Mr. W. K. Bassford, Jr., for use on the generators built by the American Engine Company, Bound Brook, N. J., is illustrated in Fig. 5. It will be seen that in this case the brush is clamped in a holder which is supported on two links forming a parallel motion, so that as the holder rises and falls the face of the brush remains in parallel planes tangent to the commutator. The tension spring and adjusting device are of the simple and easily locked style common in reaction brush holders.

### AN ELECTRICAL SOUVENIR OF THE DEWEY CELEBRATION.

Fig. 7 shows an application of the electric scarf pin and pocket storage battery to souvenir work, the lamp being covered

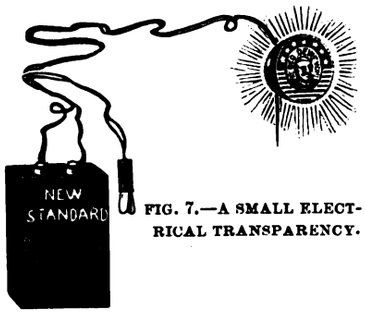

FIG. 7.—A SMALL ELECTRICAL TRANSPARENCY.

with a transparency in this case of Admiral Dewey. The combination was devised by Mr. Wm. Roche, New York City, for the recent Dewey celebration.

### A MOTOR DESIGNED FOR DIRECT GEARING TO MACHINE TOOLS.

The illustration, Fig. 8, shows a 28-in. swing screw-cutting engine lathe driven by the Bullock type N motor. As will be seen the motor is placed directly on the spindle in the head-stock, taking the place of the cone pulleys. The armature spider is built directly upon the hollow spindle of the lathe.

By means of a new system of variable speed control, the motor is given a greater range of speed, without loss of torque, than is ordinarily given by the cone pulley, having sixteen speeds in either direction, including the back gear. The controller is placed upon the leg of the lathe directly under the head-stock, and is operated by a splined shaft running along the bed of the lathe, and a handle which travels with the carriage. The slowest speed is 60 and the highest about 250 revolutions.

The motor is fully described in bulletin No. 0435, which may be had by addressing the Bullock Electric Manufacturing Company, Cincinnati, O.

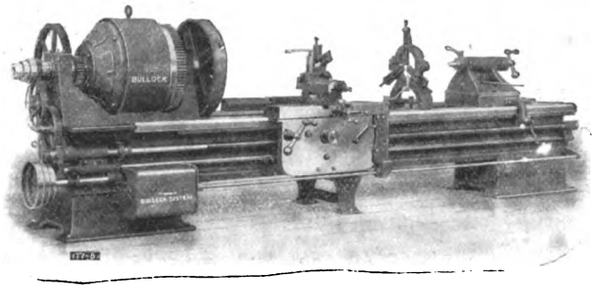

FIG. 8.—A SPECIAL TOOL MOTOR.

### SOME SMALL ELECTRIC SPECIALTIES.

Fig. 9 shows a receptacle for miniature lamps, with Edison bases, made by the H. E. Plass Electrical Supply Company, New York City. The base of the receptacle is of porcelain and the insulating material between the terminals is mica, so that it is fireproof and well adapted to exposed locations. The same illustration shows a miniature lamp made by the same company in two forms, one with a hook, making of it a watch charm and the other in scarf pin form.

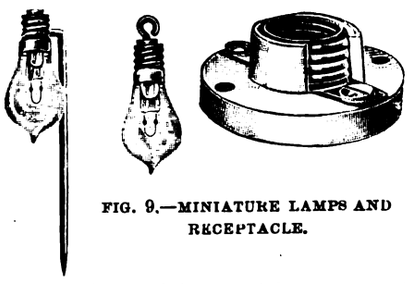

FIG. 9.—MINIATURE LAMPS AND RECEPTACLE.

### A VARIABLE SPEED MOTOR.

The customary methods of reducing the speed of a direct current motor on constant potential supply are to insert resistance in the armature circuit or to strengthen the field. The first is wasteful and does not give a definite speed regulation. The second is more economical of power but requires a large and expensive motor in order to get sufficient field strength for the very slow speeds. It also leads to trouble at the high speeds through not having sufficient field strength to saturate the poles, and therefore to give a proper commutating fringe of magnetism.

Mr. F. A. Johnson has patented a means of overcoming this difficulty by a device which is embodied in a motor now built by the Stow Manufacturing Company, Binghamton, N. Y., one type of which is shown in the skeleton illustration, Fig. 10. In this motor the field strength is varied to give the desired change of speed. The variation is not accomplished by changing the exciting current, however, but by changing the magnetic reluctance of the path of the field magnetism. This is accomplished by mechanically moving up or down a plunger, shown in the illustration, which forms the central and main part of one of the poles of the motor. Surrounding this plunger is a shell which, even when the plunger is moved to its upper limit, conducts some magnetism to the pole, giving sufficient field for the highest speed. Owing to the fact that this field does not come down the center of the pole, but at its edges, it is concentrated at the pole tips, where it is needed for giving the proper reversing tendency to the current in the coils as they pass under the brushes. Thus the movement of the plunger up or down, varying as it does the reluctance of the magnetic circuit and thereby changing the field strength, and with it the speed of the motor, does not alter materially the strength of the field just under the tips of the pole, thus giving good commutation at all speeds. In the motors, as made under this design, the upwardly extending rod from the plunger is screw threaded and fitted with a hand wheel for moving it with ease and giving it fine adjustments.

A BATTERY VOLTMETER.

Fig. 11 shows a voltmeter of the pocket watch-case style, the scale reading from zero to 3 volts in one-tenth volt divisions, designed for the indication of primary and storage batteries. The instrument is not polarized and will read when connected to the circuit in either way, thus saving

FIG. 11.—POCKET VOLTMETER.

considerable time when connecting up. It is not readily burned out and its parts are designed to stand considerable abuse so that the accidental connecting of eight or ten cells is not liable to injure the instrument. It is made by the Eldredge Electric Manufacturing Company, Springfield, Mass.

AN INTEGRATING STEAM ENGINE INDICATOR.

For the constantly varying loads of steam engines in electric light, and particularly in street railway service, the ordinary indicator gives records on which but little dependence can be placed when the attempt is made to determine the coal or water consumption or any other factor per indicated horse power hour. No matter how frequently the cards are taken, up to the capacity of the operator, it is hard to get a real average unless the length of the test is prolonged and the number of cards is enormous, entailing a great amount of planimeter work and the liability of error in tabulating the results. On this account an instrument which would automatically measure the amount of work done during each stroke and add this work to a record on a dial, so that by simply taking readings at five-minute or other intervals the number of horse power hours delivered by the engine between readings could be determined at sight, would prove a valuable appliance in power house testing.

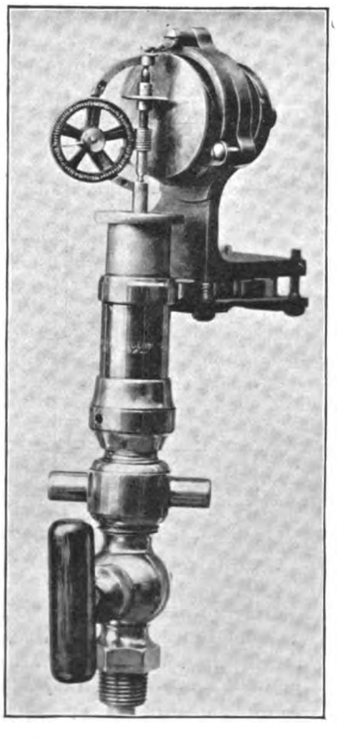

FIG. 12.—A HORSE-POWER-HOUR RECORDING DEVICE.

Several such instruments have been designed, notably abroad, but by far the neatest and simplest that has come to our attention is one devised by Mr. Benj. H. Blaisdell, Chief Engineer of the Charlestown Power Station of the Boston Elevated Railway Company. This instrument in its most improved form is shown in Fig. 12, from which it will be seen that the pencil mechanism of the ordinary indicator is replaced by a part of the recording mechanism fastened to the end of the piston rod of the indicating cylinder. This frame supports a hardened steel spindle mounted between cone centers. The spindle has secured to it a friction roller and worm, the latter engaging a pair of light worm gears also supported by the frame. One of these has 100 teeth and carries a graduated scale, while the other has 99 teeth and carries a pointer traveling over this scale. Clamped to the arm of the indicator which usually supports the paper drum is a bracket carrying a circular disc placed in a vertical plane. This disc is rotated back and forth by the usual reducing motion from the engine cross-head just as is the paper drum on the ordinary indicator, while a small helical spring serves to press the disc with a light contact against the roller on the piston rod frame.

The adjustment of the instrument is such that at atmospheric pressure the roller bears against the center of the disc and any rotation of the latter will not cause any movement of the roller. As the roller rises, however, due to steam pressure under the indicator piston, it will receive a motion of rotation proportional to the product of the steam pressure and the speed of the cross-head of the engine. On the return stroke the roller will be turned back if there is back pressure in the cylinder or will be turned further forward if there is a vacuum in the cylinder. Thus the angle turned through by the roller during any time interval will be proportional to the work done during that time, and the work done by the engine will thus be shown at all times on the graduated scale. A constant can be readily obtained for the instrument so that the scale reading can be reduced to horse-power hours and divided by the time to average horse power without the usual labor with the planimeter, the deduction of mean effective pressure, etc.

The instrument has given good results under test and will no doubt be found useful by those desiring the highest economy in engine running.

FEED WATER HEATERS AND PURIFIERS.

For steam plants located in districts where the feed water contains much lime or other impurities insoluble in hot water, no auxiliary appliance is more important than a feed-water purifier. Purifiers for such cases are very simple in principle, as they need only consist of feed-water heaters, the impurities being rendered insoluble by the heating and being deposited in the heater instead of in the boiler.

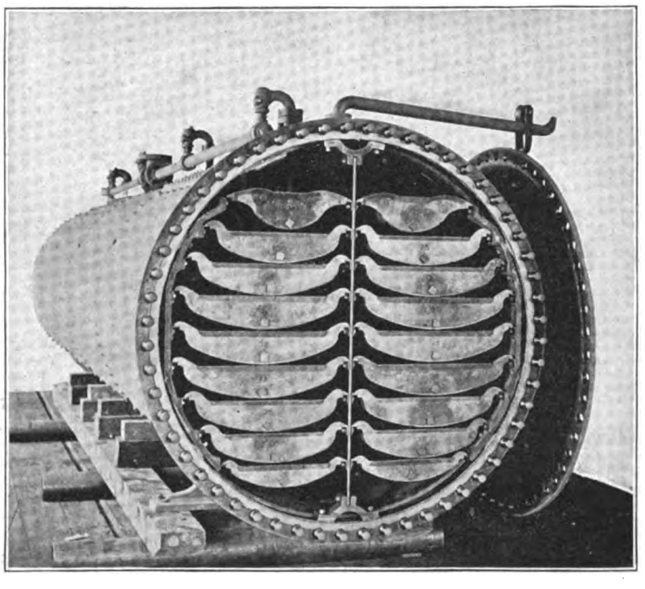

FIG. 13.—A FEED-WATER PURIFIER SHOWING PANS.

A purifier of this type, made by the Hoppes Manufacturing Company, Springfield, Ohio, is illustrated in Fig. 13, this being a live-steam purifier, the feed water being pumped into it under full boiler pressure, live steam surrounding the feed water and heating it up to the temperature

Digitized by Google

of saturated steam at full boiler pressure.

A very similar machine is made by the same makers for utilizing the thermal energy remaining in exhaust steam to heat up the feed water to 210° F., this heater resembling the purifier shown in the illustration, but having in addition an oil eliminator to prevent the cylinder oil from being returned to the boiler and a water-level regulator of the float-valve type to maintain the proper level of hot purified feed water in the bottom of the heater from which the pumps draw and feed the boilers.

The structure of the purifier shown in Fig. 13 consists of a boiler shell within which, supported by suitable ledges, is a series of shallow pans made of steel plate. These pans are so designed that when the feed water is led into the top pan it flows over the ledges in a thin film and adheres to the under side of each pan until the lowest point is reached, when it drops into the next pan, and so on to the bottom of the shell. Steam is admitted directly from the boiler in the live steam purifier and from the exhaust in the feed-water heater, heating up the thin sheets of water on the under sides of the pans, causing the water to cease acting as a solvent for the impurities which are then deposited on the pans much as are stalactites in natural caves. By removing the head of the shell the pans can readily be taken out, cleaned and returned. The head is bolted on over asbestos packing and for its removal there is provided a swinging arm or crane fitted with a trolley by which the head may be swung out of the way without the application of great force.

The live steam purifiers are made in sizes up to 1000 h. p., this size being 5 ft. in diameter and 24½ ft. in length. The exhaust-steam heaters are made up to 5000 h. p., the dimensions of this mammoth size being 68½ ins. in diameter by 26½ ft. in length.

### A SPECIAL STEAM SEPARATOR.

The accompanying cut, Fig. 14, shows a special Sweet's separator of which two are being made for the New Jersey Zinc Company by The Direct Separator Company of Syracuse, N. Y. The separator is arranged for a side inlet and top outlet and in operation is similar to the standard machines of the same make—that is, the water running along the bottom of the horizontal pipe is caught by the projecting cone A and carried back of the lining to the water chamber. The steam surrounding the central pipe B leaves more or less water adhering to its surface and this moisture traveling downward is caught by the projection C and carried through the pipe D to the water chamber. The steam in passing downward is brought in contact with separating surfaces E and F, which conduct the little particles of water from the steam current and keep them from further contact with it.

By reversing the direction of the steam current any moisture yet remaining is thrown downward to the water chamber.

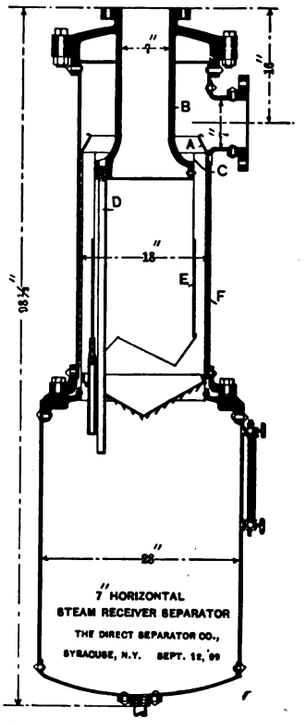

FIG. 14.—A SPECIAL RECEIVER SEPARATOR.

The separators are each made of two welded steel tubes, with flanged steel

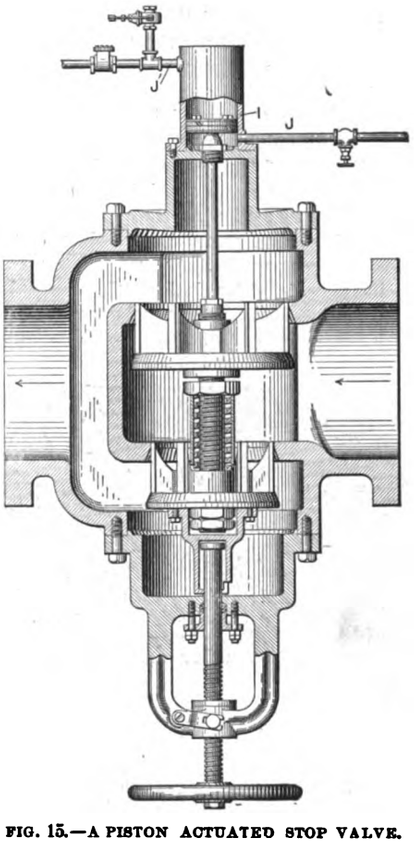

FIG. 15.—A PISTON ACTUATED STOP VALVE.

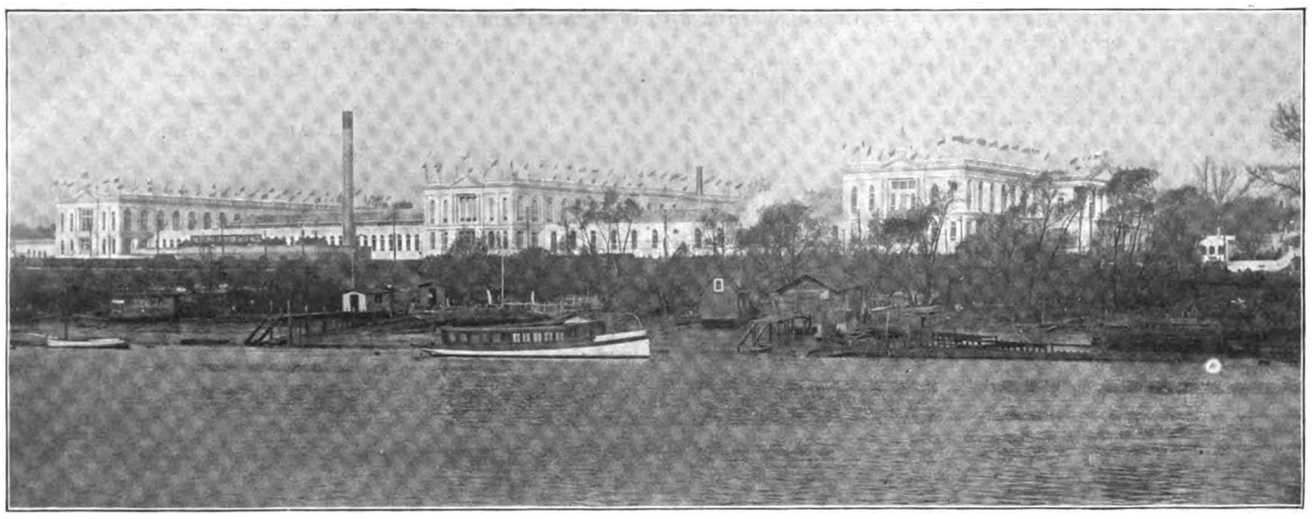
head, arranged for parting in the middle, as shown, designed for a working pressure of 150 lbs. per sq. in. The linings are of heavy gage cold rolled copper, and the other structural points will be understood from the drawing.

### AN AUTOMATIC STOP VALVE.

For the purpose of cutting off the steam from main pipes or headers in case a break occurs, several automatic valves have been designed in which the movable parts are carried to their seats by the increased rush of steam past them. Such valves must be carefully adjusted so that they will not close when the rush of steam is simply that of an overloaded engine and they are likely to stick just when most wanted.



The valve shown in Fig. 15, made by the Locke Regulator Company, Salem, Mass., depends upon another principle, viz., the drop of pressure between the boilers and the distant end of the steam line, such as the throttle. This difference of pressure is introduced into an auxiliary steam cylinder within the valve, the piston of which operates the main valve. The cylinder is shown at I in the upper part of the illustration, the pipe, J, coming from the boiler and the pipe, J', communicating with the other end of the steam line. The valve proper is of the balanced type, and, so long as there is no material drop of pressure in the steam line, remains in the open position owing to the force of gravity. As soon, however, as any break or other accident occurs, occasioning a considerable difference of pressure, the piston in cylinder, I, is forced upward, closing the valve with it. The valve can also be either opened or closed by means of the screw and hand wheel at the bottom, this screw being normally left in such a position that the valve discs are free to move from their open to their closed position. This makes it a convenient hand cut-off, taking the place of the ordinary valve in the main pipe. The valve stem is kept in alignment by means of wings on the valve seats, and a powerful spring is provided to give a relative movement between the two discs so that both may, under all circumstances, come up firmly to their seats.

## NEW BOOKS.

Construction and Repair of Commutators. By L. C. Sharp. Omaha, Nebraska: Published by the author; 31 pages. Price, $.50.

This little paper-covered reference book is intended for machinists and others who have to work with commutators in ordinary shops and desire handy rules based on the results of practical experience. The book discusses the complete construction of a commutator from the segments and sheets of mica to the finished apparatus, telling and illustrating by sketches how to straighten the segments, cut the insulation, build it to gage, assemble the parts in the compressing ring, burn out the shellac, turn to size, bake and test.

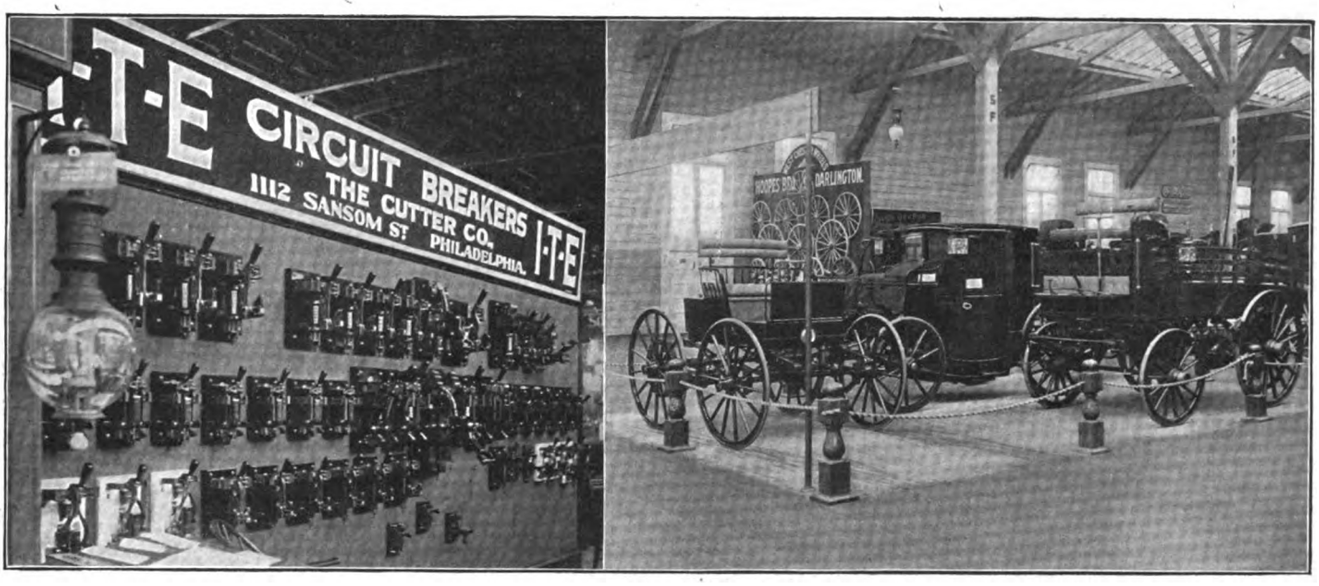
# THE NATIONAL EXPORT EXPOSITION.

During the year that has passed since the close of the war between the United States and Spain this country has virtually adopted a policy of territorial expansion which has induced a most remarkably widespread and powerful tendency toward industrial expansion. Not only have American manufacturers become alive to the possibilities of trade in the new territory brought under the protection of the Stars and Stripes, but the field which they covet has extended to much wider boundaries, and efforts such as belittle any previous attempts in the same line are being made to encourage orders from the countries of South America and the Orient as well as of Europe itself. Most timely, therefore, is the opening of an exposition unique in history in that it aims to display the products of American manufacturers for export.

The National Export Exposition which was opened on September 14th in grounds located in West Philadelphia, immediately adjacent to the University of Pennsylvania, and which will remain open until November 30th, is under the combined auspices of the Philadelphia Commercial Museum and the Franklin Institute. The purpose of the Museum is the same as that of the Exposition, viz., to promote export trade of American products, while the Franklin Institute has had experience with some thirty previous exhibitions, which experience has been a large factor in aiding the success of the present one.



The magnitude of the exposition is far from realized by those who have not visited it. An idea of its scope can be given by figures as to the financial outlay involved. The United States Congress appropriated $300,000 for the buildings, part of which are permanent in character and designed for the continued use of the Philadelphia Commercial Museum. The City of Philadelphia appropriated $200,000 for the use of the Museum and the State of Pennsylvania appropriated $50,000 for erecting and equipping the power station, which is also permanent, as well as $25,000 for other purposes. Over $100,000 was also raised by subscription. Congress also appropriated $50,000 to be expended for the purchase of samples of merchandise in foreign markets to be displayed at the exposition in order to give American manufacturers an idea of what they must meet in competition, this merchandise to become the property of the Commercial Museum.

The greater part of the exposition is housed in one mammoth main building nearly 1000x400 feet in size. This consists of three permanent pavilions of steel girder construction connected by arcades and halls of temporary construction. In addition to this building there is a separate structure for the vehicle and furniture exhibit and another for transportation exhibits.

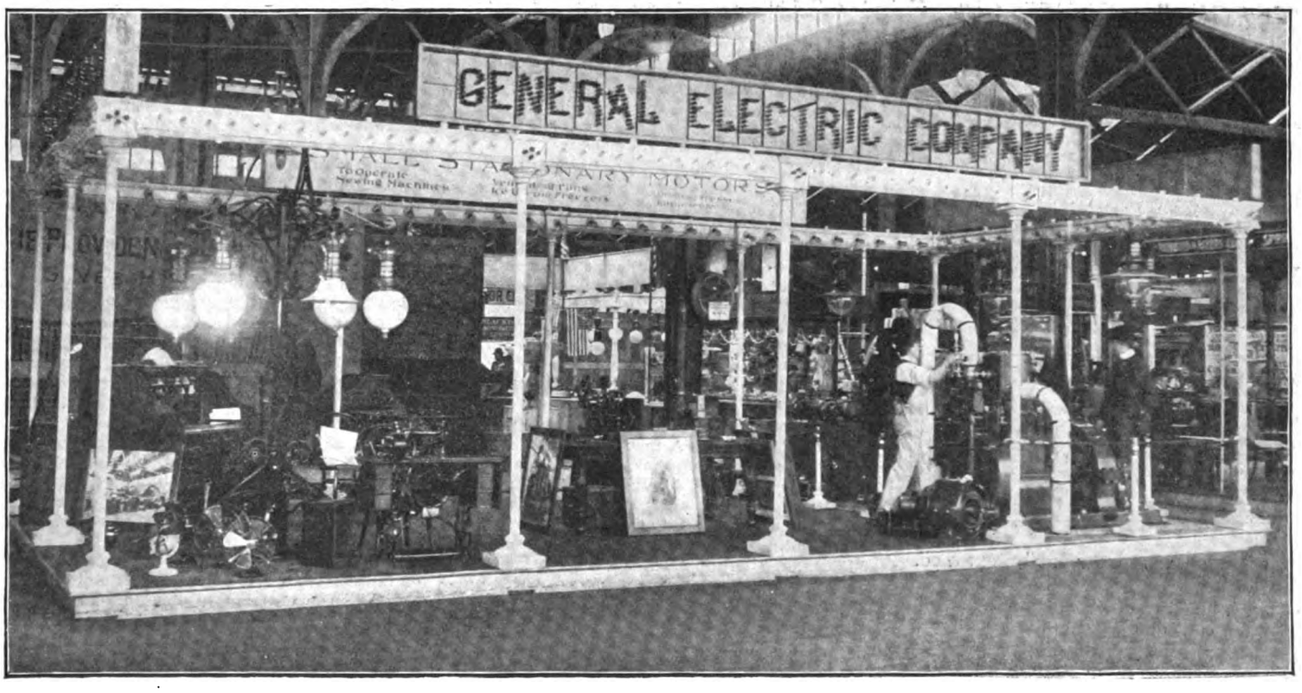
The power plant of the exposition is in a special building adjacent to the tracks of the Pennsylvania Railroad. The boiler room contains three batteries of two boilers each, the boilers being rated at about 300 h. p. each. One battery was built by the Stirling Company, Chicago, one by the Heine Safety Boiler Company, St. Louis, and the third by Robert Wetherill & Co., Chester, Pa. The engine room contains one Armington & Sims engine,

Digitized by Google

THE EXHIBITS OF THE CUTTER COMPANY AND OF THE GENERAL ELECTRIC AUTOMOBILE COMPANY.

driving two 125-volt 600-ampere G. E. dynamos. Another unit consists of an engine built by the Ames Iron Works, Oswego, New York, direct coupled to a Siemens & Halske 75-kw. generator of the outside armature type. Still a third engine is one built by the Harrisburg Foundry & Machine Works, which is designed for direct coupling, but at the time of the writer's visit was not fitted with a generator.

The steam piping from the boiler room to the engine room is neatly arranged, the pipes being fitted with Ludlow double-gate valves and covered throughout with H. W. Johns' asbestos coverings.



This power plant supplies two separate distributing systems throughout the main building, one of 110 volts and the other of 220 volts three-wire running incandescent and arc lights and motors. The switchboard of the plant was built by W. T. Pringle and, with the wiring, was installed by Keller, Pike & Co. The work was put in with great rapidity, the board, for example, being ordered on Sept. 4th and in service on Sept. 14th.

In addition the exposition gets alternating current at 5000 volts, two-phase 66 cycles from a station of the Pennsylvania Manufacturing, Light & Power Company, which power is transformed down in a pair of Wagner 250-kw. transformers to 2500 volts, at which pressure it is distributed throughout the grounds. The transformers are fitted with movable contacts by which the number of turns can be changed to alter the secondary pressure through a range of about 10 per cent. Quite a large number of Wagner single-phase motors are run throughout the exhibits from the alternating current mains.

The electric lighting is accomplished by means of some 5000 incandescent lights and some 450 arc lamps. Of these incandescents between 3000 and 3500 are used for illuminating the exterior of the main building, an idea of the effect obtained being given by the illustration on the previous page.

The lights grouped on the tops of the numerous flag poles are of 50 and 32 c. p., while those used to outline the windows are only of 10 c. p. All the incandescent lamps used by the exposition were made by the Fostoria Incandescent Lamp Company. The lighting of the grounds outside the building is largely accomplished by means of incandescent mantle burners of various types, worked with petroleum products.

The chief engineer of the exposition is Mr. John Birkinbine, President of the Franklin Institute, the electrical work being under the immediate charge of Mr. C. O. C. Billberg.

## THE EXHIBITS.

Of the exhibits in electrical and the allied lines of steam and street railway engineering there are so many that but brief mention of each can be made in these columns.

The General Electric Company has under the direction of its foreign department perhaps the most comprehensive collection of electrical apparatus in the exposition. The machines shown are so far as possible in actual service, being driven in part by power derived from a 15-kw. General E ectric marine set mounted and running in the booth, and in part by alternating current from the a.c. mains of the exposition described above. The new constant current alternating arcs of what are known as the Hartford system are in service in this booth to the number of four, supplied by a 3-kw. transformer designed to give 6.6 amperes to the lamps when run from a 2200-volt primary circuit. The transformer case is fitted with windows, through which the construction of the interior and the operation of the parts on the vice for recording wattmeters and an electric driving equipment for sewing machines. This consists simply of a small a.c. or d.c. constant speed motor belted to the sewing machine over an idle pulley. This pulley and a brake are attached to a pedal so that the speed of the machine can be adjusted mechanically. The direct current motor for this purpose is shunt wound and is fitted with an armature resistance which is automatically cut out by a centrifugal device on the motor armature.

The exhibit which comes next in interest to the average electrical engineer is that of The Cutter Company, Philadelphia. The space occupied by this company contains one large board covered with more than 50 breakers of the different types and sizes made by this company for all purposes. The largest circuit breaker of the collection is one of the new laminated wedge type described in the July issue of the American Electrician and rated at from 2000 to 5000 amperes. The variously operated releasing devices designed to respond to overloads, underloads, over-voltage, under-voltage, relay, etc., are to be with many breakers it frequently becomes desirable to temporarily increase the operating point of a large number of breakers to carry a heavy load for a short time or while

THE ARC LAMPS OF THE C. J. TOERRING COMPANY.

throwing in new generators, or otherwise disturbing the load in such a way as, so to speak, to electrically jar the circuit breakers.

THE EXHIBITS OF THE WAGNER ELECTRIC AND MANUFACTURING COMPANY AND OF THE S. MORGAN SMITH COMPANY.

magnetic repulsion principle can be seen. Of motors the booth contains the new C.E. type for direct currents and two samples of the single-phase induction motor, one of which is equipped with the new condenser starting

THE APPARATUS SHOWN BY QUEEN & CO.

device, while the other must be started by hand, but runs up to speed in either direction. Among other apparatus are the two-rate meter, the prepayment or coin-in-the-slot de- found in many standard types in this exhibit besides many combinations which in the present state of the art may be styled by the term "freak," although, as the needs of electric plants become more varied these freak combinations may become standard types. The underload breaker, for example, is made in a polarized form in the laminated wedge type, the polarization being obtained by adding a shunt coil around the one magnetic circuit. This modification makes the breaker operative only to reverse currents, the armature of the compound wound magnet only letting go when the series current reverses from its normal direction. Another interesting type is the double coil, triple-pole type for three-wire or polyphase systems, the two coils being respectively in the outer conductors of the three-wire system or two legs of a three-phase system, thereby protecting the lines against an overload on either side in the former case or an overload on any phase in the latter case. A new and ingenious departure in circuit-breaker construction is embodied in what is known as the internal-shunt type. This consists of a breaker with the ordinary latch and plunger, the series coil surrounding the latter being fitted over a high-wound shunt coil. This shunt coil can be connected up at times with a weak current in such a direction as to oppose the magnetism set up by the series coil so as to increase the load which the breaker will carry without opening. On street railway boards Instruments of this internal shunt type with their auxiliary coils all connected to one switch can at an instant's notice have their operating limit increased in this manner. The shunt coils can also be used in connection with a push button and a strong reversed current to throw the breaker on the relay principle.

The arc lamp exhibits are four in number. The Jandus Electric Company, Cleveland, Ohio, has in the exposition a sample of each of its various types of lamps. The C. J. Toerring Company, Philadelphia, has on view a number of its lamps which were recently described in these columns. The Helios Electric Company of Philadelphia makes a showing of its arc lamps and switchboard work, and the International Arc Lamp Company of New York also occupies a booth.

Of wire and cable manufacturers there are two representatives. The Standard Underground Cable Company of Pittsburg has a number of show cases containing samples of its products for various branches of electrical work. The John A. Roebling's Sons Company makes practically the same exhibit as that made at the Electrical Show in May of this year.

Of electric elevators the only exhibit is that of Morse, Williams & Co., Philadelphia, who installed the three main elevators in the exposition building and in addition occupy a booth where they show various samples of their apparatus.

Digitized by Google

Of instruments and electrophysical apparatus Messrs. Queen & Company, Philadelphia, make a showing of the Queen-Wirt measuring instruments and portable testing sets. An interesting instrument in the Queen-Wirt portable projection galvanometer for lantern use. This consists of an instrument with a needle projecting out horizontally over a lantern slide on which a vertical scale is mounted. By inserting the slide in the stereopticon the exact position of the needle on the scale can be projected on the screen.

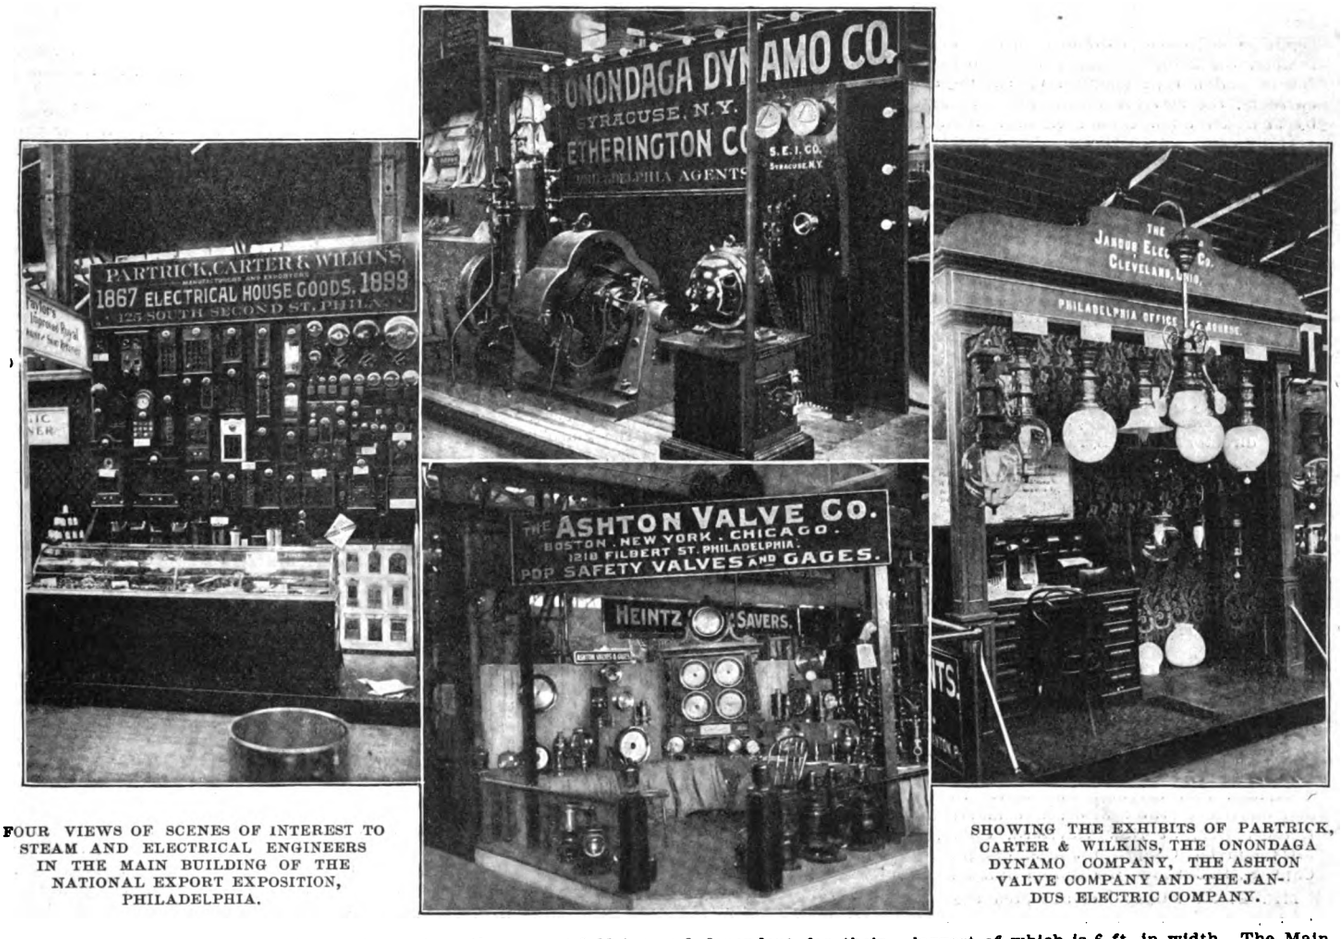
Of electric automobiles the General Electric Automobile Company, Philadelphia, makes the only exhibit, but one so complete that it partially makes up for the lack of others. The exhibit is contained in the building devoted to vehicles, its only competition in the automobile line being some carriages fitted with steam motors. An idea of the appearance of the exhibit is given in the illustration on page 543. The vehicles shown are one delivery wagon, one brougham and one runabout.

Of gas engines the most extensive exhibit is that of The Otto Gas Engine Works, Philadelphia. The exhibit contains as its main features one 60-h.p. engine driving part of the shafting of the main building and another 60-h.p. belted to a dynamo. These engines have some recently designed features, one of which is a new self-starting arrangement which consists of a hand pump for pumping air and gas into a chamber connected with the cylinder head, where it may be exploded when the piston is at the proper point of the cycle, giving the engine an initial impulse sufficient to turn it over and allow it to bring itself up to speed. In addition to these engines there are others driving respectively a Wagner 200-ampere dynamo and a Diehl 22½-kw. generator, besides hoisting and pumping engines.

Of general power transmitting machinery The Geo. V. Cresson Company, Philadelphia, makes an extensive exhibit containing one piece of apparatus of particular electrical interest. This consists of a magnetic separator designed for the concentration of magnetic ores. In addition there are Pelton water motors, samples of shafting, pulleys, etc.

Of valves and general steam fittings there are many. The Eynon-Evans Manufacturing Company, Philadelphia, has a booth filled with Eynon-Korting compound injectors, steam traps, blowers and blast nozzles, compressors and exhausters and steam jets for removing gases or liquids all on the injector or ejector principle. The Ludlow Valve Manufacturing Company has an exhibit space filled with substantial looking supplies turned out from its works at Troy, New York. Among them are indicating valves, hydraulic gates, float valves, relief foot valves, etc. The Ashton Valve Company, Boston, Mass. makes the exhibit of its "pop" safety valves, water relief valves, gages, etc., which is familiar to the attendants at previous expositions. The William S. Haines Company, Philadelphia, shows its pressure regulators, thermometers, thermo-regulators, safety, valves, steam traps, etc., generally known by the name of Heinz and dependent for their operation upon the expansion and contraction of a flattened tube.

Of pipe coverings for heat insulating purposes the only exhibit outside of the material used on the piping system of the plant is made by Keasbey & Mattison, Ambler, Pa. The exhibit consists of magnesia coverings in straight tubes and various special forms such as T's, Y's and elbows, asbestos wick packing and Ambler asbestos air cell covering.



Of turbines the only exhibit is that of the S. Morgan Smith Company, York, Pa. This company's booth contains samples of McCormick and New Success turbine wheels in both the vertical and horizontal types, the latter being in a closed flume. The vertical shaft wheels illustrate both the cylinder gate and the adjustable guide-chute methods of governing.

Of general electrical supplies and house goods an extensive exhibit is that of Partrick, Carter & Wilkins of Philadelphia. The booth of this company, which is shown in one of the accompanying illustrations, contains a complete line of annunciators, bells, etc., as well as more special apparatus, such as tank alarms, burglar alarms, with automatic clock cut-offs, servant's calls, etc.

Of motors, transformers, switchboards, ventilating sets, etc., the Wagner Electric Manufacturing Company, St. Louis, Mo., makes an extensive exhibit, a view of which appears on the preceding page. Besides this, Wagner single-phase motors are scattered around the buildings and one Wagner motor generator set consisting of a single-phase motor coupled to a d. c. dynamo is used in the vehicle building.

Among the manufacturers of belts three are prominently represented at the exposition. J. E. Rhoads & Sons of Philadelphia have in addition to their belting in use in the power plant a booth containing many samples, the largest of which is 6 ft. in width. The Main Belting Company, Philadelphia, shows a full line of Leviathan belts from the 90 in. 8-ply down. Chas. A. Schieren & Co., New York City, also make an interesting showing in addition to having considerable belting in use around the hall.

Of boilers the exhibits—besides those mentioned above as in use in the power plant—are two in number. One of these is the newly reorganized National Water Tube Boiler Company of New Brunswick, N. J., showing a model of its boiler. The other exhibit is made by the Harrison Safety Boiler Works, Germantown, Pa. This exhibit contains Cochrane separators and receiver separators, a large heater and purifier and a section of the Harrison Safety boiler.

## LEGAL NOTES.

THE STANLEY INSTRUMENT COMPANY vs. THE GENERAL ELECTRIC Company.—The Stanley Instrument Company of Great Barrington, Mass., has brought suit against the General Electric Company for infringement of a patent on alternating-current wattmeters. This patent is No. 423,210, issued March 11, 1890, to O. T. Blathy, the Stanley Company claiming that the patent is fundamental and covers broadly induction wattmeters. Both of the two claims of the patent, however, specify independent and non-intersecting magnetic circuits excited respectively by the shunt and series coils, an arrangement that is not used in many meters.

POLYPHASE MOTOR CASE.—An opinion was handed down Sept. 27th, 1899, by Judge McPherson of the Circuit Court of the Eastern District of Pennsylvania, in the case between the Tesla Electric Company (absorbed by the Westinghouse Electric & Manufacturing Company), complainant, and Scott & Janney, et al., defendants, alleging infringement of patents No. 511,915 and 555,190, granted to Nikola Tesla. These patents claim "split-phase" devices for alternating-current motors, the Scott & Janney motor being of the induction type supplied by single-phase currents, the starting torque being obtained by short-circuited coils each surrounding a part of each pole. The opinion upheld the complainant.

## PERSONALS.

MR. ENOS M. BARTON, president of the Western Electric Company, was married in London, England, on Friday, October 6th, to Miss Mary Rust, daughter of Major Henry A. Rust, Chancellor of the University of Chicago.

MR. IRA A. McCORMACK, formerly superintendent of the Brooklyn Rapid Transit Company, has resigned from this position to become the vice-president and managing director of the Syracuse Rapid Transit Company.

MR. H. C. FARNSWORTH, who for a number of years travelled throughout the New England States, selling electrical machinery, is now representing the Sprague Electric Company in that territory, having offices in the Exchange Building, Boston.

Mr. R. McALLISTER LLOYD has been elected president of the Electric Vehicle Company in place of Mr. Isaac L. Rice, who has retired from this position as well as the presidency of the Electric Storage Battery Company to attend to other pressing business.

LIEUT. FRANK J. SPRAGUE, the well-known president of the Sprague Electric Company, and inventor in electric railway and electric elevator fields, was married on October 11th, at New Hartford, Conn., to Miss Harriet Chapman Jones, daughter of Capt. H. R. Jones of the United States Army.

MR. D. M. BLISS has accepted the offer of a position with the New England Motor Company, Lowell, Mass., as Superintendent and Electrical Engineer of the company's new factory. Mr. Bliss spent several years with the Holtzer-Cabot Company of Brookline, Mass., and more recently has been connected with the B. F. Sturtevant Company, Boston, Mass.

MR. W. J. JOHNSTON, formerly publisher of the "Electrical World," who started from this country in August for a trip around the world, has been reported in Japanese papers as being in Japan during the latter part of September. From Japan Mr. Johnston goes to the Philippines and then completes a circle of the globe by visits to Java, India, Egypt, Turkey, Greece, Spain, etc. After attending the Paris Exposition Mr. Johnston expects to return to New York during June or July, 1900.

## TRADE PUBLICATIONS.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., have published their pamphlet entitled "A Book of Success" describing the work and equipment of the schools, in a special cover designed as a souvenir of the National Export Exposition. The schools are also circulating a leaflet giving the commissions which will be allowed to students in case they aid in securing the enrollment of others.

THE STEWART ELECTRICAL COMPANY, Cincinnati, O., has adopted the bulletin method of advising its patrons and possible patrons of its ability to meet their wants. Recent bulletins call attention to the Stewart Company's willingness to supply the needs of users of electrical machinery from the want of a new commutator brush to the purchase, sale or exchange of a complete plant.

THE SPRAGUE ELECTRIC COMPANY, New York City, has published a handsomely illustrated catalogue of the Lundell generators. In addition to the well-known single-field coil type the company is now building a larger machine of what is known as the split-pole type embodying a new principle designed by Mr. Robert Lundell for forcing the increased field strength with increased load into the proper horn of the pole to give correct commutation.

THE LYNN INCANDESCENT LAMP COMPANY, Lynn, Mass., shows the nature of its work to its correspondents by three full-sized illustrations of lamps printed on the back of its letter heads. One of these shows a 55-volt lamp after renewal by the Lynn Company with a filament of the plain horse-shoe type. Another shows a 110-volt lamp after renewal with the type of filament which the company uses for this purpose, viz., the coiled filament. The third shows the lamp which the Lynn company makes for 100 to 125 volt circuits containing a filament of the oval-anchored type, the filament being fastened to the glass stem instead of to a metal support.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., is trying to impress steam engineers about the country with the value of Dixon Ticonderoga flake granite for the lubrication of cylinders and valves. With the increasing use at the present day of high steam pressures, and especially of superheated steam, cylinder lubrication with oil is far from satisfactory. A mineral oil lacks body and animal oils char with the high temperatures of modern steam practice and form a gummy mass on cylinders and pistons. A finely ground flake graphite gives a body which with mineral oils is not affected by any degree of heat, and fills up the microscopic inequalities of the bearing surfaces, making them almost ideal in smoothness.

THE MURPHY IRON WORKS, Detroit, Mich., is circulating a leaflet signed by Mr. O. D. Cotton, criticising a pamphlet previously circulated by the Hawley Down Draft Furnace Company containing a report of the comparative tests of the Hawley down draft furnace and the Murphy automatic stoker carried out at the Oliver rod mill of the American Steel & Wire Company in Pittsburgh. Boiler tests involve so many factors that it is possible in a report of them to misrepresent the conditions and thus falsify the conclusions, and Mr. Cotton's contention in the criticism above referred to is that the engineers making out this report were influenced in favor of the Hawley Company and that the report was on this account an unfair one to the Murphy stoker.

THE SHERWOOD MANUFACTURING COMPANY, Buffalo, N. Y., lists in its catalogue of engine and boiler supplies a large number of improved appliances for engine lubrication and boiler cleaning. Among the former are automatic cylinder lubricators, oil pumps and oil cups of various types, and among the latter are flue scrapers, flue blowers and the "Niagara" tube cleaner. This instrument is intended for removing the scale from the interior of water-tube boilers of the straight tube type and consists of a small turbine mounted on ball bearings and attached to rotating cutters. By inserting this into the water-tube and driving a jet of steam or a powerful stream of water at high pressure through it the turbine rotates the cutters at a high speed and disintegrates the scale, which is washed away with the jet. The "Niagara" tube cleaner is claimed to be the original machine of this type, and is the specialty of the Sherwood Manufacturing Company. About 1000 are already in use in this country. The confidence of the makers in its satisfactory action is so complete that they send it on approval. The Sherwood Manufacturing Company has depots in New York, Boston, New Orleans, St. Louis, Chicago and San Francisco.

THE CLING-SURFACE MANUFACTURING COMPANY, Buffalo, N. Y., in a reprint of Prof. R. C. Carpenter's report of tests of Cling-Surface noted in the American Electrician of May, 1899, gives further data of interest abstracted from a letter from Prof. Carpenter written Oct. 5th, 1899, and reading as follows:

"Later tests of the use of Cling-Surface on belting substantiate in every particular the statements made in my report of April 17th. They also indicate higher efficiency of transmission and less loss of power in the case of belts treated with Cling-Surface than in the case of belts not so treated, when working under the conditions prevailing at the time of the earlier test. This is due to the fact that the slipping of a belt causes considerable loss of power, the power so lost passing off in heat. The use of Cling-Surface reduces the slipping and consequently reduces the loss of power occasioned by the use of belts that slip.

"During the past six months I have had occasion to observe the practical use of Cling-Surface in a number of instances. In all such cases Cling-Surface has improved the belts by softening them, and as far as I can determine in the limited time (seven months) tends to preserve the leather of which they are constructed."

## BUSINESS NEWS.

THE CREFELD ELECTRICAL WORKS, Saylesville, R. I., have been bought by the American Electrical Works, and the plant has been removed to a substantial new three-story brick building 130 ft. by 60 ft., adjoining the American Electrical Works' factories at Phillipsdale, R. I.

E. W. BLISS & COMPANY, Brooklyn, announce that they have recently moved their Western Office to 22-24-26 South Canal St., Chicago, Ill., where they will carry a full line of their standard machines and where Mr. W. D. Smith, who is in charge, will be pleased to communicate with any one in that section who is interested.

THE BALL ENGINE COMPANY, Erie, Pa., has sold to the Machinery & Electrical Department of the United States Commission to the Paris Exposition a 350-h. p. tandem compound engine, arranged for direct connection to a Bullock generator, to be used as a working exhibit in the machinery annex at Vincennes.

TROTTER'S MONA MANUFACTURING COMPANY, LIMITED, manufacturers of Trotter's commutator compound, has removed its offices from 65 W. Broadway, to more commodious quarters at 320 Broadway, New York, where Prof. Trotter will be pleased to receive his friends, and all interested in the commutator compound.

Digitized by Google

THE NATIONAL CONDUIT & CABLE COMPANY suffered on October 13th from a fire which did about $100,000 worth of damage at the company's works in Hastings, N. Y.

ROSSITER, MACGOVERN & CO., New York City, have purchased the entire factory, tools, machinery and equipment of the old Excelsior Electric Company in Brooklyn, N. Y. This will increase greatly the facilities and resources of Rossiter, MacGovern & Co. in their work of repairing and renewing second-hand electrical machinery.

THE AULTMAN-TAYLOR COMPANY, Mansfield, Ohio, has closed a contract with the New York Gas, Electric Light, Heat & Power Company, the Whitney syndicate controlling the Edison and other lighting companies of Manhattan Island, for 56 boilers, aggregating 3900 h.p., to be installed in the new Riverside generating station in New York City.

THE NEW YORK TRADE SCHOOL began on October 27th a series of 12 lectures for journeymen electrical workers, to be carried through the winter. These lectures are conducted by Mr. Arthur Hamerschlag, and consist of simple talks concerning the materials and the proper method of doing the work that members of the audience customarily engage in.

THE TUCKER MANUFACTURING COMPANY, York, Pa., reports that its business has increased to such an extent as to compel the placing of new machinery throughout the entire factory. The company is now prepared, owing to these increased facilities, to fill orders promptly. The company is arranging to increase its capital stock from $5,000 to $25,000.

THE WESTINGHOUSE MACHINE COMPANY proposes to build a steel foundry and steel forging mill at East Pittsburgh that will cost $1,250,000, and have a capacity of 80 tons of steel castings and forgings per day. The new plant will be erected immediately to the west of the present shops, and will consist of two steel frame buildings about 400 ft. long and 150 ft. wide.

MR. CHAS. J. BOGUE, New York City, has recently sold two focusing electric arc lamps designed for running in series with each other on direct current for use in the photo-lithographic work of the Department of the Interior of the United States Government. The United States Engineer's Office has also bought from the same maker one 14-in. pilot-house projector.

THE NEW ERA IRON WORKS COMPANY, Dayton, O., manufacturer of the "New Era" gas and gasoline engines, has recently purchased a new plant, which it is now remodeling and equipping with all the latest improved machinery. The demand for the "New Era" engines has been such as to warrant this action, which by January first will double the capacity of the company's works.

MANUFACTURERS of arc and incandescent lamps, porcelain fittings and general wiring materials for out and indoor work are invited to send catalogues, price lists, etc., to Mr. E. R. Dodge, Mechanical Electrician at the Civil Engineer's Office of the United States Navy Yard, Portsmouth, N. H. This yard will have a considerable amount of construction work in the near future and bids on material will be asked.

GATES & RANDOLPH, Chicago, report a constantly increasing business and that they have sold thirty odd complete electric plants during one month. Realizing the coming extensive use of electric motor carriages, they have also taken the agency of the Indiana Bicycle Company of Indianapolis, manufacturers of the "Waverly" automobile in all styles. A number of these carriages were on exhibition at the street railway convention.

THE UNION BOILER TUBE CLEANER COMPANY, Pittsburg, Pa., has recently finished what is claimed to be the largest contract ever awarded for cleaning boilers, being for twenty-two water tube boilers, containing an aggregate of ten miles of 4-in. tubes. The company has just shipped eight machines to England and Scotland. The first machine exported was shipped just one year previously. One of those recently shipped was a repeat of the first order.

THE CUTLER-HAMMER MANUFACTURING COMPANY, formerly of Chicago, on account of the great increase of its business, has been compelled to seek new quarters. The new location is in Milwaukee, Wis., where the company will occupy a three-story brick building specially erected for its use. The building has been equipped with the latest and most approved machinery and will enable the company to turn out a much larger product than it could handle at the old location. The Cutler-Hammer Company has also an office at 136 Liberty Street, New York City.

THE NEW ENGLAND MOTOR COMPANY, Lowell, Mass., reports a steadily increasing demand for its products. That its new four and six-pole slow-speed motors and generators meet the needs of motor users is evidenced by the number of orders obtained for them. The factory has been working overtime for the past six weeks, turning out the bipolar type in medium and smaller sizes. The company has recently equipped a new building with the most modern tools so that it is now in a position to furnish machines from ½ to 150-kw. capacity, and can make prompt shipments of the sizes most in demand.

THE PIERCE-CROUCH ENGINE COMPANY, manufacturers of gas and gasolene engines, with works located at New Brighton, Pa., reports having sold during the month of September for use in electric lighting plants in the Pittsburg district alone five 35-h.p. and one 25-h.p. engines. Besides this there were sold many engines for other purposes, one sale being the last two of eight engines furnished one company. When these two are installed the entire plant of this company will be run by gas engines. The Pierce-Crouch Engine Company is adding new machinery to its plant, which will soon enable its output to be doubled.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, O., reports sales for the month of September involving sixty-one machines ranging in size from three to one hundred and fifty kilowatts. Among the more important were fifteen engine-type generators for United States army transports and ten 50-h.p. motors to operate at 200 r.p.m., for Messrs. Dick, Kerr & Co., of London, England. A new bulletin No. .0435, just issued by the company, describes type "N" motors. This is the first bulletin of the standard 6 in. x 9 in. size which has been issued. Those interested in electrical literature will appreciate this reduction in size, as it is more readily filed than the larger pamphlets.

THE WOODS MOTOR VEHICLE COMPANY is the name of the new corporation which has taken over the building of electric automobiles under the designs of Mr. C. E. Woods, as formerly carried on by the Fischer Equipment Company of Chicago. The success of automobiles in general and the Woods vehicle in particular is such that the company has been incorporated with a capital stock of $10,000,000, and with a directorate containing such well-known men in the financial world as Messrs. John W. Mackay, August Belmont, Dr. W. Seward Webb, Sir William Van Horne, etc. The company starts out with complete designs for thirty different styles of vehicles, embracing a general line from the light buggy to victorias, broughams and cabs.

THE MANHATTAN GENERAL CONSTRUCTION COMPANY, Newark, N. J., manufacturer of the "Manhattan" arc lamp, is meeting with marked success in the introduction of the Manhattan series alternating current enclosed arc system described in the last issue of this paper. Among some of the contracts which have been closed the company mentions contracts for 850 lamps and 9 regulators for the San Gabriel Electric Company, Los Angeles, Cal.; 1 regulator and 25 lamps for the People's Gas & Electric Co., Peoria, Ill.; 1 regulator and 35 lamps for the Electric Light Co. of Hot Springs, Ark.; 3 regulators and 117 lamps for the Middlesex & Monmouth Electric Co. of Mattewan, South Amboy and Keyport, N. J. The company is operating its factory at Newark night and day in an endeavor to catch up with the orders at present on its books.

THE WARREN MANUFACTURING COMPANY, Chicago, Ill., offers belt users a simple solution of the problem of slipping belts. Every engineer realizes that a highly polished iron pully is about as unsuitable a device for transmitting power to belts as could be arranged since it requires a very high belt tension to obtain the necessary resistance to slippage. This belt tension increases journal friction, wears out the belt and is generally troublesome. Leather and canvas coverings are often used, but they are troublesome through the necessity of frequent renewals. The Warren Manufacturing Company offers a liquid pulley cover which can be applied with a brush, dries in a couple of hours, and is then ready for use. This pulley cover is not injured by oil or grease. It is designed to cure the troubles incident upon too short a distance between belt centers and to allow dynamos and motors to be placed nearer together in cases where it is desirable but otherwise impossible to do so.

THE MURPHY IRON WORKS, Detroit, Mich., has obtained a second order for Murphy automatic smokeless furnaces at The Standard Plate Glass Company's works at Butler, Pa., the first order having been installed last spring under guarantee of superior results in every respect over the front feed stokers then in use. The American District Steam Company, Lockport, N. Y., is also installing Murphy automatic smokeless furnaces in place of the mechanical stokers of another make installed there last year. Murphy automatic smokeless furnaces are also to be placed in connection with the eight 400-h. p. B. & W. boilers in the new central power plant of Swift & Company at the Union Stock Yards, Chicago. The company also has been given the contract for equipping the fourteen 250-h. p. boilers for the Columbia Chemical Company's large new works at Barberton, O. The Wagner Sleeping Car Company also has contracted with the Murphy Iron Works for Murphy automatic smokeless furnaces for the boilers in its works at Buffalo, N. Y.

THE MANHATTAN BUILDING, St. Paul, Minn., has been sold to Mr. Charles Lockhart, one of the Standard Oil magnates of Pittsburg, Pa. This sale includes the Manhattan Light, Heat & Power Company, which was operated to supply the building and neighboring structures as a sort of block central station. The price paid for the building and the lighting and heating plant was $500,000. The new company has contracted for additional machinery for the heating and lighting department, having purchased a 250-h.p. water tube boiler from the Stirling Company, Chicago, and an engine from the American Engine Company, Bound Brook, N. J., which is direct connected to a 75-kw. generator made by the Triumph Electric Co., Cincinnati, O. The company is also installing a large marble switchboard, having the very latest appliances, and contemplates extensive improvements and extensions in its underground system. Mr. A. Wilford Zahm, formerly Superintendent for the Manhattan Light, Heat and Power Company, has been retained as Manager for both the Manhattan Building and the Manhattan Light, Heat & Power Company.

## STREET RAILWAY CONVENTION NOTES.

A. L. IDE & SONS, Springfield, Ill., were represented by their genial Chicago agent, Enos Bookwalter.

OF THE ARNOLD ELECTRIC POWER STATION COMPANY, Chicago, Mr. B. J. Arnold and Mr. George A. Damon were at the convention.

MR. FRED H. ALDEN, President of the Illinois Insulated Wire Company, Sycamore, Ill., had his usual pleasant word for all his acquaintances.

A. C. BECKEN, Chicago, exhibited a case of Paillard non-magnetic watches which are claimed to be absolutely uninfluenced by magnetic or electric action.

THE BALL ENGINE COMPANY, Erie, Pa., while not making an exhibit, had its interests carefully attended to by its western representative, Mr. W. A. Kreider.

THE HEINE SAFETY BOILER COMPANY, St. Louis, was present in the person of its Chicago representative, James H. Harris, who has represented this firm in Chicago for nearly twelve years.

Mr. E. J. BAGNALL of the Adams-Bagnall Company, Cleveland, O., managed to spend a few hours at the convention, where he renewed many old acquaintances. Mr. Pomeroy, western representative of this company, was also in evidence.

THE WARREN MANUFACTURING COMPANY, 65 S. Canal St., Chicago, was represented by Mr. E. H. Warren, Pres., and Mr. Alfred Warren. They showed a line of samples of their liquid pulley covering and a vast number of testimonial letters.

THE WESTERN ELECTRICAL SUPPLY COMPANY, St. Louis, which has rapidly built up a large business in the Southwest in the handling of street railway supplies, was represented by the manager of its street railway department, Mr. Chas. Scudder, Jr.

THE CLING-SURFACE MANUFACTURING COMPANY, Buffalo, N. Y.—Mr. F. C. Willis did the honors of the convention for this company. It is questionable whether any company distributed larger quantities of printed matter than did this company during the sessions of the convention.

THE GREEN ENGINEERING COMPANY, Chicago, was represented by P. Albert Poppenhusen. This company has recently secured several of the largest orders ever placed for traveling grates. The company represents the Edgemoor Iron Co., Goubert Mfg. Co., Broomell, Schmidt & Co.

THE MILLER-KNOBLOCK COMPANY, South Bend, Ind., was represented by its manager, Mr. A. W. Morrell. The exhibit showed a full line of assembled commutators for all standard street railway motors, the workmanship on which attracted general attention. Constantly increasing business has made it necessary for the company to double its capacity.

THE EUREKA ELECTRIC TELEPHONE MFG. CO. of Chicago made one of the interesting exhibits, because it was nearly the only one in its line. This company manufactures a line of special telephones adapted for street railway work and found many interested inquirers among street railway delegates. Both Mr. Kusel and Mr. Stein were in attendance.

THE SPEER CARBON COMPANY, St. Marys, Pa., had able representation in the person of Mr. Jonn S. Speer, General Manager of the company, assisted by Mr. Andrew Call, Sec. and Treas. The product of the company was kept prominently to the front and the representatives were most generous indeed with souvenirs, giving out a handsome coin and bill case, pocketbook and cigar case.

THE SWARTS METAL REFINING COMPANY, Chicago, has a name well known to street railway people throughout the continent, through its business in the handling of worn-out trolley wire, scrap windings, brass castings, etc., etc. The company also furnishes a superior metal for motor bearings, which is coming into general use on many roads. The company was represented by its president, S. Swarts.

THE CENTRAL UNION BRASS COMPANY, St. Louis, was represented by its manager, T. C. White. This company is bringing out an extensive line of overhead material and making a special effort to meet the most exacting street railway demands. Mr. White reports that the factory is very busy and that the new material is meeting with much favor from street railway companies.

THE WESTERN ELECTRIC CO.—The exhibit of this company was made at its shops on the West Side, but a handsome souvenir was given out at the convention by the representatives present—a handsome match-box in white enamel and silver, showing the W. E. fan on one side and a "Petite" arc lamp on the other. Mr. A. L. Tucker visited the convention, while Mr. J. C. Cannon, Mr. Thos. Grier, Mr. Philip de F. Rust and Mr. Frank Swan were constant in their attendance.

THE CENTRAL ELECTRIC COMPANY, Chicago, has a very handsome booth decorated in yellow and black and with a number of steel trolley poles spanning the doorway. There was exhibited a display board made up of overhead material, car fixtures, etc., elegantly polished. These were mostly of the well known Wood type, manufactured by the Central Union Brass Company. A brass cannon, a yoke of brass oxen, and a brass street car attracted no small attention. The company's souvenir was a neat brass paper cutter.

THE STAR BRASS WORKS, Kalamazoo, Mich., had a neat booth in charge of Walter C. McKinlock. This company's trolley wheels, which have been on the market not quite two years, are running on thousands of cars. Some of their points of superiority were as follows: It will run in sleet longer than any other; is self-oiling and therefore saves bushings; will run smoother and last longer; is a better conductor and is not complicated; will not injure the overhead equipment and is made in the standard sizes, 4 inch and 6 inch, and will fit any standard harp.

K. McLENNAN & COMPANY, Chicago, sole manufacturers of Gale's commutator compound, were represented at their exhibit by Mr. W. J. Isaacs, the manager of the company. One of the features of their exhibit was a large bulletin board on which were attached several hundred extracts from testimonials, and at the side of the board two original testimonials were displayed. Judging from the number of samples which they gave out at their booth their compound is valued by the users of dynamos and motors. A neat souvenir was distributed in the shape of a "Mauser" cartridge knife.

THE LESCHEN, MACOMBER, WHYTE COMPANY, Chicago, was represented by F. B. Macomber, George S. Whyte and E. E. Robirds. The exhibit consisted of galvanized steel strand, galvanized curtain cord, galvanized telephone wire, rubber insulated wires and cables, weatherproof feeder wire, magnet wire, "Century" tape, "Beacon" bearing metal, overhead line material, and the "Standard" headlight. A neat paper cutter was distributed as a souvenir. While the principal business of the Leschen, Macomber, Whyte Co. is wire rope, its trade in the street railway field is rapidly increasing and is now reaching large proportions.

THE SIEGRIST LUBRICATOR COMPANY, St. Louis, had its booth enlivened by one of the best "coon" orchestras in town, whose good music constantly attracted and entertained a crowd. The company's booth was a handsome one, decorated in purple. There were exhibited automatic oil cups and automatic sight feed lubricators; a double automatic lubricator, having the advantage of two passages for the feeding oil, which removes in a large measure the danger of stoppage on account of an obstruction in the oil passages; also the company's standard automatic oiling table. The company's man-

# A COMMUTATOR NECESSITY.

**For Sale by all Supply Houses.**

**Upon receipt of this coupon we will send FREE, sample stick.**

Name.....

ager, J. N. Edelin, was present with a constant supply of good cheer for his friends.

EUGENE MUNSELL & CO. AND THE MICA INSULATOR COMPANY, Chicago, made a combined exhibit at the street railway convention, occupying a space of 200 square feet near the entrance. This exhibit consisted of mica in its natural state and in its various forms for electrical insulation, also stamped mica segments and washers, both India and Amber. Very large specimens of mica were shown, of interest to all electrical engineers and street railway managers. The exhibit of the mica insulator Co. consisted largely of "Micanite" rings, segments, tubes, troughs, cloth, paper, etc., etc. The exhibit was in charge of Mr. Charles E. Coleman, who has charge of the western business of the two companies.

THE CREAGHEAD ENGINEERING COMPANY, Cincinnati, made its usual large exhibit of flexible brackets, overhead line material, iron and wood pole fittings, rail bonds, etc. One particularly attractive feature of this exhibit was an extra heavy double bracket for center-pole construction which was recently supplied for the rebuilding of the overhead work on the New Orleans & Carrollton Railway, at New Orleans, La. A number of large photographs showing the company's material in use on roads in different parts of the world completed this particularly attractive exhibit, which was in charge of the superintendent, Mr. G. R. Scrugham. A steel pocket rule was given as a souvenir.

THE WESTERN ELECTRIC COMPANY was represented at the street railway convention by Messrs. J. C. Cannon, Philip Rust and F. L. Swan. They had headquarters in booth 30, where they entertained friends of the company and distributed printed matter and souvenirs to the visitors. Mr. A. L. Tucker of the Western Electric Company, was one of a committee on publicity for the convention. The souvenir distributed by the Western Electric Company at the convention was a matchbox having on one side an illustration of a Petite arc lamp, on the other an illustration of a 16-inch fan motor, and on both edges of the box—"Western Electric Company, Chicago—New York." The box is finished in silver and white celluloid.

THE GARTON-DANIELS ELECTRIC COMPANY, Keokuk, Iowa, was represented by J. V. E. Titus. The booth contained a panel mounted with Garton station-type arresters of different finishes and connected with the 500-volt circuit. By the aid of a static machine, the operation of the arresters was shown in a very satisfactory manner. They interrupt a short circuit so quickly that an ammeter shows little or no deflection. On a table was displayed a line of pole, station and car arresters, as well as samples of 500 and 800-ampere kicking coils, of which this company makes a specialty. This company also showed two samples of the automotoneer, an invention of Mr. George W. Knox, of the Chicago City Railway Company. This device prevents too rapid starting of electric cars and attracted lots of attention.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, left its interests at the convention in charge of Messrs. Sam Mayer and Dudley Johnson, Chicago representatives, and Messrs. A. L. Harris, E. A. St. John and William Allen. The souvenirs of this company were large Uncle Sam pencils—also a trick pencil which, when once placed in the button hole, could not be detached without a deal of study, as well as plumbago medals made of the same graphite as that used in Dixon's pencils. The representatives of the company were kept busy booking orders for Dixon's graphited wood grease for gears of electric railway cars, of which they explained the merits in that it prevents noisy gears, keeps gears and bearings constantly lubricated, prevents all drippings from gear cases and lasts longer and is more economical than other lubricants.

THE GENERAL ELECTRIC COMPANY'S exhibit consisted largely of motors, containing, as it did, two G. E.-55 motors mounted on a truck complete as they will be used on the Northwestern Elevated in Chicago, two G. E.-1000 motors equipped with B-13 controller and electric brakes mounted on a St. Louis Car Company's truck, one G. E.-65 of 250-h. p. capacity built expressly for the Paris & Orleans Railway in France, and samples of the G. E.-52 and 57. There was also a line of standard switchboard panels, an air compressor, a large line of instruments, overhead material, motor repair material and apparatus for third-rail work. The delegates who attended the Convention in the exhibit of the General Electric Company were as follows: S. D. Greene, S. Trawick, Geo. Rosenthal, E. D. Mullin, T. P. Bailey, R. D. Beech, F. W. Willcox, F. E. Case, F. H. Strieby, A. H. Armstrong, W. F. Hayes, B. E. Sunny, F. Barbour, W. J. Ferris, E. D. Priest, J. J. Mahoney, F. M. Kimball, R. A. Swain, Geo. J. Cadwell, J. W. Johnson, W. B. Potter, F. N. Boyer, J. G. Barry, J. W. Buell, J. H Livsey, H. R. Bishop, Jr., Geo. Breed, R. E Moore, W. O. Carey, F. N. Boyer and Ward S. Arnold.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY made the most extensive exhibit in point of magnitude in the convention hall, its largest pieces of apparatus being a 500-kw. engine-type railway generator complete and a 200-kw. rotary converter with starting motor. Of railway motors assembled the company showed two pairs mounted in operating order on trucks, as well as three different styles assembled

THE
CROSS OIL FILTER

Do you throw away your oil after using it? If so you had better look up your oil bills and see how much money you are wasting. Oil is not injured by use. A little of it is wasted, the rest simply gets dirty. The Cross Oil Filter will take out the dirt and make it just as good as new.

and several armatures complete and one under construction with commutator partially connected to show the internal arrangement. Among these motors were the new types No. 68 and No. 69, which are the latest built by the company, the particular improvement embodied in them being the increased current-carrying capacity of the field windings sufficient to equalize the heating between the armature and fields. A decided departure in the same motors is the use of poles bolted to the yoke instead of cast in as has been previous practice. The exhibit also contained one complete railway switchboard having three generator, one load and six feeder panels. The representatives of the Westinghouse Company attending the Convention were as follows: Messrs. Wm. Bauder, J. M. Duncan, C. S. Cook, F. McCoy, J. H. Reid, C. E. Skinner, N. W. Storer, F. S. Smith, W. M. Probasco, of Pittsburg; Messrs. W. S. Rugg, Irvin Dryer, C. W. Regester, Frederick Nelson; C. G. Burton, W. R. Pinkard, L. M. Harvey, T. A. Hall, T. P. Gaylord, Ivor Hennings, of Chicago; C. H. Bragg of Philadelphia, R. S. Brown of Boston, H. C. Marsh of Cincinnati, C. S. Powell of Cleveland, C. F. Medbury of Detroit, T. Julian McGill of Minneapolis, J. R. Gorden and E. Woodruf of Atlanta, Ga.; W. W. Grant of Ottawa, Ont., and A. Hatet of the Westinghouse Electric Company of France.

THE AMERICAN STEEL & WIRE COMPANY, Chicago, made a composite exhibit of all the different products of the company applicable in any way to street-railway or electric traction interests, and the diversity of these products was in many ways a surprise to those not familiar with the extent of the manufactures of this company. High above the booth swung a mammoth "Figure 8" rail bond, which was illuminated with more than a hundred incandescent bulbs and at night was one of the most brilliant features of the entire exhibit. The words "Crown Bonds" were brought out with numerous electric lights. Crown bonds, indeed, in innumerable shapes and sizes—straight and twisted to every known curve and angle formed the "piece de resistance" of the American Steel & Wire Company's exhibits. These bonds, however, were supplements on every side of the exhibit with devices calculated to interest every department of street-railway maintenance and construction; trolley wires, round and odd shaped, feeder wires and cables, steel-armored cables, lead-encased cables, submarine cables, magnet wires, every form of insulated wire, wire ropes, rheostat cables, car-truck springs, etc. These, again, were reinforced by a full representation of guy wires and span wires, both plain and twisted, also with huge pyramids of "high grade W. & M." double galvanized telephone and telegraph wires in "Extra BB," "BB," and steel grades. Another feature was an exhibit of woven-wire right-of-way fence which now is an important feature in the right-of-way program of the traction companies which are going "cross lots" among the inter-urban highways, finding it necessary in many cases to have the right-of-way securely as well as economically fenced in. A panel of the company's celebrated "American" style of fencing was shown erected on the posts with stretcher attached and in operation. The space allotted to the American Steel & Wire Company was completely filled with objects of interest to those concerned in the construction or operation of electric traction lines and was a center of interest during all the crowded periods of the exposition. Souvenirs in the form of solid leather memorandum and pocket books were judiciously distributed. Mr. E. J. Pietzcker was in charge of the exhibit for the electrical department, and Mr. George P. Rider was in charge of the fence exhibit.

AMONG OTHER VISITORS TO THE CONVENTION not exhibiting but interested observers from the central station or other electrical fields were: Mr. George S. Searing, western representative of the Hart & Hegeman Mfg. Co., Hartford, Conn.; Mr. W. G. Amos, Chicago agent of the Murphy Iron Works, Detroit, Mich.; Mr. J. A. Jones, of Kohler Bros., Chicago; Mr. J. B. Castle, of K. McLennan Co., who slipped in to the Convention the last two days and made his friends glad by his presence; Mr. Louis T. Grant, Gen. Mgr. Hawaii Automobile Co., Ltd., Honolulu, H. I.; W. E. Pimlott, representing the Martin J. Insull Co. and the General Incandescent Arc Light Co., Chicago; Mr. J. W. Hayden of Sherman & Hayden, Chicago; Mr. George Cutter, of Cutter & Co., 180 Lake St., Chicago; Mr. Edward W. Grier, western manager of the Bryant Electric Co., Hartford, Conn.; W. W. Lowe, president of the Electric Appliance Co., Chicago; Mr. Henry Shafer, Gen. Mgr., and Mr. P. J. Hertz, of the Stromberg-Carlson Telephone Mfg. Co.; and Mr. J. E. Smith, Supt. of Motive Power for Armour & Company.

# RECENT ADDITIONS IN THE POWER HOUSE OF THE NIAGARA FALLS HYDRAULIC POWER AND MANUFACTURING COMPANY.

**A Description of Many Special Machines for the Generation of Direct Currents for Electro-Chemical Purposes from Hydraulic Power.**

The two great electric power generating systems of Niagara Falls have been developed along radically different lines. In one all the dynamos are of the same size and type, and the electric power generated by them is then transformed to the various kinds and voltages of current required by different consumers. In the other—the recent developments of which it is the purpose of this article to describe—the dynamos are of various types and sizes, each designed to deliver its output directly in the kind of current used in the consuming devices, thus doing away with intermediate transformations and conversions. Each plan has its advantages and disadvantages. The cost of generation of the power is undoubtedly lower when it is all generated in one form, but when it has to be converted into another form, such as direct current, the cost of this final form may become greater than if it were directly generated in the dynamos. For this reason the loads at Niagara Falls have naturally been divided between one or the other power house according to this basis. All loads which could use the more cheaply generated power in its original form, viz., 25-cycle alternating current, are carried by the one system, while all the loads of the other are direct currents or alternating currents of another frequency than 25 cycles.

At the beginning of the present year the power house of the Niagara Falls Hydraulic Power and Manufacturing Company contained one penstock loaded with wheels and generators and one comparatively new penstock 13 feet in diameter, the largest in the world in point of power output, carrying only one pair of wheels, although fitted with gates for five pairs, this pair of wheels driving only one generator, although fitted with couplings for two. The penstock comes vertically down the side of the cliff, bending around to the horizontal under the

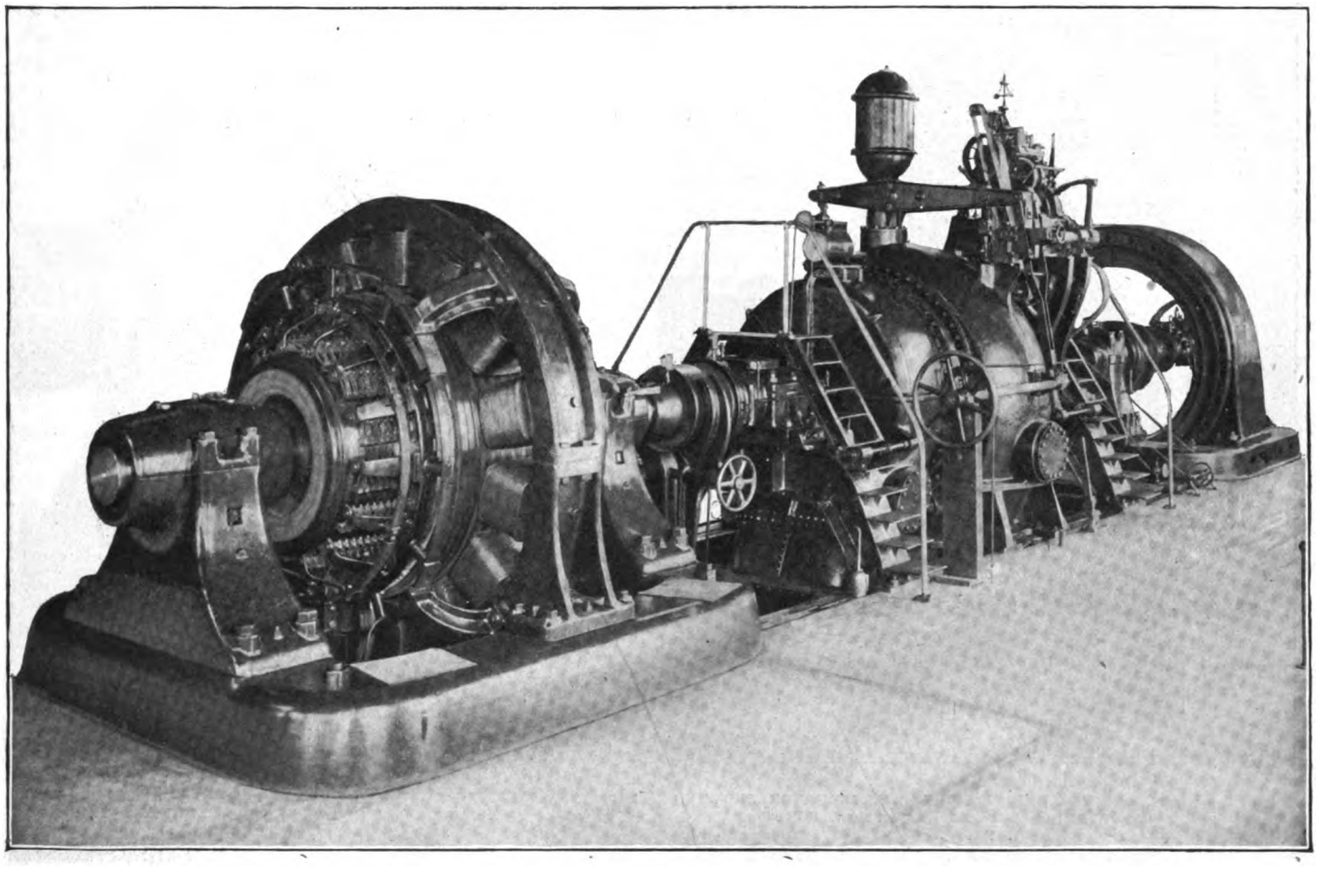

FIG. 1.—A 3000-H. P. PAIR OF TURBINES DRIVING A 5000-AMPERE DIRECT-CURRENT GENERATOR AND A REVOLVING-FIELD, 125-CYCLE SINGLE-PHASE ALTERNATOR.

Digitized by Google

power house floor and running straight out across the house toward the river. The inlets for wheels open vertically upward from the penstock, while below it is the tail race. The pair of wheels in service upon this penstock are of the Jonval type—that is, with axial flow through the runners, mounted on a horizontal shaft extended out to take a generator on each end. The wheels are 60 inches in diameter and rated at 3000 h. p. for the two when running at 250 r. p. m. under a head of 210 feet. The speed is controlled by a Reynolds governor.

Coupled to one end of the turbine shaft is a unique generator built by the General Electric Company, and designed for an unusually large current delivery. It is rated at 5000 amperes at only 175 volts, its current being used by the National Electrolytic Company for the production of chlorate of potash in a plant situated at the top of the bluff, nearly over the power house. This machine has two commutators, one at either end of the armature, the two sets of brushes being connected in parallel with each other. The division of the load between the two commutators is ingeniously accomplished by varying the load of one or the other set of brushes. The ratchets and handles for moving the brush-holding rings are shown in the illustration, Fig. 5. The saw-tooth clutch in the center is provided to move the two sets of brushes in unison. The division of the load is indicated by a Weston ammeter appearing in the same illustration, and connected up so that when the load is evenly balanced between the two commutators the needle of the ammeter reads zero, the scale of the instrument reading zero at the center. The shunt cords of this ammeter run to two terminals of a Y-shunt connected up as shown in the diagram, Fig. 2. As long as the current going through the shunt, A B, is the same as that through A C, the drop in both will be the same and there will be no difference of potential between the points, B and C. As soon, however, as one commutator takes more current than the other the equality of the drops in the two paths, A B and A C, is disturbed, giving a difference of potential between B and C which deflects the ammeter in one direction or the other, according to which commutator is taking the heavier load.

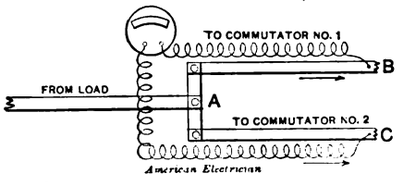

FIG. 2.—DIAGRAM OF Y-SHUNT CONNECTIONS.

During the past year there has been added to the plant an alternator which is coupled to the other end of the shaft of the same turbines which drive the double-commutator machine just described. This alternator is used for incandescent lighting and is owned and operated by the Buffalo and Niagara Falls Electric Light and Power Company. The machine is of interest from the fact that it was built by the Walker Company under a contract and designs drawn up shortly before the consolidation with the Westinghouse Company. It is the largest of the few alternating-current machines built by the Walker Company between the time this company decided to build alternators and the time of its absorption by the other company. The machine is also of interest from the fact that it is single-phase and high frequency, all other large alternators recently built being polyphase and with a frequency at the most of 60 to 66 cycles. The number of poles in this alternator is 60, giving at the normal speed of 250 r. p. m. a frequency of 15,000 alternations per minute, or 125 cycles per second. The field is the revolving member and to avoid crowding the large number of poles, the diameter of the air gap has been made large, some 9 or 10 feet, giving a peripheral velocity of approximately 7500 feet, or 1½ miles per minute.

The exciting current used in this machine is astonishingly large, being at no load 150 amperes, at nearly the same number of volts, amounting to 20 kilowatts, or about twice as much as is used, for example, in the famous 5000-h. p. Ni-

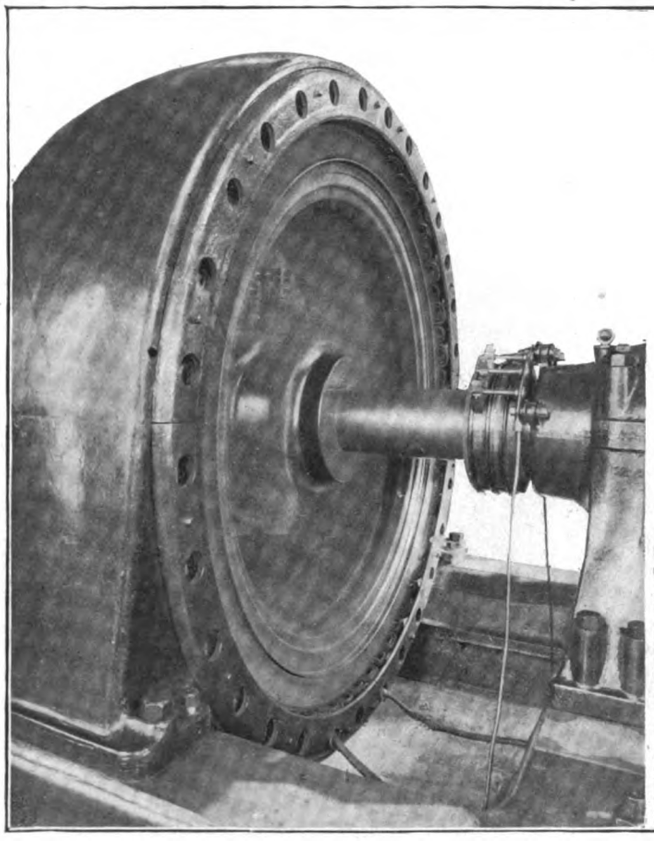

FIG. 3.—A VIEW OF THE HIGH FREQUENCY ALTERNATOR, SHOWING THE WINDING AND THE CLEARANCE FOR REPAIRS.

Digitized by Google

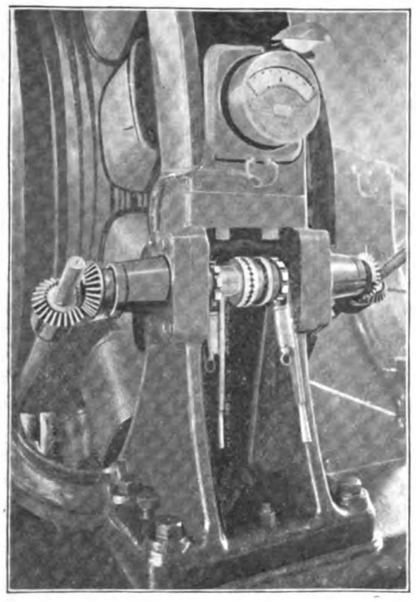

FIG 5.—THE BRUSH-ROCKING MECHANISM OF THE DOUBLE-COMMUTATOR MACHINE.

agara machines. This extremely large exciting current is due in part to the large number of small poles and in part to the high frequency, which requires a very stiff field to obtain a respectable regulation.

The winding of the stationary armature is distributed in four slots per pole, spread over 60 per cent. of the polar pitch, every fourth armature tooth being much wider than the others. The winding consists of one path from terminal to terminal, all the turns being in series with each other, the coils being distributed on the spiral or pan-cake fashion, as indicated in Fig. 3. As the same cut shows, there is a large clearance between the armature and the journal at the collector ring end. This is given to allow the stationary armature to be moved along the base until it clears the rotating field.

The machine is excited by a small four-pole Walker machine belted to it, the only peculiarity of this exciter being its rated pressure, which is 185 volts. By adopting this pressure, the alternator may conveniently be excited from the large electrolytic generator driven by the same wheel, in case the exciter fails.

The alternator was built for 700 kw., but tests upon it show that its best efficiency is given at about 900 kw., and that it will stand this load continuously without overheating. The Walker Company evidently wanted to be on the safe side in building a new machine and did not stint material and run the risk of rejection of the machine after test.

The switchboard panel of the generator is an unusual aggregation of apparatus from various makers, in spite of which it presents a very creditable appearance, as Fig. 7 shows. At the top of the panel are two Wagner instruments of the oil flotation type, for indicating the a. c. voltage and amperage. Below are a Weston round-type ammeter for the field and a Westinghouse integrating wattmeter to give a record of the kw. hours. The main field rheostat is Cutler-Hammer, the exciter rheostat is iron clad, and a Stanley transformer is used for pilot lights. A special and unusually handsome I. T. E. circuit breaker is the central figure on the panel. As may be seen in the illustration of the board, the tripping coil of this breaker is back of the panel, the front of the instrument consisting of four carbon breaks in series with each other at the top, shunted by a U-shaped knife below them. The breaker is single pole.

There has also been installed during the past year in the power house a 200-kw. 135-volt shunt-wound generator, made by the General Electric Company, the current from which is used by the Alloy Smelting Company in a secret electro-smelting process for the production of chromium. This machine is belted to a turbine on the old penstock, which turbine also drives a railway generator and a 500-volt machine on a motor load.

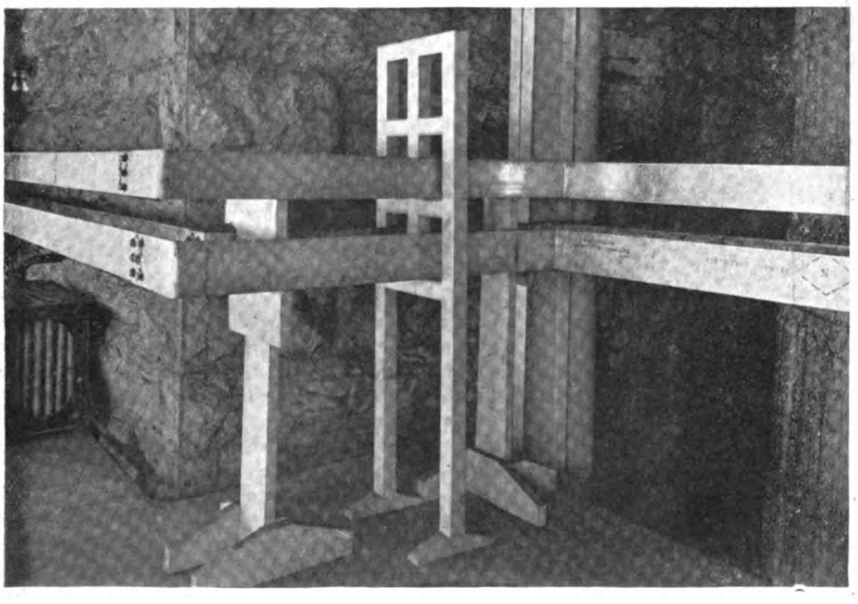

FIG. 6.—SOME ALUMINUM FEEDERS RUNNING TO ELECTRO-CHEMICAL ESTABLISHMENTS.

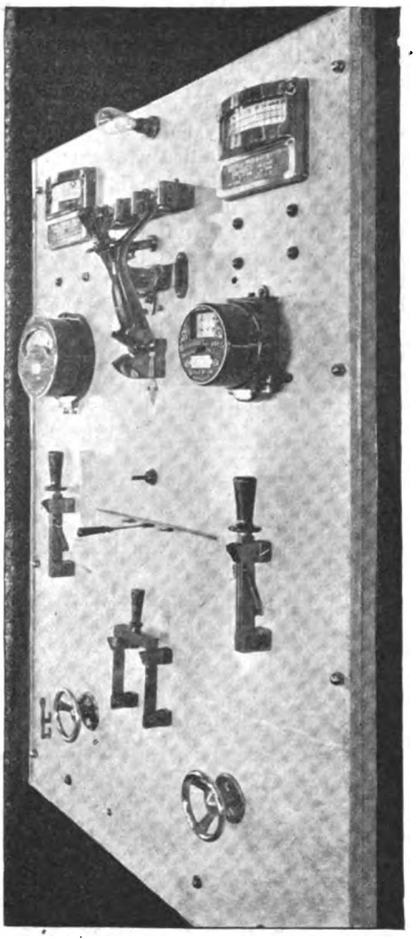

FIG. 7.—THE SWITCHBOARD OF THE ALTERNATOR.

There has also just been completed a new equipment of generating machinery for the Pittsburgh Reduction Co. to meet the increased demand for aluminum for use in place of copper as electrical conductors. This equipment consists of two pairs of turbines, each pair coupled to two Westinghouse generators. The turbines were built by R. D. Wood & Company of Philadelphia, and resemble closely that shown in Fig. 1. The new ones are, however, somewhat smaller, being rated at only 2300 h. p. per pair, that just referred to being of 3000-h. p. capacity. The new wheels embody some changes and improvements. Like the older ones, they are of the Jonval type, with improvements of Mr. Emile Geyelin, but in place of register gates the new ones have cylinder gates, which intercept the water before it reaches the distributors. While this modification would impair the efficiency at part gate, the machines of the Pittsburgh Reduction Company, as a rule, run steadily day and night under full load, besides which efficiency at part gate is no object in this plant. The cylinder gates cut off the water before it enters the distributors or guide chutes, and the whole area of passages through the runners remains open at all times. Thus on part gate the effective head upon the runner is reduced and the output of the wheel falls

Digitized by Google

off much more rapidly than does the flow of water. On this account the necessary motion of the gate for a given range of load is greatly reduced and the governing is correspondingly easy. These wheels will be governed by hand, no automatic governors being installed with them.

Since the water flows radially through the gates and axially through the runners it makes a quarter turn in the distributors on its way from the gates to the runners. The distributors are properly shrouded to deflect the course of the water in this way.

The cylinder gates of the new wheels are moved in and out toward or away from each other by cranks on vertical shafts, which are turned by a screw and nut mechanism, to be mounted on top of the unfinished wheels shown in Fig. 8.

The new wheels have also an improved form of thrust block. In the older 3000-h. p. unit the thrust blocks are of Babbitt metal mounted between the two bearings that come between the turbine and each generator. The adjustment of the shaft axially is made by means of bolts and nuts on rotating collars. Hence the machine must be shut down once every few months for this adjustment. With Jonval type wheels any axial displacement will cause the runners to strike the distributors. Whenever the thrust bearings wear the play must be taken up. This adjustment is likely to necessitate the shutting down of the machine at any time. The thrust blocks of the new machines are within the wheel case and are made of lignum vitae and lubricated by the water like the step commonly used between the two turbines of a pair. They are adjustable while the machine is running.

The wheels drive the generators through couplings of a special design, such that they can be uncoupled in a few moments' time. This coupling consists of a disc carrying a key which runs diametrically across the shaft. The key lies in two keyways, one in each half of the coupling. The disc and one end of the key may be seen in Fig. 4. The driving is all done through the key, so that the only bolts that are needed are two small ones to prevent the disc from slipping out of place. These can be removed in a very short time when it is desired to uncouple.

The reader may remember that the old machines of the Pittsburgh Reduction Company had couplings between the wheels and generators that were flexible in the sense that they contained springs through which the power was transmitted, these springs yielding with increase of load. The new machines have solid couplings, this flexibility being found unnecessary, especially with such a steady load as the aluminum process gives. The flexible couplings have also been removed from the old sets and solid couplings substituted, as the former appeared to cause heating and burning of the lignum-vitae steps between the turbines.

The new generators driven by these wheels are rated at 750 kw. each, being designed for the delivery of 2500 amperes each at 300 volts. They differ but little from the original machines of the same make installed some years ago for the same service. The only visible improvements made in these machines during the last few years are the support of the brush-rocking ring from the field yoke instead of from the outboard bearing, and the use of a protecting plate over the end connections at the back of the armature, as shown in Fig. 4.

In addition to the machinery just installed, and described above, there are under order two other pairs of wheels rated at 3000 h. p. per pair, which will be placed on the last two outlets of the big penstock. These wheels will be of a still

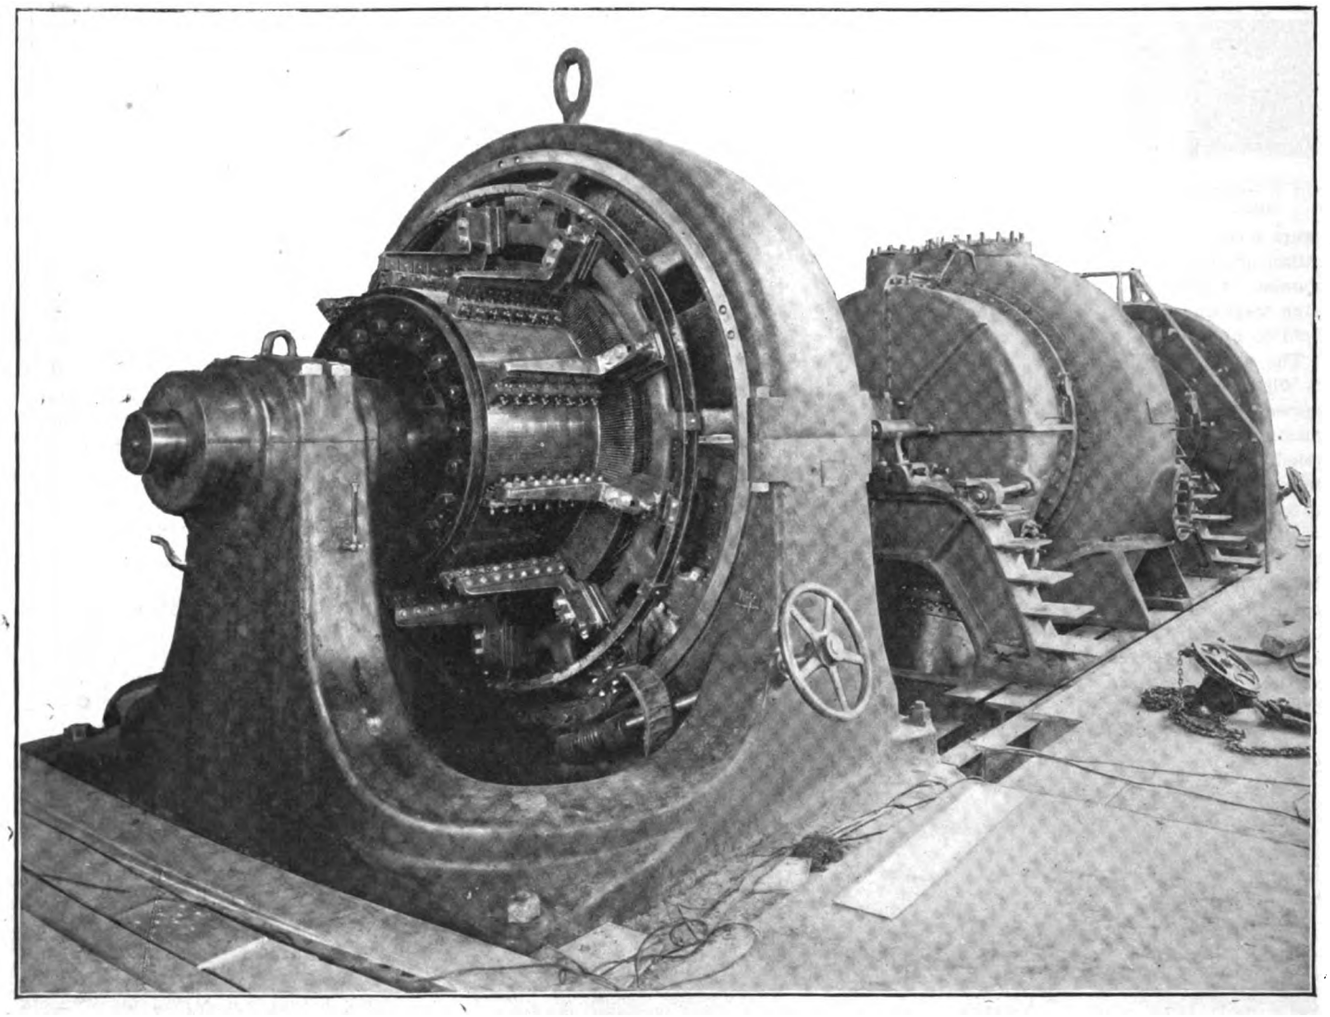

FIG. 8.—ONE OF THE NEW PAIRS OF TURBINES AND 300-VOLT GENERATORS OF THE PITTSBURGH REDUCTION COMPANY.

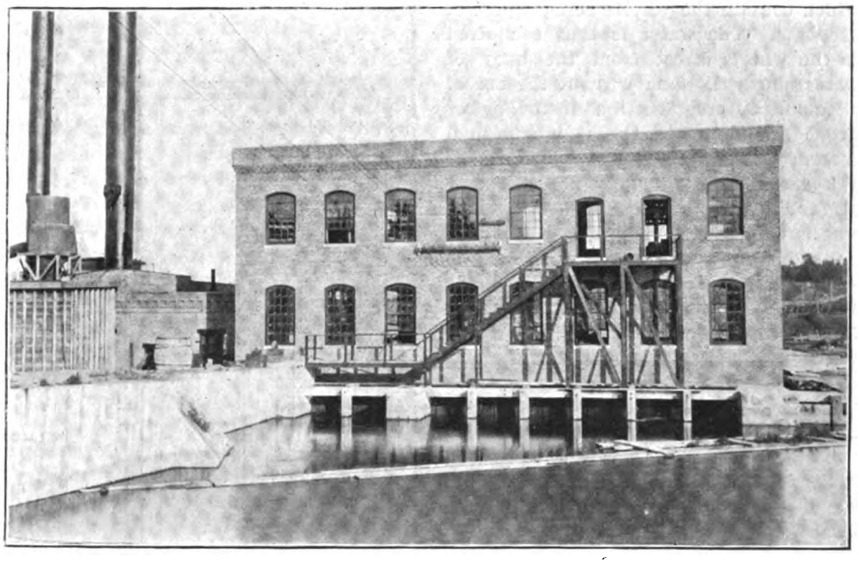
Digitized by Google

different type from any now in use in this power house, being designed on the more common inward radial flow principle. They are being built by the Wm. Cramp & Sons Ship & Engine Building Company, Philadelphia, commonly known as Cramp's shipyard.

These new turbines will drive another 5000-ampere machine for the National Electrolytic Company, a duplicate of the double-commutator machine described above, and three 1000-kw. 325-volt General Electric machines, which will deliver current to the Acker Process Company. This current will be used for the electrolytic production of alkalis from common salt, but the process will be unique in that the baths will not consist of salt in an aqueous solution, but of fused or molten salt maintained at the proper temperature by means of the $C^2R$ losses of the high current density within it.



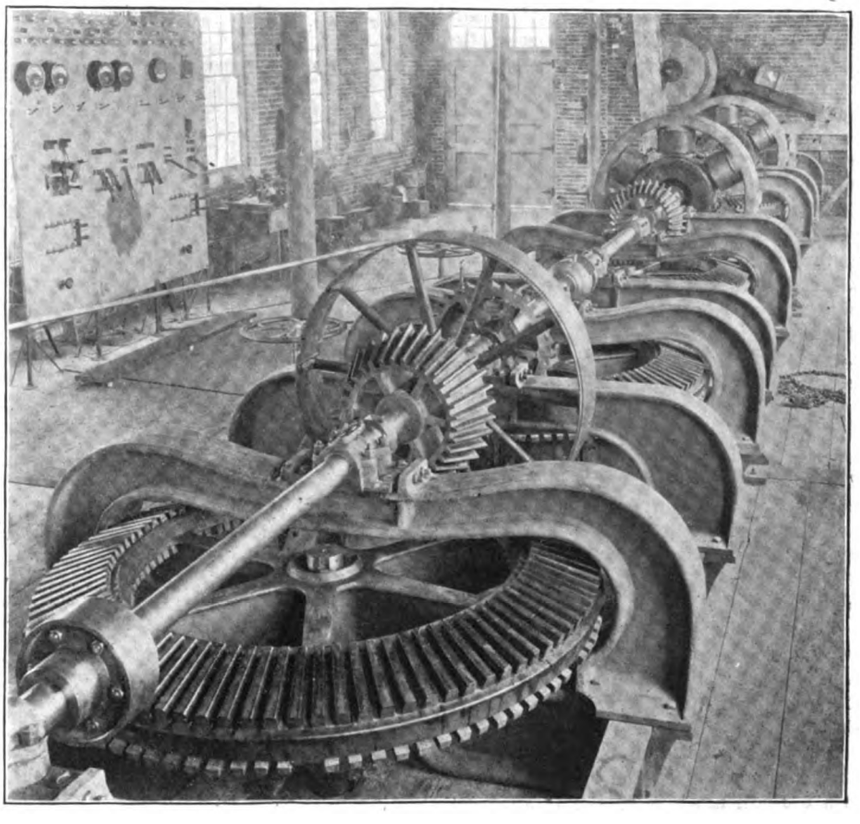
The power house now contains altogether the following equipment of machines:

| | Kilowatts |
|---|---|
| Six old 280-volt, 2000-ampere generators for Pittsburg Reduction Sompany..... | 3360 |
| Two 560-volt, 1000-ampere generators, one on railway and one on motor loads.... | 1120 |
| One railway booster..... | 75 |
| One 175-volt, 5000-ampere machine for the National Electrolytic Company..... | 875 |
| One 135-volt, 1480-ampere machine for the Alloy Smelting Company..... | 200 |
| Four new 300-volt, 2500-ampere machines for the Pittsburg Reduction Company. | 3000 |
| One 2200-volt, 410-ampere, single-phase alternator for the Buffalo & Niagara Falls Electric Light & Power Company ..... | 900 |
| One exciter ..... | 30 |
| Total present capacity of plant..... | 9560 |

To provide for further increase of business in future, work has already been started on a new penstock to the right of the present one, as looked at from across the river. This new penstock will be a duplicate of the last one, and hence capable of delivering 12,500 h. p. with a very moderate velocity.

The canal of the company, from the river, above the rapids, through the town to the penstocks running down the side of the cliff, has been enlarged during the past year, so that there is now a channel 14 feet deep and with a width of 40 feet. The company possesses the right to draw all the water it can through a channel of this depth and 100 feet wide. With the very moderate fall of 2 feet such a canal would pass sufficient water to generate, under the head obtainable, over 100,000 h. p., that is to supply eight or ten such penstocks as that recently built and that about to be put up. If present indications are correct, the construction of these penstocks will proceed in quick succession until all are in place and use. The water front for about a mile along the gorge is owned by this company, giving ample room for a very large equipment of penstocks and wheels. By increasing the fall in its canal slightly the company can, when future demands warrant it, generate many hundreds of thousands of horse power.

For the information given above thanks are due Mr. W. C. Johnson, the hydraulic engineer in charge of the whole work, to whom credit is also due for the solutions of many original problems, some of which are mentioned above.



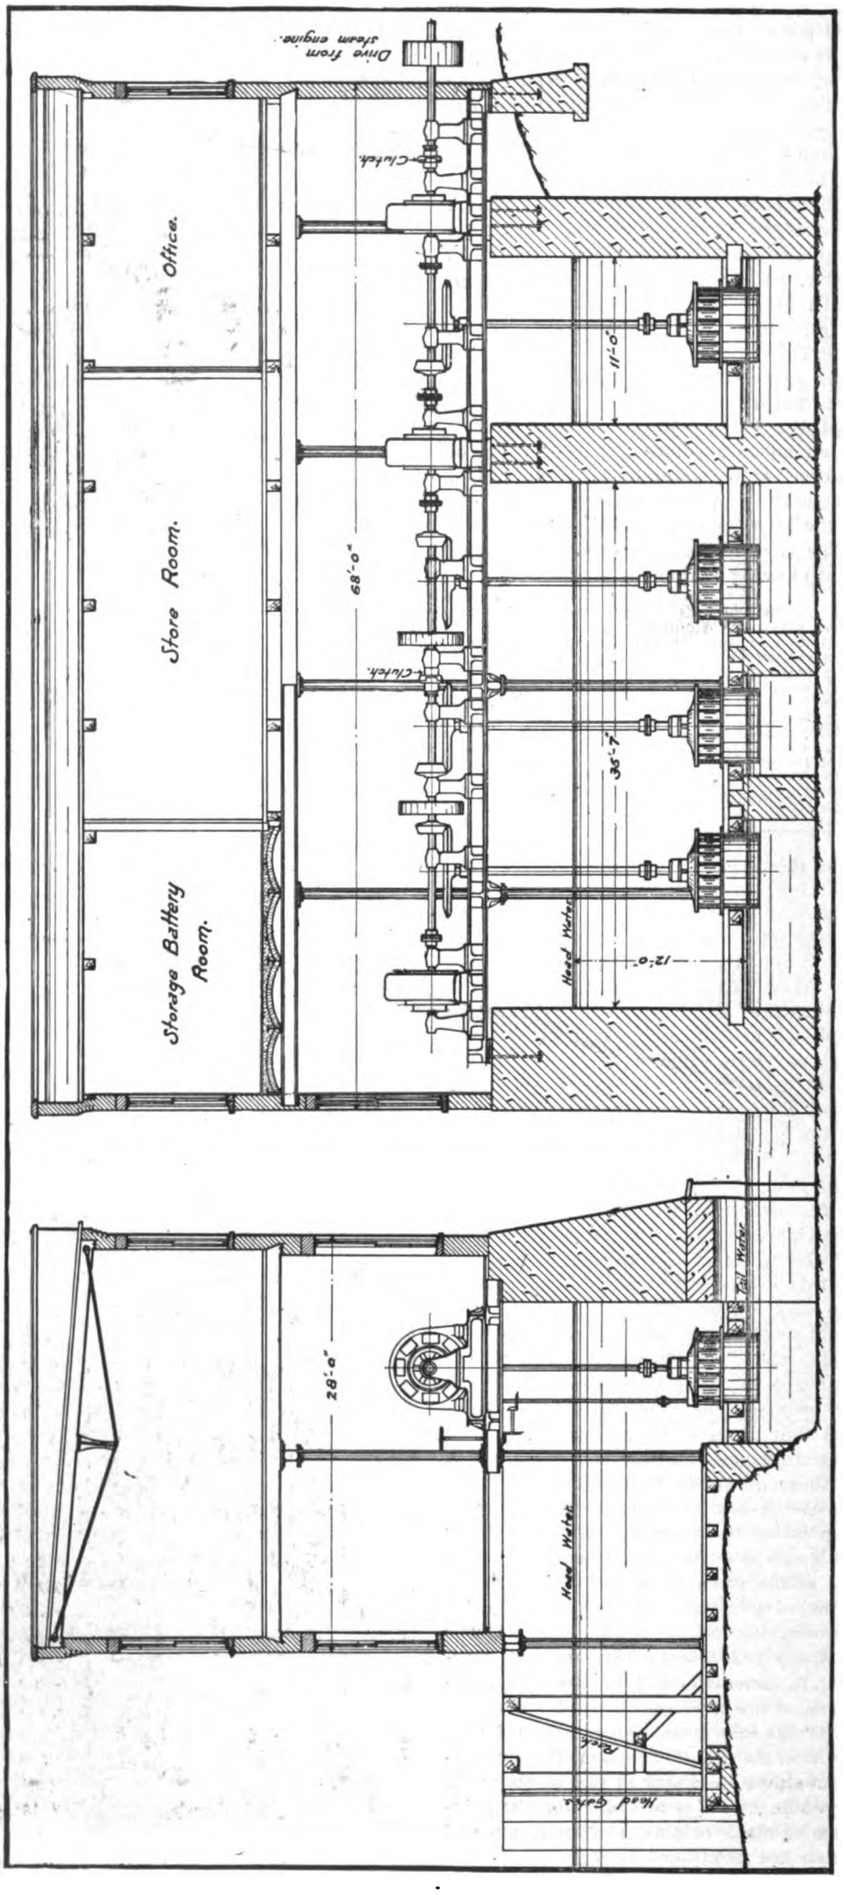
# The Power Plant of the Merrill Railway and Lighting Co.

BY F. E. WOODFORD.

To build a power and lighting station in a small city where it is expected that the number of consumers will be somewhat limited, it oftentimes becomes a problem to arrange the equipment to meet the variety of demands upon it, and still have it so simple and compact as to run on an economical basis. It is of course desirable to have the generating units as large as possible, and as few in number.

The new plant of the Merrill Railway and Lighting Company of Merrill, Wis., presents a unique arrangement of a combined hydraulic and steam power station with several turbines and generators on one shaft for both incandescent lights and electric railway service, delivering direct current only at one voltage. The power house, a view of which is shown above, is built on the river side, the flumes

THE INTERIOR OF THE MERRILL POWER HOUSE, SHOWING THE GEARS.



Digitized by Google

which contain the wheels being a part of the dam. The water is thus conducted to the wheels direct from the body of water above the dam without the use of a canal. A cross section of the power house is shown with a longitudinal section on this page. The bed of the Wisconsin River at this point is nearly all solid rock, consequently excavation was unnecessary except to a depth sufficient to allow a free discharge from the wheels. Upon this rock bed are built the walls of the flumes which also form the foundation for the building proper. These walls are of stone laid in cement, the outer ones being 6 feet and 7 feet thick, with the partition walls 4 feet thick. The building is of brick, two stories in height, the lower story consisting of one room 68 feet long and 28 feet wide, in which the generators and switchboard are placed. The upper story is divided into three rooms. The outer one toward the river end is provided with a concrete floor and contains the storage battery plant. The middle room is used as a store house, while the end away from the river has been fitted up for an office.

On the land side of the main building and not connected with it, except by a covering for the belt way, is the steam engine and boiler room, with its equipment, which is not shown in the section.

The wheels are 42-inch new American, of the upright type, and under the head of 12 feet they run at a speed of 102 r. p. m. Directly above the wheels, and resting on the stone walls, is an iron harness extending the entire length of the building. This harness forms the foundation of the three generators shown in the section, and also the cast-iron yokes which take the bearings of the shaft. As will be seen, the four wheels are geared to a horizontal shaft extending the entire length of the harness, and upon this shaft are mounted the armatures of the generators. The shaft extends through the end of the main building, at which place power is applied to it from the steam engine. There are two clutch couplings in this shaft, one at the end of the building, which cuts off the engine, and the other cutting off the outer generator and that part of the shaft driven by the two outer wheels. By this arrangement two wheels may be run, driving two generators, or the other two may be run driving one generator. Or, at a time of low water, two or all of the wheels may be run in connection with the engine. Three of the wheels are placed in one flume, while the fourth is separated from the rest by a partition wall, so that any repairs may be made without shutting down the entire plant. A view of the harness and gears is shown on page 551.

The generators are of the General Electric Company's manufacture, the two toward the land end of the plant being 100-kw. each, 250 volts, and running at a speed of 300 r. p. m. They are connected in series and feed into the storage battery in the room above. The other generator is a 500-volt machine at the same speed,

CROSS AND LONGITUDINAL SECTIONS OF THE MERRILL POWER PLANT, SHOWING THE ARRANGEMENT OF THE TURBINES, GEARING AND DYNAMOS.

Digitized by Google

and when run operates in parallel with the other two.

The storage battery plant consists of 240 cells of 500 ampere-hours capacity. With the exception of the series arc lamps, all power and lighting current is taken from the storage cells.

During the day the street railway and the shop motors compose the load, as a day lighting circuit is not run at the present time. The street railway is two miles long, and runs two, sometimes three, cars of eight tons each, which take an average of from 20 to 30 amperes. The other motors require about 40 amperes, so the load all day does not exceed an average of 70 amperes.

The lighting current is taken by five wires from the battery, and delivered by separate circuits to the different parts of the town. The heavy lighting load occurs between seven and ten o'clock at night, and this added to the street railway equals 200 to 240 amperes, the maximum number of lights being 1500.

The generators run all day with scarcely any adjusting, delivering the average amount of current required, the battery taking any excess and supplying any shortage. At night some adjusting of the water wheel gates is needed when the lights are thrown on, and from ten to twelve, when the lights are being turned off, the generators and wheels require a little attention.

The two arc machines are at the up-river side of the building, and do not show in the section. They are belted direct from the shaft on which the armatures of the other generators are mounted.

The storage battery is a perfect governor. The three direct-connected generators and two arc machines are run upon the same shaft, under a varying load, and while there is no balance wheel on the shaft, it is not necessary to govern the speed except by hand.

The steam engine in connection with the plant develops 250 h. p. at 90 r. p. m. Under the present conditions it is necessary to run the engine only at a time of extremely low water, or in case of some repairs being made to the flumes or wheels. In fact, it has not been in use at all as yet. But while the plant is built in excess of the present needs of the town, it is expected that the demands upon it will keep increasing until the engine will be needed as an auxiliary during heavy load.

The operation of the plant is extremely simple, requiring only one attendant at all times. It has been in operation for over a year, giving the best of satisfaction to both the owners of the plant and the consumers of its power.

# The Design and Construction of a Modern Central Lighting Station.*

BY H. H. HUMPHREY.

An ordinance, passed by the Municipal Assembly of the city of St. Louis, Mo., in the fall of 1896, threw open the doors to all applicants for underground conduit rights. Among the applicants were several newly organized companies, and one of them has since constructed its plant. The Imperial Electric Light, Heat and Power Company first turned current into its underground system one year ago, October 15, 1898, and has been in continuous and successful operation since that date. This paper is a discussion of the design and construction of this plant, which embodies many interesting features.

This plant was intended primarily to compete for business in the down-town or underground district of St. Louis. It was required, however, that the system adopted should be capable of being extended beyond this district, and, if necessary, of covering almost the entire city. The success of the three-wire direct-current low-tension underground system in this and other countries naturally influenced the engineers in its favor. On the other hand, the cost of copper for such a system, while not strictly prohibitive, is still so large as to demand most serious study.

The class of service to be supplied had great weight in the final decision regarding the system. This service consists largely of 500-volt direct-current motors, there being also some 220-volt motors of smaller size. Another important part of the service was to be arc lighting. The growing popularity of the inclosed arc lamp indicated that this field would be very profitable. The furnishing of incandescent light was by no means of secondary importance. In order to reduce the first cost of station equipment and underground work, both conduits and cables, it was deemed advisable that all three kinds of service should, if possible, be supplied from one generator, delivering its output through one underground duct and one service cable.

These considerations led to the adoption of a three-wire direct-current system of distribution, differing in important details, however, from the methods heretofore employed. 220-volt incandescent and 220-volt arc lamps were both to be used on the sides of the three-wire system, while 500-volt motors would be connected directly across the outside wires. The saving in copper over the usual 110-220-volt system, based upon the same percentage of drop, is three-fourths. Furthermore, the area which can be supplied from one central station at the same percentage of loss is increased sixteen times. If in the 110-220-volt system the limit with a certain drop be placed at one mile from the station in all directions, an area of 3.14 square miles can be covered. With the 220-440-volt system the distance reached from the station in all directions is four miles, covering an area of 50.24 square miles. By the proper use of boosters with storage batteries at the ends of feeders, such a system may be extended over a district within a radius of 10 miles from power plant.

The next question in point of importance was the location of the plant. It would be natural to assume that such a plant should preferably be located upon the river front in order to secure cheap water, and upon a railway switch to secure cheap fuel. In this case, however, no suitable property was available on the water front. Furthermore, fuel coming from Southern Illinois district can be delivered by wagon from East St. Louis almost as cheaply as when bridge and

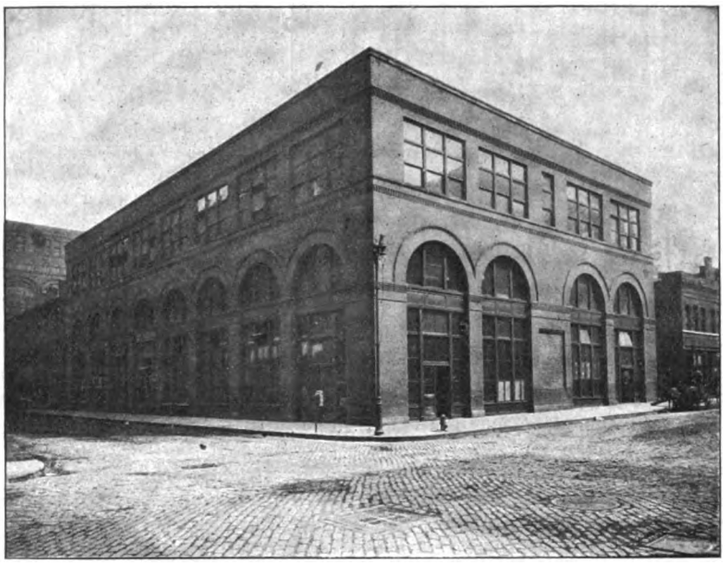


FIG. 1.—EXTERIOR VIEW OF IMPERIAL STATION.

*From a paper read before the Engineers' Club of St. Louis, Oct. 18, 1899. Slightly abstracted. Illustrations from Proceedings Association of Engineering Societies.

Digitized by Google

switching charges are paid on carload lots unloaded at the plant. Very few St. Louis power plants are located upon railway switches, and one large plant, which is so located is supplied with coal hauled in wagons from East St. Louis. Under these circumstances the plant should be placed as near the electrical center as possible. A suitable lot was found at the southeast corner of Tenth and St. Charles streets, and the plant was located there.

The designing of a plant which would ultimately utilize to the best advantage all the limited space available was next undertaken. Before entering upon the details of this work, however, one of the engineers spent some time on an extended trip through the East visiting the large power plants in New York City, Boston, Pittsburg, Philadelphia, Buffalo and Chicago, making a study of the most modern plants in these cities. After much study it was decided to locate the boilers, dynamos and engines all upon the street level, rather than place part of the apparatus below street level, as is frequently done. A study of many different designs led to the division of the plant longitudinally, east and west, into an engine room and a boiler room, each extending the full length of the property; this plan giving an ultimate capacity of 10,000 h.p.

Hypothetical load curves were next prepared, covering the service expected from this plant, including incandescent and arc lights and motor service. The three were then combined into one curve representing the entire anticipated output of the plant under the heaviest service of the winter months. A study of this curve indicated that the number of units in the plant should be at least five. This number fitted both the minimum load, which was about one-fifth of the maximum, and provided admirably for reserve. In case of accident during the peak of the load, the other four units could take the place of the disabled one by each carrying 25 per cent. above its rating. In case of the adoption of a storage battery sufficiently large to carry the reduced load during the latter part of the night, and assist the generators during the times of maximum load, it was deemed safe to reduce the number of units to three, the battery to be of the same capacity as each of the units.

In designing the steam plant it was necessary to determine beforehand what economical auxiliary apparatus, if any, should be installed in connection therewith, as all of these affect the capacity of the boiler plant. The rule adopted by the engineers in determining whether any species of economical apparatus was worth installing was that it should be able to earn, under a conservative estimate of the conditions of service, and taking into consideration the low price of fuel in this territory, 18 per cent annually upon its first cost.

Applying this rule to the consideration of compound versus simple engines resulted in favor of the compound engine. A further comparison between compound non-condensing and compound condensing engines showed the ultimate economy to be in favor of the condensing type. Economy in the use of water, which is obtained from the city's mains at considerable expense, necessitated the installation of a cooling tower in connection with the condensing plant. The application of the above rule to the question of fuel economizers showed that they would be a good investment.

It was decided to use water tube boilers, as this type gives large capacity in small space, is absolutely safe, quick steaming, economical in fuel and can be had in large units. With good draft they may be overworked 50 per cent., and under mechanical draft they may be operated for short periods at double their rating. Down draft furnaces, of the type which has proven so successful in St. Louis, were selected. They are capable of burning low grade coal, running high in moisture and clinker, and may be overworked far beyond the rating of the boilers. They are also simple, easily repaired and not likely to get out of order. The most important characteristic, however, is that they are smokeless, thus complying with the city ordinances. They improve the fuel economy, and add somewhat to the boiler's capacity.

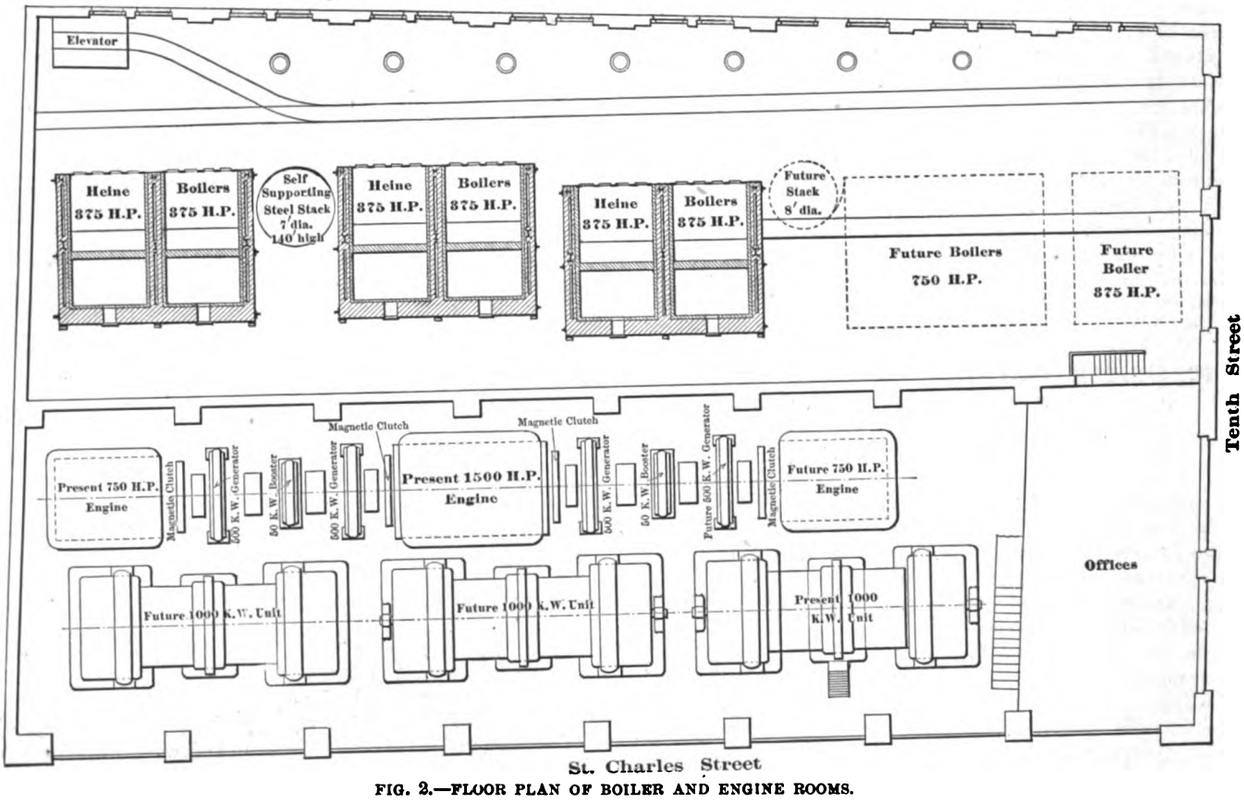

FIG. 2.—FLOOR PLAN OF BOILER AND ENGINE ROOMS.

It was decided at the outset to divide the total chimney capacity into two units, for the reason that the draft would be better at light loads, and one stack only needed to be built then, as but a part of the plant was to be installed to start with.

On account of the use of the 220-440-volt system of distribution and the many economical features of the steam plant, this station has attracted unusual attention. A detailed description of the apparatus used therein may therefore have more than passing interest.

BUILDINGS.

The building is of dark red brick, three stories high above the basement. The area under sidewalks on both streets is

Digitized by Google

excavated to the curb line, which forms the outer line of retaining wall. The second story is omitted everywhere except over the main office, thus giving a clear height in the engine and boiler rooms of 30 feet. The third story, which is 15 feet high, is devoted to store rooms, testing department, etc. All floors are of cinder concrete carried on corrugated iron arches sprung between I beams. The roof is of book tile with composition gravel covering. Engine and boiler rooms are separated by a division wall having fire doors at all openings. Beneath the engine room are the storage batteries, extending partly under the sidewalk. Beneath the boiler room is space for coal storage, ash handling and the location of condensing apparatus and piping. The floor of engine room is laid with hexagonal tile, and the walls for 6 feet above the floor are wainscoted with marble. The main offices of the company occupy the Tenth and St. Charles street corner on the first floor. The private offices are in the second story, directly above. An elevator at east end of the boiler room runs from basement to third floor.

BOILERS.

There are four Heine boilers, Fig. 4, arranged in batteries of two each, with one stack between them, and economizers in the rear of and above the boilers. Each boiler has a rated capacity of 11,250 pounds of water per hour with feed water from the economizers at 200° F., into dry steam of 175 pounds pressure above atmosphere, and is guaranteed to be capable of developing continuously one-third more. Efficiency guarantee is 70 per cent of the calorific value of the coal at any load between rating and 20 per cent above. This is equivalent to evaporating 7.21 pounds of water per pound of Mount Olive nut coal of 10,600 B. T. U. The boilers are tested under a hydrostatic pressure of 250 pounds. The entrainment is guaranteed to be less than 1 per cent at rating, and not more than 1½ per cent at one-third above rating. A feature of the furnaces which is original with the engineers is making the firedoors open the full width of the furnace, greatly facilitating inspection and care of the fires. Two additional Heine boilers of the same capacity are now being installed.

Connected with the system is an improved draft gauge by which the draft can be read to thousandths of an inch at eight different points, including ash pits of four boilers, two breechings, inlet to draft fan and base of stack.

MECHANICAL DRAFT.

In order to counteract the effect of the economizers in cooling the gases from the boilers, and to permit crowding when necessary, a mechanical-draft system was installed. It is of the induced type, the fan being placed directly behind the stack and between the two batteries of boilers. The bearings of the fan are self-lubricating and water cooled. This fan is driven by means of a direct-geared electric motor, designed to be operated at different speeds on either the 235- or 470-volt circuit. The motor is to be controlled automatically, so as to maintain the steam pressure practically constant, the regulator slowing down the motor as the steam pressure rises and increasing its speed as the pressure falls. The capacity of the fan is sufficient to handle the waste gases from four boilers and furnish a draft equal to one inch of water where the gases leave the boilers. It is capable of being speeded in emergencies sufficiently to give a draft of 1½ inches on all four boilers.

FUEL ECONOMIZERS.

There are two Green fuel economizers, capable of heating regularly and continuously 45,000 pounds of water per hour 100° F. when receiving the water at 110° F., and with the temperature of the escaping gases leaving the boilers at not less than 450° F. One-third more water may be passed through in case of necessity, but

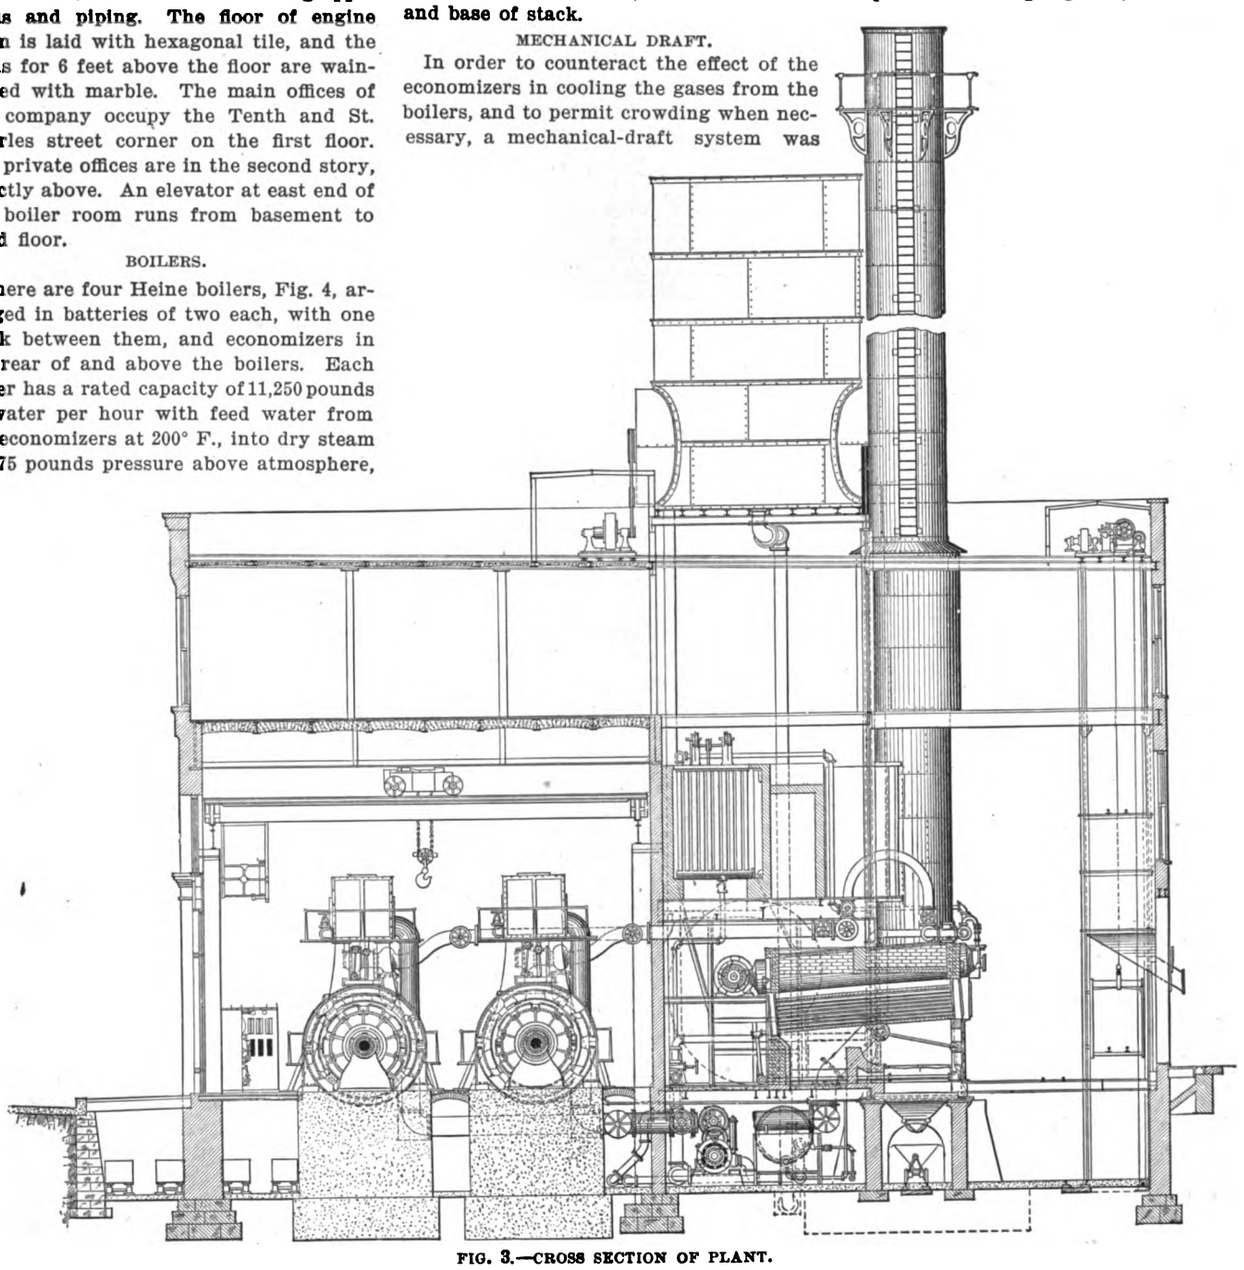

FIG. 3.—CROSS SECTION OF PLANT.

Digitized by Google

of course with diminished economy. These economizers are designed for a working pressure of 200 pounds per square inch, and were submitted to a hydrostatic test of 300 pounds after erection in position. They are provided with automatic scrapers operated by electric motors. The economizer plant is provided with pop safety valves, necessary deflectors, soot scrapers, doors, dampers, etc. They have pressure gages at feed-water inlet, also feed-water thermometers located one in pipe at entrance to economizers and one in pipe where water leaves the same; also two gas flue thermometers reading to 1000° F. in smoke flue; one where gases enter economizers, and one where they leave. The necessary dampers are provided for sending the gases from the boilers either past the economizers and directly out the smokestack or through the economizers and thence up the stack, or through the economizers to mechanical draft fan and thence up the stack. The economizers are located in the rear and above the boilers, supported upon a substantial iron framework and bricked in air-tight by 8-inch walls.

### COAL AND ASH-HANDLING MACHINERY.

The coal and ash-handling plant is of simple and economical design, and consists of a system of cars, tracks, elevator and overhead ash bin. The cinders and ashes from the lower grates drop directly into a metallic ash hopper under each boiler. Running east and west immediately under these hoppers there is a narrow-gage track. The ashes are dumped from these hoppers into small cars and pushed by hand along the track to an elevator, on which they are carried up and dumped into an overhead ashbin, from which they run by gravity into the wagons in the alley. Any ashes which accumulate in the stacks may be emptied directly in the cars in the same manner.

The entire space in front of the boilers in the basement is reserved for coal storage, the fuel being dumped through openings in boiler room floor. It is taken from this storage room in the same cars, tracks being provided the entire length of the coal storage space. It is then hoisted on the elevator to the floor above and distributed on tracks over the entire length of the boiler room in front of the boilers.

### STEAM ENGINES.

There are now in operation two engines, Fig. 5, of the Williams vertical two-cylinder cross-compound condensing automatic cut-off pattern, built by Wm. Tod & Co., of Youngstown, Ohio, and designed for direct connection to the dynamos and shafting. The east engine, No. 1, is of 750 i. h. p., and is designed for driving one 500-kw. generator at the most economical rating of the engine when operated at a speed of 150 r. p. m., and supplied with steam at 170 pounds initial pressure per square inch at the throttle valve, and exhausting into a 24-inch vacuum. Engine No. 2 has double the capacity, and is similar in design to No. 1. The heavy fly wheels are located between the A frames supporting the high and low-pressure cylinders. Each engine is so constructed as to be capable of operating continuously at double its rated capacity. and for short intervals only at one-third above its double rated capacity. This additional capacity is obtained by admitting live steam into the receiver or low-pressure cylinder. The high-pressure cylinders are steam-jacketed on the barrel, and both cylinders on both top and bottom heads. The receiver is provided with reheating coils of copper. The main bearings are adjustable, and are provided with water jackets. The guides are water-jacketed on the running side. The cylinders and all bearings are lubricated by the Siegrist lubricating apparatus, which delivers the two kinds of oil to the cups under pressure automatically maintained by duplicate steam pumps. They also have hand oil pumps for additional safety. The cylinders have flat multiported valves driven directly from the eccentrics. The clearance is guaranteed not to exceed 6 per cent in either cylinder. These engines are provided with shaft governors operating upon the valves of the high-pressure cylinders, and capable of varying the cut-off from 70 per cent of the stroke back to minus 3/16-inch opening. The regulation guarantees are that the drop in speed with a constant steam pressure from no load to one-third above rated load will not exceed 2½ per cent. This guarantee also covers a variation of steam pressure between 160 and 175 pounds with constant load. The variation of speed will not exceed 3½ per cent with the combined changes in load and steam pressure above specified, either with or without the vacuum. The governor is also fitted with a special speeding device by means of which the engine may be brought to the same rate of speed under friction only as under full load. When running with about 170 pounds pressure at the throttle, at 150 revolutions per minute and under a constant load at their rated capacity, the engines are guaranteed not to consume more than 15 pounds of water per indicated horse-power hour.

Another 1500-h. p. engine, designed and built by the Lake Erie Engineering Works, Buffalo, N. Y., has just been installed.

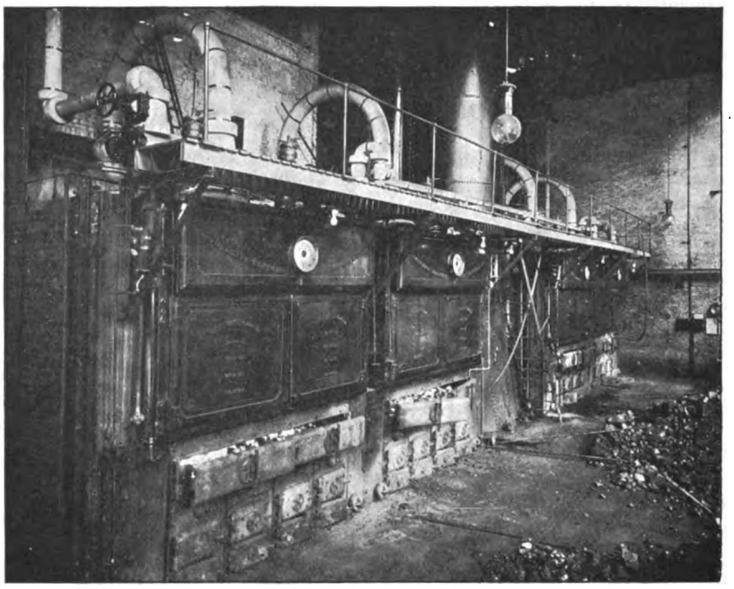

FIG. 4.—FRONT VIEW OF BOILERS.

### CONDENSERS, PUMPS AND COOLING TOWERS.

The condensing plant consists of one Worthington surface condenser, one Worthington cooling tower, two combined air and boiler feed pumps and two circulating pumps of the rotary type. The rated capacity of the plant is 33,750 pounds of steam per hour, but it will take care of overloads up to 49,500 pounds per hour with but slight reduction in vacuum. It is guaranteed to produce a vacuum of not less than 22 inches at above rating and under the worst conditions of service; 25 inches under fair and average conditions, and 26 inches under the best. These conditions vary with the humidity and temperature of the air.

The cooling tower, Fig. 7, located on the roof, is 18 feet in diameter, 29 feet high and its cooling surface is composed of galvanized iron pipe cylinders. It has duplicate fans located on opposite ends of the same shaft drawing air into the tower. These fans are driven by a belted motor in pent house on top of building.

There are two combined air and boiler feed pumps; one of sufficient capacity to handle the water required by the 1500-h. p. engine, and the other of sufficient capacity for the 750-h. p. engine, and two independent rotary circulating pumps of the same capacities. These pumps are driven by direct-geared motors, so designed that the speed may be varied at least 33 1/3 per cent.

There are also two injectors for reserve boiler feeds, each having a capacity of 11,250 pounds of water per hour, and capable of handling water of any temperature below 125° F.

Digitized by Google

POWER TRANSMISSION SYSTEM.

The engines and generators are connected by means of the Arnold system of power transmission (see Fig. 5), consisting of quills and internal shafts with double bearings, connected by magnetic clutches. The arrangement is intended to make it possible to drive any one, two or all three of the 500-kw. generators, and either one or both of the boosters, from the large engine in case of accident to the small engine. Two generators and one booster may also be handled by the small engine in case of accident to the large one.

The generators are connected to the engines by means of magnetic couplings, so arranged that either intermediate generator or booster may be disconnected from one engine and connected to the other while all are in motion. When it is desired to start up a generator, it is brought up to speed as a motor and then connected to the engine by the magnetic clutches.

PIPE WORK.

The entire high-pressure system is designed to operate under a working pressure of 175 pounds per square inch, and was tested to 250 pounds hydrostatic pressure. All fittings are extra heavy. All pipe above 3 inches in diameter has flanged couplings and fittings. All bent pipes are made of steel, and bent hot and of long radius. All valves on live steam pipes and on the feed water connections under boiler pressure are bronze seated. All valves above 10 inches in diameter are by-passed. The cylinder jackets, re-heaters, separators, steam headers and the entire pipe system is drained by means of the Holley system, returning the water directly to the boilers. There is a combined hot well and oil filter located between the condenser and boiler feed pumps. All the pipes are covered with magnesia. A steel exhaust pipe is provided for use when condensers are not in service, and extends through the roof near the stack. Each engine has a Cochrane separating receiver located near the main throttle valve. Oil extractors are located between exhaust pipe and condensers. A suitable blow-off tank is provided and connected to boiler furnaces, oil extractors and other hot water drains, with suitable discharge to catch-basin, which in turn overflows to sewer.

CRANE.

The engine room is spanned by an electric traveling crane (shown in Fig. 5) with independent motors on the lifting, traveling and transfer motions. The capacity of the crane is 15 tons at 10 feet per minute, and it has a maximum speed of 30 feet per minute at lighter loads. The maximum speed of travel is 80 feet per minute, and the maximum transfer speed 40 feet per minute. The motors are of 20, 15 and 5 h. p. respectively, and are designed by the manufacturer as a part of the crane and built substantially into the framework of the structure. This crane has proved itself one of the most useful appliances about the plant.

GENERATORS AND BOOSTERS.

There are three 500-volt generators, built by the Siemens & Halske Electric Company of America, of the internal iron-clad-armature type. They are designed specially to fit the system of power transmission adopted. The field frames of the generators may be slid parallel with the shaft a sufficient distance for reaching the armature for repairs. The capacity of each generator is 500 kw. at 525 volts when operated at 150 r. p. m. At this rating the rise in temperature of the armature will not exceed 40° C.; of the field, 35° C.; of the commutator, 50° C. The generators are guaranteed for an overload of 25 per cent. for two hours, and 33 1/3 per cent for one hour, with a 50 per cent momentary overload without injurious sparking. They will not flash at the commutator when the circuit breaker opens at 50 per cent overload. The commutators are of large diameter, insulated with mica and designed for carbon brushes. The brushes are proportioned for 25 amperes per square inch of contact with rated load and have hand wheels for both adjusting and lifting. One megohm of insulation resistance is specified between conductors and frame. The guaranteed efficiencies of these generators are as follows:

| | |
|---|---|
| At ¼ load | 88 per cent. |
| At ½ load | 92½ " |
| At ¾ load | 93½ " |
| At full load | 94 " |
| At 25 per cent. overload | 93 " |

There are two separately-excited shunt-wound boosters, each of 50-kw. capacity at 150 r. p. m., and capable of carrying 500 amperes and delivering any voltage from zero to 130 volts. The boosters are of the same general construction and design as the generators, except that the field frames are divided vertically. Two more generators of the same capacity are being made at present by the same company.

SWITCHBOARD.

The plant contains a composite switchboard, Fig. 6, of 2-inch black marbleized slate, containing three generator panels, one booster panel, two battery panels, one wattmeter panel, three feeder panels and one voltmeter panel.

There are four bus bars on the switchboard; one high positive, one low positive; one high negative and one low negative. There are also positive and negative charging buses. The generators are so arranged that each generator may be operated on either high or low bus bars, either in multiple or separately. Each of the two end-cell switches on each end of the battery may connect either to the high bus or low bus, or to the charging bus. The two boosters in the plant may each be connected either between high bus and charging bus, low bus and charging bus, or between low bus and high bus, on either side of the system. The boosters may be connected in series either between low positive bus and neutral or between low negative and neutral. These combinations provide for charging the battery under all conditions of service, and at the same time maintaining it upon the line as an equalizer of the pressure. Also, either side of the battery may be completely disconnected, or the entire battery cut out of service and the balance of the system maintained by means of the two boosters connected together in series and operating between the neutral and either side of the system.

All the electric connections between generator and booster and switchboard are made of asbestos-covered copper cable run underneath the floors and supported upon porcelain holders. The connections between battery and switchboard are made by means of copper bars, lead-covered and painted with an acid-proof paint, and supported upon porcelain racks. The battery is connected through switches to the bus bars and outside circuits without the intervention of either fuse or circuit breaker. Two additional generator panels of the same design have lately been added to take care of the additional dynamos contracted for.

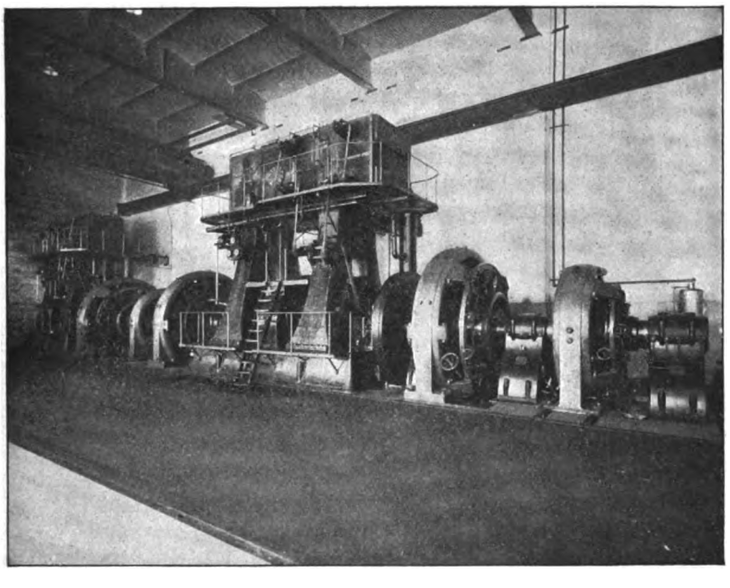

FIG. 5.—ENGINES, DYNAMOS, BOOSTER, MAGNETIC CLUTCHES AND CRANE.

STORAGE BATTERY.

There are 280 cells of the Electric Storage Battery Company's accumulators, each containing thirteen positive Manchester type plates and fourteen negative chloride plates. These are contained in lead-lined wooden tanks which are supported on large porcelain insulators resting upon 4x6-inch beams. The capacity of this battery is 2000 ampere hours at a discharge rate of 250 amperes, and it is capable of maintaining a maximum discharge rate of 1000 amperes for one hour. It is guaranteed to give a discharge of 500 kw. for one hour without a drop in pressure below 1.7 volts per cell. The normal charging rate is 250 amperes, and the maximum charging rate 350 amperes.

The battery as mentioned above is located in the basement, partly under the engine room, partly under the sidewalk, in a cool, well-ventilated room. The floor is composed of vitrified tile laid in pitch upon a concrete base.

CONDUIT SYSTEM.

Many were the criticisms hurled at the heads of the city officials when they declared that all of the high-tension electric companies should occupy jointly a single conduit system. However, the city proceeded upon this line, and issued conduit rights to all the high-tension companies to the ownership of so many ducts each in a joint underground conduit system occupying one side of the street. On the opposite side the low-tension conduits of the telegraph and telephone companies were placed.

It was feared that the joint building, ownership and maintenance of a conduit system by the high-tension companies might lead to endless litigation, but a liberal application of the golden rule to the grouping of ducts and to the location of service boxes and other engineering details of the work has produced a system of underground conduits which we believe has few, if any, equals.

The high-tension conduit system consists of 3-inch cement-lined pipe laid on 5¼-inch centers, with one inch of concrete between pipes and 3 inches surrounding the entire group. All ducts are laid to drain to manholes. The top layer of ducts enters service boxes, which are of two sizes, 3x3 feet and 3x4 feet. Service boxes are placed at most convenient points for reaching customers, and their depth is governed by the depth of the conduit at each location. Manholes located at every street intersection, and oftener where necessary, are of three sizes, 4x4 feet, with 9-inch walls; 5x5 feet, with 9-inch walls, and 8x8 feet, with 13-inch walls. In depth they are all designed to be 6 feet 6 inches in the clear under the roof. They are connected to sewers wherever sewers could be reached.

The conduits of the Imperial Company as a rule occupy every other street in each direction. They were laid out with the object in view of being able to reach one end of every alley in the city with the distributing main. It was the intention to build service boxes only opposite the entrance of alleys and to distribute entirely through the alleys either by overhead pole lines or through underground distributing laterals. The entire distribution system consists of two ducts, providing one duct for a three-conductor cable and one extra duct for city lighting or other service in the future.

Where feeders were located the number of ducts was increased to provide for them. The system as planned provides for feeders of sufficient size so that one of the largest cables would fill one duct, taking a single cable for the positive and another for the negative sides of the system. A third duct would contain the neutral feeder and pressure wires; another duct to contain the three-conductor main cable, and one duct reserved for future service.

UNDERGROUND CABLE SYSTEM.

While the conduit system provides space for a total of twenty-three feeders, there have been five installed at present. Each feeder consists of two 1,500,000 c. m. single conductor cables and one 500,000 c.m. single-conductor cable for the neutral wire. A pressure wire of No. 16 three-conductor cable carried in the same duct with the neutral, and connected to the ends of the feeder, provides means for measuring the pressure at the feeding point by a voltmeter located at the plant. It will be observed that the feeder cables have all the same carrying capacity, notwithstanding the fact that some are nearly twice the length of others. The object of this is to economize conduit space and cost of cables by using the largest cable that can be conveniently pulled through a duct. Provision is made at the plant for keeping the pressure at the ends of all these feeders approximately equal, regardless of their length and the variation in drop, by running different voltages at the switchboard.

Each of these feeder cables connects to a single-pole double-throw switch on the switchboard without the introduction of any fuses or circuit breakers. Each feeder goes through two feeder testing boxes placed at convenient distances along its length, and at the end connects to the system of mains through copper fuses located in the junction boxes.

The mains are composed of three conductors, each of the same size, to provide for better distribution of pressure. The rubber tape surrounding each conductor was made of a distinguishing color for convenience in connecting, and very few errors of this kind were made in connecting together the entire system. At several points junction boxes were placed, which are shown in detail in Fig. 7, into which these three-conductor mains were run and connected to bus bars through copper fuses. These fuses are each provided with a small porcelain knob for convenience and safety in handling while fusing up or disconnecting. The lead sheaths on the mains were divided and brought up through the bottom of the junction boxes and sealed water-tight by means of special stuffing boxes. The lead joint at the point of division outside the box was wiped water-tight. The cover of the junction box is screwed tight upon a rubber gasket by toggle bolts, making a thoroughly water-tight box.

The lateral service cables connecting from the underground mains to the basement of the customers' buildings are similar in design to the three-conductor mains, differing only in size and corresponding variation in thickness of rubber and lead. They are joined to the mains in the service boxes by means of a three-conductor soldered joint, which is carefully insulated with rubber, thoroughly taped and protected by a cast-iron box. This box is then filled with an osokerite compound, thoroughly insulating and preserving the joint from all contact with moisture or other deteriorating substance. The

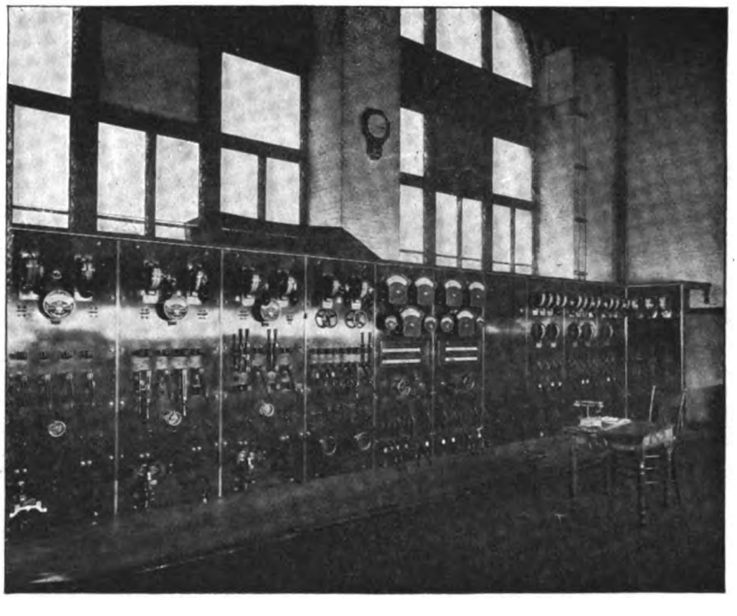

FIG. 6.—SWITCHBOARD.

Digitized by Google

insulation resistances of these cables were guaranteed as follows:

No. 16 B. & S. three-conductor, 1000 megohms per mile.
No. 0, 2-0 and 250,000-c. m. three-conductor, 750 megohms per mile.
500,000-c. m. single conductor, 500 megohms per mile.
1,500,000-c. m. single conductor, 400 megohms per mile.

For a break-down test the entire system was submitted to 3000 volts alternating current, and found to withstand this test satisfactorily. The insulation guarantees were also found satisfactory under accurate tests.

The insulation resistances were all measured by means of the capillary electrometer designed by H. C. Burgess, of the University of Wisconsin and described by him at the Omaha meeting of the A. I. E. E. The results were found to be highly satisfactory. It is an extremely sensitive instrument, but is unaffected by magnetic influences or by the jarring of building. The voltage used throughout most of the tests was 100 volts, obtained from a chloride of silver battery. Attempts were made to use a dynamo current from the local power circuits, thus making the test at 500 volts the maximum pressure intended to be carried in use. The attempt was a failure, due to the unsteadiness of the local power circuit and the consequent disturbance due to condenser effect in the cables.

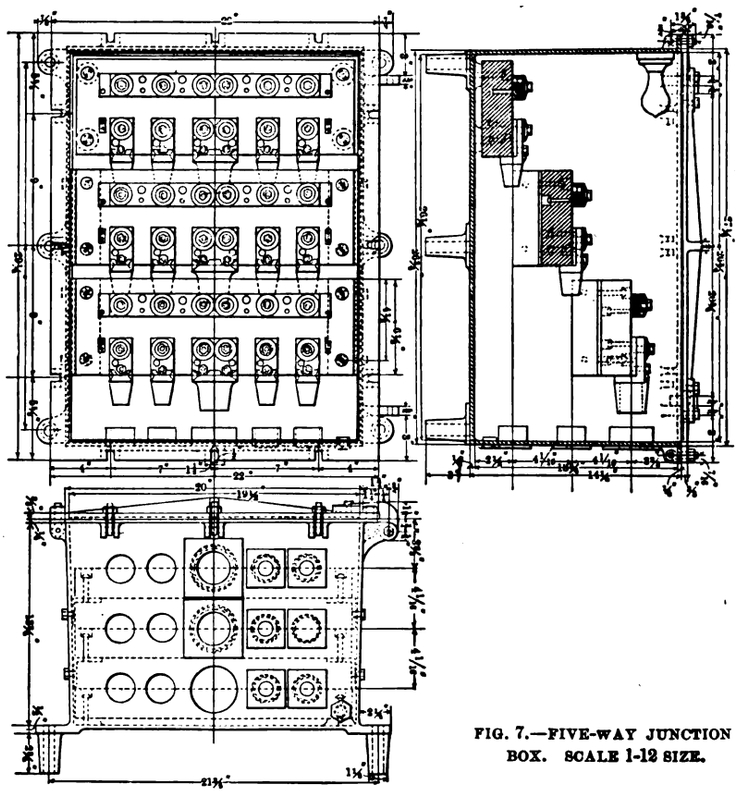

FIG. 7.—FIVE-WAY JUNCTION BOX. SCALE 1-12 SIZE.

### INSIDE WIRING.

The entire inside wiring is done on the two-wire multiple-arc plan. The lateral cables entering the basements of the customers' buildings are three-conductor cables, furnishing either 235 or 470 volts. All electric power service is connected to 470 volts, and the inside wiring is run open and supported on porcelain knobs, with rubber-covered wire. The incandescent and arc lamp wiring is taken off one or the other side of the system at 235 volts and run with rubber-covered wire either on porcelain knobs or cleats or concealed in an approved conduit system. All of the old-style 110-volt cut-outs were replaced. Specially designed tablet boards with terminals properly spaced for the higher voltages, and with inclosed fuses, were used throughout this work. All of the old sockets were replaced with the latest design in porcelain sockets, and where defective cord was observed it was replaced by an approved rubber-covered flexible cord. All of the inside wiring having been gone over in this way, and cleared of grounds and brought up to the latest standard of practice, has resulted in decreasing, rather than increasing, the fire risk following the introduction of the higher voltage system.

### INCANDESCENT LAMPS.

The incandescent lamps used on this system are of the 235-volt type, mostly of 16 c. p. are in use; also small candle power decorative series lamps. The lamps are all Westinghouse cap and porcelain base. The filaments are either double, two in series, or coiled in several convolutions. This characteristic is due to the extra length necessary on a lamp of this voltage. The lamps were bought under guarantees regarding efficiency, life and the maintenance of candle power, which were entirely satisfactory to the purchaser. In practical operation the light has been entirely satisfactory to customers, and they compliment the character of incandescent service furnished. There were at first minor mechanical and electrical defects, however, such as the sagging of the filament until it touches the glass where lamps are not placed in a vertical position, and the short-circuiting of leading-in wires when a filament burns out near its support, all of which have been remedied in later lamps. There have, however, been no accidents or fires resulting from these causes.

### ARC LAMPS.

In the original design of this plant, begun fully three years ago, it was anticipated that its principal business would be power service, and that arc lighting would not exceed 15 per cent of the total service. The introduction, however, of the inclosed arc lamp and its remarkable popularity, due to the steadiness of the light and the facility with which its service is metered, has so increased the demand for arc lighting that the arc service is at present a very important part of the company's business. It was believed at the time that the plant was designed that arc lighting might be made secondary to both the incandescent and motor work. The 235-volt inclosed arc lamp was therefore adopted on account of its convenience, one light being controlled independent of all others. It has been found by experience that two arc lamps burning in series on 235 volts give better service than the single lamp. In cases where a single lamp must be used a satisfactory light has been obtained by increasing the current to 3½ amperes.

### MOTOR SERVICE.

The entire power service is taken from the outside wires of the system at 470 volts. These wires inside of the building in all cases are treated as high-tension circuits. It might be surmised that complaint would be made regarding the power service on account of this reduction of voltage on 500-volt motors. This has not proved to be the case. The motors having been previously used upon systems varying in voltage from 450 to 550, the users of power were educated to expect a considerable variation in the speed of their motors. With a steady pressure of 470 volts at the motor terminals, none of the company's customers have complained regarding their power service.

### LOAD CURVE.

The load curve shows one of the great advantages of the storage battery. The entire plant is shut down from one o'clock until five in the morning, and the load carried upon the battery. The machinery is then started and the battery charged during the forenoon, allowed to float upon the system during the afternoon and discharged during the peak in the evening; and again charged considerably during the first half of the night before shutting down. Interesting features are the large all-night load and the comparatively low peak or maximum load. The average output for twenty-four hours is 2198 amperes, which is 39.27 per cent of the maximum load.

### SPECIAL FEATURES.

The distinguishing features of this plant which marked it as advanced engineering practice are:

Digitized by Google

First. The 220-440-volt system of distribution.

Second. The entire system is underground.

Third. The battery equalizer and auxiliary.

Fourth. All subsidiary apparatus is electrically driven.

Fifth. Fuel economizers with induced mechanical draft.

Sixth. Condensing apparatus with cooling tower.

(a) The wisdom of selecting the double voltage system will be appreciated when it is stated that the saving in copper alone in the district covered by this plant is equal to half the cost of the building and entire station equipment. This system was almost unknown at the time of its adoption here, but several plants using it have since then begun operations in Europe, and another large installation is being erected in this country. The system is reliable, safe and satisfactory in its service to the public.

(b) The undergrounding of all wires is the ideal method of distribution as regards public safety, reliability of service and low depreciation and repairs.

(c) The value of a storage battery as an equalizer of pressure and as an auxiliary to the steam plant is universally admitted. It has proved indispensable on many occasions in this plant. Its readiness to take all burdens thrown upon it, whether accident to plant, short circuit in underground cables or sudden demand for light caused by a thunder storm, needs only to be experienced to be appreciated.

(d) Driving all boiler feed, circulating and air pumps, elevator, fans, etc., by electric motors saves the condensation in all subsidiary steam pipes, as well as avoids the wasteful use of steam incident to this class of apparatus. By using steam only in the large cylinders of the condensing engines and driving all minor apparatus by motors, it is estimated that a saving of about 10 per cent. on the entire output of the plant is utilized.

(e) Fuel economizers give all the water entering the boilers an additional temperature of 100 degrees F., which effects a saving of about 9 per cent. in the use of fuel. With coal at $1.50 per ton, they will earn annually about 25 per cent. on their cost.

(f) With losses deducted, it appears that condensing apparatus as here employed make a saving of from 15 to 20 per cent. in fuel, thus earning a large return on its cost.

The entire station equipment was included in one contract, under rigid guarantees from the contractor covering the efficiency of the plant as a whole. A definite cost of coal per kilowatt hour delivered to outside circuits from the switchboard was guaranteed under a forfeiture in case of failure, with an equal bonus for increased efficiency above the figure specified. It was intended to give in this paper the results of these tests, but, as they are not completed, no report can as yet be made.

## THE DESIGN OF FUSIBLE CUT-OUTS.

BY BENJ. H. GLOVER.

Speaking from the standpoint of the fire underwriter, the proper design of cut-outs is an important subject, inasmuch as a very considerable fire waste has been, and continues to be, occasioned through the faulty construction and design of these fittings. All tests and treatments have shown the common cut-out to be subject to such variations and modifying influences that but little of practical value can be deduced from analytical investigations.

In the earlier days of electric lighting, wooden bases were used, but were soon abandoned, due to continual trouble with "grounds" and "shorts" resulting from absorption of moisture and the loosening of contacts, and charring, due to the combustibility of the wood. Porcelain is now almost universally used. The base and cover being much the larger portion of a cut-out, the porcelain manufacturer has taken it upon himself to design and sell these goods. Important electrical details are often sacrificed for convenience in getting out the porcelain, and "any old thing will go" seems to be the motto followed in some cases, no regard being paid to the various and excessive demands made upon the product.

The subject of glazed and unglazed porcelain in itself opens up a large field for discussion. A glaze with an excessive coefficient of expansion will in time become full of cracks or become "crazed," as the porcelain manufacturers express it. These cracks retain moisture and offer paths of comparatively low resistance between terminals of opposite polarity or to ground. The use of lead in the glaze usually results in a metallic film upon the blowing of a fuse. The parts of a cut-out about the fuse itself should preferably be left unglazed. The fuse should not be in contact with any surface of the base. If supports between the terminals are necessary they should be in the form of transverse ribs with smooth rounded tops.

While an air space is desirable about the fuse the ends of the block should not be left entirely open. As a fuse usually ruptures at or near the center the aim should be to provide a proper vent at this point and still retain sufficient pressure to cause a blow-out of the metallic vapors and suppression of the arc formed. For these reasons a rather restricted air space at the ends and an enlarged air chamber with vents near the center of the fuse give more reliable action. A cover for the base should always be used. The fire risk is made less and the sensitiveness of the fuse is increased especially for small sizes.

The Terminals.—Terminals are universally made of brass in the form of stampings, castings or sections of square or round bar. The following modes of connection to the wires have been noted: a screw; a screw and washer; a screw with one upturned lug on terminal, with and without washers; a set screw; two set screws; an angular bottom piece with a clip above held by one or two screws; double clips with a center V groove, and several others.

In the construction of switches it is considered quite proper and necessary to provide lugs, firmly bolted or screwed to the switch, into which the conducting wires shall be soldered. This applies to switches of over 25 amperes capacity. If this is necessary for switches and bus bars and in making connections to dynamos and motors, why is it not so for cut-outs?

Connections for currents up to 25 amperes should be made to terminals provided with screws and washers with a turned up lug on both sides to prevent the wire from slipping out. When the capacity of the cut-out exceeds 25 amperes connections should be made with lugs, firmly screwed to the terminals on a flat surface, and into which the conducting wires can be soldered. This may seem like excessive care, but when it is considered that very appreciable losses are due to the many poor contacts and connections made in a circuit, too much attention cannot be given to this matter of contacts. The terminals should be set in from the ends of the blocks so that live portions of the circuit will not be exposed.

The proper distance between terminals has long been a disputed question. A catalogue of a well-known manufacturer of these goods shows for 110-volt circuits break distances of from ¼ inch to 2½ inches. He no doubt strikes the correct length somewhere. An engineer of a prominent company stated two years ago, "We are redesigning our link cut-outs so that the fuse metal tips shall be fully 1 inch apart. Some of our cut-outs are much less than this, and we believe it is safer to have a longer break distance than what we are now using." A well-known Chicago engineer said a few years ago, "I have always felt that the emphasis of experimental evidence should be directed to convincing the people of the advisability of using long fuse blocks, thereby contributing to the reliability of such protecting devices."

There are many goods on the market with a ½-inch break distance between terminals. A current of 20 amperes will invariably establish a vicious arc between terminals at this distance, and the terminals will frequently melt with explosive violence. The terminals are not only fused but often the entire base and cover are shattered into fragments. Such results are aggravated by the enormous capacity of our modern central stations in populated districts.

For a given fuse, blown in a given time, there is a critical length. Careful experiments have shown that these lengths are as follows:

| | | | |
|---|---|---|---|
| For 3- 5 amperes | . | . | 2½ inches. |
| 10-15 " | . | . | 3½ " |
| 20 " | . | . | 4 " |

Or for each 5 amperes an increase in length of one-half inch.

These lengths seem excessive when

Digitized by Google

judged by common practice, but the data clearly indicates where practice might be improved.

Realizing that extended reforms cannot be instituted at once, the rules of the National Electrical Code specify one and one-quarter inch break distance between terminals for 110 volts, and 2½ inches for 220 volts. The fuses to be held free from contact with the base and be provided with tips of hard metal. In the open type of cut-out, the terminals usually have a greater distance between them than in the covered style, but a serious fault in their design is that the terminals are set in flush with the surface of the porcelain. Terminals should be secured to the base by at least two screws so as to prevent turning and loosening. Screw heads on the back should be countersunk and the heads covered with a moisture-proof and insulating wax or compound. These points should go without saying, but an inspection of stock being sold shows that there is neglect along these lines.

The Fuse.—The ordinary fuse is made from an alloy the greater part of which is lead. This alloy is used in the form of wire, wire links or strips. The opening of the circuit is caused by the melting of the fuse. The necessary heat is obtained from the energy developed in the fuse by the current. But the blowing of a fuse is not immediately an electrical act. The current fuses the metal, the cross section is reduced at some point due to gravity, unequal expansion or "sweating," the heat intensifies at this point and a globule falls, breaking the circuit and establishing an arc, which soon burns out a length of the fuse. The time required for this action may vary between considerable limits under different conditions. In some cases this fact is an advantage, while in others it might be fatal.

A combination intended to increase the accuracy of operation and to reduce to a minimum the radiation and conduction of heat is found in the enclosed fuse.

A fibre tube is filled with a porous powder and the fuse is soldered to the brass ends of the tube, being embedded in the powder except in the center of the tube where a small capsule forms an air chamber. These fuses will operate at a predetermined point for any overload and can be relied upon within very close limits. An objection has been made to their use as there is no exterior indication to show when a fuse has opened.

A new design is about to be put on the market with the object of overcoming this objection. It consists of an enclosed fuse with a shunt of fine high-resistance wire between the terminal on the outside of the fibre tube. The blowing of the fuse diverts the current through the shunt wire, which immediately blows and serves as an outside indicator.

For sudden heavy overloads a multiple fuse of several small wires is much more sensitive than the one large one of the same capacity. For the same reason a thin, flat ribbon may be considered more reliable than a round fuse.

# Among our Foreign Contemporaries

**A Means of Paralleling Alternators.**—In throwing one alternating-current machine in parallel with another difficulties are always found in getting the two to run at exactly the same speed. If their governors are properly adjusted to each other they will run at the same speed when both are loaded, but if one is loaded and the other is light the loaded machine will be running at a slightly lower speed than the other. To throw in a fresh machine in parallel with others loaded the fresh machine must be slowed down in some way to the speed of the others. In the early days of parallel working this was done in foreign plants by putting an artificial load

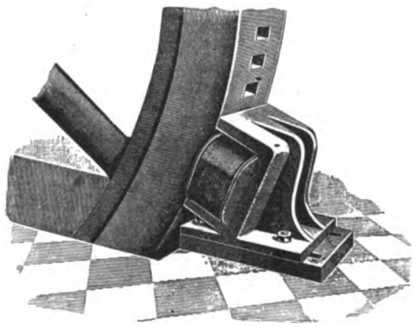

FIG. 1.—A BRAKE FOR USE IN COUPLING ALTERNATORS.

of lamps upon the fresh machine. It was then thrown in parallel with the others, after which the artificial load was cut out. In this country the speed is commonly lowered by throttling at the main stop valve, or the governor is fitted with an arrangement for temporarily reducing the speed at which it will tend to run the engine. An artificial load somewhat less crude than the big bank of lamps is used to a certain extent in Germany, and was described in a recent paper by G. Dettmar in the "Elektrotechnische Zeitschrift." The load consists simply of a magnet facing the rim of the fly wheel, as shown in Fig. 1. By exciting this magnet very powerful foucault currents are set up in the rapidly revolving fly wheel rim, absorbing sufficient power to slow down the engine to synchronism with the other engines loaded. The machine is then thrown in and the magnet de-energized, relieving the fresh machine of its artificial load and allowing it to pick up its share of the useful load. The artificial load of course generates considerable heat, but this is distributed throughout the fly wheel rim so that in the short time during which it is in use there is no great rise of temperature.

---

**High-Pressure Low Candle-Power Lamps.**—In a letter to "The Electrician," London, Mr. Alfred H. Gibbings, Electrical Engineer to the City of Bradford, makes the following statements: "I may say that, owing to our free supply of incandescent lamps for renewals, which amounted to over 9,000 last year, we have been led to look carefully into the respective merits of almost every incandescent lamp which is imported into this country. We have tested about 30 different makes, both for life, uniformity of candle power and efficiency, and there can be no question that at the present time the majority of manufacturers make equally as good if not better 200-230-volt lamps for all candle powers that was the case when 110-115 volts was the standard voltage." The same is very far from true of lamps made in this country, and the conclusion is inevitable that, compared with American standards, either the high-tension lamps imported into England are very good or low-tension lamps were very poor.

---

**A Novel Means of Fastening Conductors on Smooth-Body Armatures.**—In an article on "Low Voltage Dynamos," contributed to "The Electrician" of London, Mr. E. K. Scott argues in favor of machines in which the commutator bars form part of the armature windings as they do in the Siemens & Halske outside armature type. For electro-metallurgical machines which are liable to short circuit it is important to keep the field relatively strong, and this is best secured by having a smooth body armature and a long air gap. At the same time it is important that the bars should be held very securely on account of their having to take suddenly varying tangential pulls. On the machines for the Falls of Foyers the Oerlikon Works have adopted the detail of construction shown in Fig. 2. As this indicates, brass plates ⅛ in. in thickness are interspersed be-

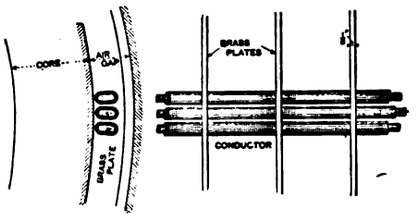

FIG. 2.—A MEANS OF FASTENING CONDUCTORS ON SMOOTH-BODY ALTERNATORS.

tween the armature laminae at intervals. These brass plates go in as far as the spider and extend out beyond the laminae and almost to the pole pieces; holes are punched in the plates just large enough to take the micanite tubes surrounding the conductors. In this way a long air gap is obtained, and yet each conductor is positively driven just as well as in toothed armatures.

**An English Safety Valve.**—In English boiler practice the spring actuated "pop" safety valve is comparatively rarely, if ever, found, their safety valves being as a rule loaded by dead weights and not capable of being locked against overloading as are American types. The English valves are also made to respond to either high or low water level in an ingenious way, which is illustrated in Fig. 3, reproduced from "The Practical Engineer." Here the valve is of the closed type fitted with a flanged opening for connection to an exhaust outside the building. The valve disc is an inverted cup closing against the seat shown at S. The upper end of this cup rises through a bearing in the enclosing case and supports a heavy inverted cup-shaped casting, C, on which may be placed any desired number of ring-shaped weights, W, the number of weights being varied according to the working pressure of the boiler. The valve disc is guided by the bearing in the case by lugs, which the illustration shows immediately outside of the valve seat. The response to high and low water is obtained by means of the floats shown below in the boiler. These are connected with a lever which operates a rod passing up within the cup of the valve. In case the water level falls below the normal position of the low-water float or above the position of the high-water float, this rod is pushed up until a nut upon it lifts the valve off its seat and allows the steam to escape. An extension of the same rod apparently operates the valve of a whistle mounted on top of the safety valve, this whistle giving notice of the abnormal condition of the water level before this condition becomes so extreme as to raise the safety valve.

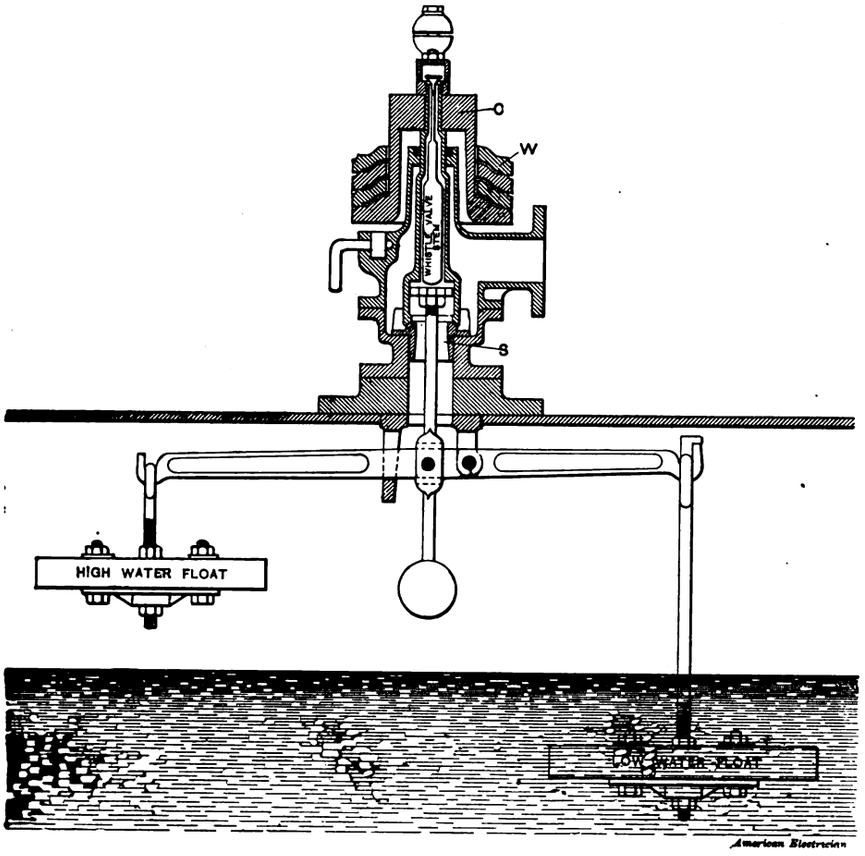

FIG. 3.—A HIGH OR LOW WATER SAFETY VALVE.

**An Electrolytic Method of Sharpening Files.**—Mr. Sherard Cowper-Coles contributes a note on this subject to the "Electrical Review," London. The cutting edges of a file can be readily sharpened by dissolving off a thin and even film of the steel. Among experiments which were made for the purpose of determining the best conditions, current densities were tried varying from one to 500 amperes per square foot, and a large number of electrolytes were tested. The best results were obtained with a solution of ferric chloride and high-current densities, averaging about 500 amperes per square foot, and applied for 15 minutes.

**Another Possible Electric Lamp** —In a paper recently read by Mr. A. A. Campbell Swinton before the Philosophical Society of Glasgow an experiment was described in which a light of several hundred candle power was obtained with less than one watt per candle and at a very high pressure, 8000 volts. The light was obtained from cathode rays which are the bombardment of the highly attenuated particles of matter in a highly exhausted tube. These rays were concentrated at one point, setting up there an extremely high temperature comparable with that of the electric arc. By using a disc of thoria, one of the emissive substances used in Welsbach mantles, the high temperature obtained gave a highly efficient light.

**A Novel Method of Transporting Freight on Electric Railways.**—The Bessbrook & Newry Electric Railway in Ireland handles ordinary wagons, which, when they leave the electric line are drawn, as usual, by horses. The wagons are not transported on trucks or flat cars, but are simply run on a track of flat rails placed immediately outside the regular tee rails for the cars. The gage of the cars is such that the tee rails serve as a guide to the wagon wheels. The system allows freight to be transported without rehandling or without terminal charges and with comparatively little delay at the transfer points.

**Large Steam Turbines.**—The largest steam turbines in the world are two of some 1400 h. p. capacity each, being built by the English firm of C. A. Parsons & Company for a municipal lighting plant in Elberfeld, Germany. The machines are of the standard Parsons type and are coupled directly to four-pole alternators designed to give 250 amperes at 4000 volts or 1000 kw. The speed is 1500 r. p. m., giving a frequency of 50 cycles per second.

**Losses at Brushes in Testing Dynamos.**—In a long discussion on the question of testing dynamos and determining the various losses, in the German journal, the "Elektrotechnische Zeitschrift," Mr. Fischer-Hinnen contributes some matters of interest, and as he has had considerable experience in the construction of dynamos his conclusions can no doubt be accepted as good practice. He also confirms the statement about which there has been some discussion recently, namely, that the friction losses in a machine at a constant speed increase with the excitation, and quite appreciably so; this is of importance in certain methods of testing dynamos for their efficiency. He attributes this to the attraction of the armature by the magnets, due to the fact that the armature may be slightly eccentric. The effect of this side pull is specially great when the machine is started, and the frictional coefficient in that case may be from 8 to 10 times that at normal speed, a matter which may be of importance in connection with traction motors. Incidentally he states that the losses due to hysteresis and Foucault currents increase quite appreciably with the load on the machine. Concerning the losses at the brushes he gives some simple formulas and data; these losses, even in approximate determinations of the efficiencies, are not to be neglected. With the usual machines of 100 to 125 volts, the losses are approximately as follows: For metallic brushes the losses due to the Joule effect (that is, the loss which is

Digitized by Google

equal to the square of the current multiplied by the resistance), are from 0.4 to 1.2%, and those due to friction, from 0.2 to 0.5%; with carbon brushes these figures are 1 to 2% and 0.5 to 1% respectively. The total loss will be least when that due to the Joule effect is equal to the friction loss, both, of course, being given in the same terms. For the cross section of the brush in this case, in which the total loss is a minimum, he gives the following formula

$$S = \frac{0.21}{\sqrt{v}} \frac{C}{p}$$

for metallic brushes, in which S is the cross-section in square centimeters, v the surface speed of the commutator in meters per second, C the total armature current, and p half the number of circuits in parallel; in an ordinary armature in which there are two such circuits the value of p would simply be unity. For carbon brushes the formula is the same except that the value of the constant is 0.68. For the minimum total loss at the brushes in watts he gives the following formula

$$W = 0.39\ C\sqrt{v}$$

for metal brushes; for carbon brushes the formula is the same except the constant is 1.19. For medium large machines of 20 to 60 kw. at about 100 volts, having two to four brushes, it is not always easy to give the brushes the cross-section required by the above formula, and in that case the loss will be greater than that given in the second formula. For a surface speed of 8 meters per second the total loss due to the brushes will be greater than 0.8 to 1% for metallic brushes, or for carbon brushes greater than 2.5 to 3%.

# Some Recent Electrical Patents.

**A Laminated Pole Dynamo.**—In most dynamo-electric machines with laminated poles it is customary to make at least the field yoke ring solid, the polar laminations being either cast into the yoke ring or bolted to it with a finished joint. Mr. Robert Lundell describes a machine in which the whole field is constituted of C-shaped iron or steel laminations. One of these is shown separately in the small view at the right hand side of the accompanying cut, the method of assembling them being shown in the larger view which is an end elevation of the machine. The ends of these stampings or laminations, which project inwardly toward the armature and constitute the poles, are surrounded as usual by the field coils, and between the laminations

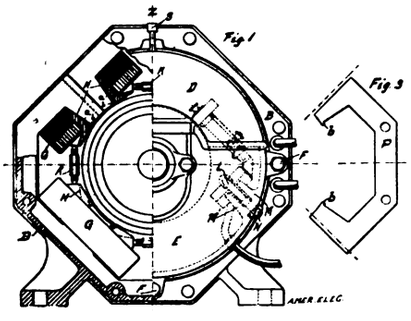

FIG. 1.—A LAMINATED POLE DYNAMO.

and the coils are cast-iron polar extensions H, which serve a triple purpose of holding the laminations together, of retaining the coils in place and of providing pole horns of a permeability lower than that of the pole center and thereby giving a commutating field through a material saturated at no distortion and therefore not seriously affected by a distorting tendency. These polar extensions are caught by catches b projecting into notches a and are further held by jack-screws K. Patent No. 626,496.

**A Compound Telephone Circuit.**—A good illustration of the available multiplicity of combinations of telephone apparatus is the patent issued to T. C. Burgess and H. W. Wilder, describing a means of making one telephone responsive to either of two others which are not in communication with each other. The combination is designed for exchange operators whose head sets should be in an order wire or instruction circuit and yet who should be able to cut in to subscribers' circuits when they so desire. The design is such that the order wire connection remains in the operator's head set but no conversation can cross from the order wire to the subscriber's circuit. The elements of the circuit are shown in the accompanying diagram, in which the apparatus at the right hand side is the operator's telephone, and t represents a microphone supplied by the battery, b, through the primary q, of the induction coil I. The secondary of this induction coil is divided into two equal sections,

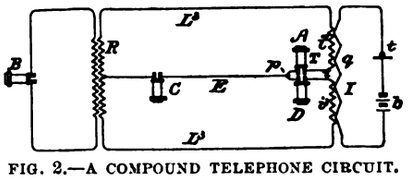

FIG. 2.—A COMPOUND TELEPHONE CIRCUIT.

$i^2$ and $i^2$, connected in series with each other through the receiving telephone, T, and the coil, D, which has an impedance equal to that of T. In the left hand side of the figure, B represents the subscriber's instrument, connected with a repeating coil, R, for transmission to the operator's set over the lines, $L^2L^2$. Connected between the point, p, and the middle of this induction coil, R, is another line, E, containing the telephone apparatus, C, which may be an order wire or instruction circuit. C can then telephone to T, but owing to the fact that its currents split and go in opposite directions through the two halves of the repeating coil, R, such conversation has no effect upon B, nor is B able to talk to C. T, however, can hear either B or C and can talk to the former. By various other arrangements of the parts different possibilities can be provided for. Patent No. 626,826.

**A Brush Holder of the Reaction Type.**—During the last two or three years various modified forms of the simple style of brush holders, known as the reaction type—originally designed and claimed in patent No. 504,901 by Mr. R. N. Baylis—have been adopted by many if not a majority of the manufacturers of direct-current dynamos and motors in this country. Among the companies adopting this type of brush holder is the Bullock Electric Manufacturing Company, three of whose engineers, Messrs. W. Cooper, W. H. Warren and C. A. Mudge, have recently obtained a patent on the combination of details of an improved form of holder of this type. A section of this improved form is shown in Fig. 3, in which A is a commutator, B a carbon brush forced against the commutator and the conducting plate of the holder by the curved arm, C, held in place by the spring, E. This spring is attached to the thumb hook, P, provided with a pin which engages in notches, p, by means of which the effective leverage of the spring and the pressure on the brush holder may be varied. This gives a remarkably simple construction and one which can be almost instantly dismantled and reassembled, as by simply pulling the hook, P, away from the arm, C, the latter

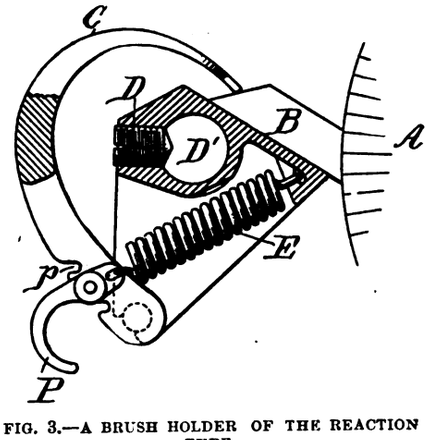

FIG. 3.—A BRUSH HOLDER OF THE REACTION TYPE.

can be taken out from the holder. Patent No. 634,804.

**A Time Element Attachment for Circuit Breakers.**—One of the inherent faults of the ordinary circuit breaker for motor protection is its instantaneous operation with any brief overload which does no particular harm to any part of the circuit. A motor will readily stand a considerable overload for a short time as in starting up, and should be made of such a size as to be occasionally overloaded so

Digitized by Google

that its average load may be at or near its point of maximum efficiency. If protected by a circuit breaker the latter will be always coming out when a brief overload exists unless adjusted to carry such an overload, in which case the motor will be burned out if the overload is continued. What is needed is a circuit breaker which will operate instantaneously in case of a violent overload or short circuit and will be sluggish or slow upon a small overload, only opening it if the condition continues. Mr. W. M. Scott has patented an attachment for this purpose to be applied to the I. T. E. circuit breakers.

The general arrangement of the parts is shown in the accompanying figure from which it may be seen that the device possesses considerable complexity. Its operation in brief is as follows: The two vertical solenoids are connected with contacts made and broken by the armature between them in such a way that the apparatus acts as a vibrator, moving the central lever up and down. A pawl, 24,

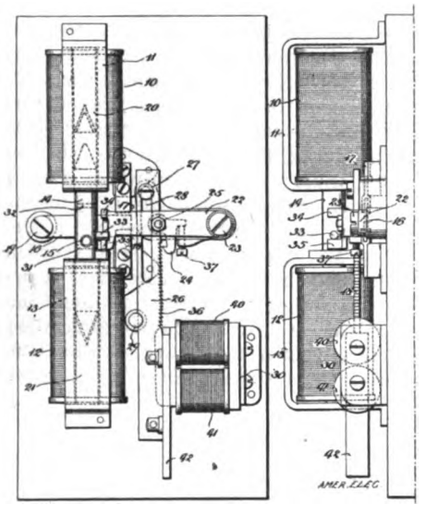

FIG. 4.—A TIME ELEMENT ATTACHMENT FOR CIRCUIT BREAKERS.

upon this lever engages the teeth of a ratchet, 26, gradually hitching the latter up, the magnet, 40, serving as a lock or catch to prevent it from falling when the pawl, 24, moves downward. When it is moved up a certain distance it closes across the mains the circuit of an auxiliary winding around the plunger of the circuit breaker proper, causing the latter to be operated in the customary way. The auxiliary apparatus shown in the figure is operated by shunt currents sent to it by an auxiliary contact on the circuit breaker proper. This auxiliary contact is worked by the regular movable plunger or core when it rises with a feeble force due to a slight overload. If this slight overload continues the ratchet is gradually worked up to the top limit, and the auxiliary coil is thrown into circuit and the breaker operated. If the slight overload ceases before the ratchet gets to the top the current is removed from the various coils shown in the figure, and the ratchet falls to its lowest position. If the overload is violent the main plunger of the circuit breaker lifts the auxiliary contact and operates the trigger directly, as usual. In spite of the complexity of the apparatus and the many other possible simpler ways of accomplishing the same purpose, the claims are very broad, the first claim covering practically the combinations of an automatic magnetic circuit breaker with an auxiliary coil closed by magnetic means in case of an overload. Patent No. 624,895.

**Electric Meter Protection.**—The shunt or potential circuits of electric meters are customarily connected on three-wire systems between one outer conductor and the neutral. If the meter is between the fuses and the lamps and the fuse is removed from the outside wire to which the meter shunt connects (let us say that this is the positive wire), then there will be voltage on the meter shunt and lights can be burned between the neutral and the negative without registering on the meter. It sometimes happens that unscrupulous consumers knowing of this will remove the fuse and thus throw the meter out of operation, getting their lights on the negative side of the system free. Mr. Eustace Oxley has patented an arrangement for overcoming this objection, which consists simply in a high-resistance shunt around the fuse. It is difficult to see how this arrangement can accomplish its purpose, since a few lamps turned on on the positive side would give a drop of practically the whole voltage in the high-resistance shunt so that the potential winding of the meter would not get any pressure even in this case. The best remedy appears to be to put the meter on the central-station side of the fuses. Patent No. 632,739.

## NOTES.

**The Underground Rapid Transit Railroad in New York City at Last Gives Promise of Actual Construction.**—The commission has advertised for proposals for constructing, equipping and operating the lines with the idea of awarding a contract within thirty days if a satisfactory bid is received before January 15, 1900.

**A Notable Hydraulic Power Plant Burned**—The power house of the Standard Electric Company at Blue Lakes City, California, was destroyed by fire on the morning of November 1st. The plant contained three 450-kw. Stanley two-phase inductor type machines feeding high-tension lines running to neighboring cities and Stockton.

**The Proposed Use of Automobile Omnibuses in New York City.**—It is stated that the New York Electric Vehicle Transportation Company, the local representative of the Electric Vehicle Syndicate, has acquired the property of the Fifth Avenue Stage Company, New York City, and will equip this famous line with electrical omnibuses as soon as they can be built. Orders are said to have been placed for a number of the vehicles, which are being constructed at the works of the Columbia and Electric Vehicle Company at Hartford.

**New High-Speed Telegraph Experiments in This Country.**—Messrs. Anton Pollak and Joseph Virag, Hungarian inventors of the high-speed system of telegraphy using a photographic receiver, recently described in these columns, have arrived in this country to conduct experiments on American telegraph lines. The system has been tested under the supervision of the Guardian Trust Company of Chicago. Speeds of about 150,000 words per hour have been obtained on short lines.

**A Tunnel for Telephone Cables.** — The Illinois Telephone & Telegraph Company, a new independent concern, is now building a tunnel in Chicago to extend from Fullerton Avenue on the North Side, south to 55th Street, with a branch westward to Western Avenue. It will be 4 feet wide and 7 feet high, lined with concrete, and will be fitted with racks for the wires and cables. The crown is about 30 feet below the street level, so as to avoid interference with sewers and pipes.

**The Sale of Power at Shawinigan Falls.**—The Shawinigan Water & Power Company, which is now developing the water power at Shawinigan Falls, Province of Quebec, is reported to have sold to the Pittsburgh Reduction Company the right to use 10,000 h. p. and to the Shawinigan Carbide Company the right to a similar amount. These companies will take the power in hydraulic form and develop it in their own generating plants. The Shawinigan Company itself is also reported to have awarded a contract to the I. P. Morris Company for a pair of turbines capable of developing 6000 h. p., or larger than those at Niagara. The Pittsburgh Reduction Company has let contracts to R. D. Wood & Company and the Westinghouse Electric & Manufacturing Company for wheels and generators, respectively, capable of developing 6000 h. p.

**An Anti-Bell Telephone Merger.**—The Telephone, Telegraph & Cable Company of America, with an authorized capital of $30,000,000, has filed articles of incorporation. The company is understood to be financed by Mr. Martin Maloney of the famous Whitney syndicate, which has already obtained extensive holdings of electric light and traction properties in the large cities. Its avowed purpose is to establish long-distance telephone lines, bringing together the various independent concerns and systems, particularly in the large cities. The hold already obtained by interests associated with the new company on conduit rights in the large cities, particularly New York, would give the company a powerful means of advancing its ends, and has given rise

Digitized by Google

to surmises and rumors that even the Bell monopoly may be outdone in its own field.

---

**A Portable Lighting Plant for Fire Department Use.**—A novel addition is soon to be made to the equipment of the New York Fire Department in the shape of a complete projecting arc-light outfit on wheels. The machine will resemble a fire engine in general appearance and will use a similar boiler, but in place of the pumping machinery the engine will drive a dynamo which will supply current for the arcs. There will be two of these, each with an 18-inch projecting lens, and these will be carried on a platform behind the driver's seat. They can be used either on the platform or removed and carried to any convenient place near by, their connection with the dynamo being kept up by means of flexible cables. The purpose of the new apparatus will be to light up dark places in the street and aid firemen in laying hose, setting ladders, etc., and also to light up the fronts of the buildings where people may be in danger.

---

**Tests of Aluminum Wire for Fire-Alarm Purposes.**—City Electrician E. B. Ellicott of Chicago has instituted practical tests of aluminum wire in Chicago for fire alarm service. The wire will be left up all winter, in a location parallel with railway tracks, where it will be subjected to fumes and smoke from locomotives. One span 225 feet long crosses the tracks; another piece is under test in another part of the city under similar conditions and alongside a new copper wire of the same size, so as to give comparative results. The comparative tests made on copper and aluminum wire before erection gave the following results:

| | Twists in 6 inches. | Breaking weight in pounds. | Elongation in 5 feet (inches). | Weight per mile in pounds. |
|---|---|---|---|---|
| No. 10 hard-drawn copper wire..... | 55 | 515 | 3 4/64 | 173 |
| No. 10 aluminum..... | 27 | 275 | 1⅛ | 51½ |

It is interesting to note that although the copper wire gave greater elongation and number of twists, the breaking weight of the aluminum wire was more than half that of the copper wire of the same size, while the actual weight of the wire was less than one-third.

---

**The Exploitation of the Marconi System in this Country.**—The Marconi Wireless Telegraph Company of America was incorporated Nov. 22d with an authorized capital of $10,000,000. The president of the new company is Mr. Isaac L. Rice of electric storage battery interests. Among the other incorporators are Messrs. Guglielmo Marconi, August Belmont and Clement A. Griscom. The company expects, among other business, to equip signal and life saving stations along the coast and manufacture wireless instruments for ships. Since the completion of the International yacht races and previous to his return to Europe, Signor Marconi made tests of the wireless system for the benefit of the U. S. Navy under the auspices of the Naval Board. The report of this board was highly favorable to the new system. Among other decisions the board made the following statements: "When two transmitters were sending at the same time all the receiving wires within range received the impulses from the transmitters. In every case under a great number of varied conditions the attempted interference was complete. Mr. Marconi, although he stated to the board before these attempts were made that he could prevent interference, never explained how nor made any attempt to demonstrate what could be done. Between large ships (heights of masts 130 and 140 feet) and a torpedo boat (height of mast 45 feet), across open water, signals can be read up to 7 miles on the torpedo boat and 85 miles on the ship. When ships are close together (less than 400 yards), adjustments, easily made, of the instruments are necessary. The rapidity is not greater than 12 words per minute with skilled operators."

---

**Electric Motor Auxiliaries for the Navy.**—In his last annual report Chief Engineer Melville, of the U. S. Naval Department, explains the hitherto announced decision not to use electric motors generally for auxiliaries in ships now under way or planned. After outlining the well-known advantages, such as the absence of heat, condensation and danger from shot and shell in electric wires, as compared with steam pipes, the report continues as follows: "Against these, however, are to be put the much greater weight of the necessary electric outfit, the greater delicacy of the type of electric motors ordinarily used, the lack of ready adaptability to the various conditions of service, a general denial of the claims for economy as ordinarily presented, and the increase in the amount of space required below the protective deck for the installation of the necessary dynamo rooms, this space being necessarily taken from coal bunkers. . . . On the battleship 'Alabama' the space required for electric motors, where used, is approximately the same as that required for steam engines to do the same work. The space required for the wiring, etc., is less than that necessary for steam piping, had that been used. The space required for the generating sets is 10,140 cu. ft. The capacity of these generating sets is 256 kw. total. If all the auxiliary machinery on board this ship were operated by electricity, and if the space required for the electric generators were increased in the ratio of the increase of necessary capacity in the generating room, the space that would be required in the generating rooms would be 50,700 cu. ft. for a capacity of 1,280 kw. Consequent upon the extension of the use of electricity would be an increase in the total weight of the machinery equal to from 150 to 250 tons as a minimum. This loss in weight is as much as the gain following the use of water-tube boilers. The increased space occupied by the larger generating rooms would accommodate 900 tons of coal, or 3,600 h. p. could be added to the power of the propelling engines, giving the ship in the first instance 45 per cent. greater coal endurance, or in the second instance 1.5 knots increase in speed."

---

**High-Speed Service on Private Rights of Way in Buffalo.**—The International Traction Company has recently put in service a new route for the Buffalo & Lockport line. On account of the length of this line, high speed and a private right of way are almost imperative. Between Tonawanda and Lockport the cars always have run on the Erie railroad tracks, but heretofore they have followed the street route of the Niagara Falls line between Tonawanda and Buffalo. The new section consists of a track about six miles long from Tonawanda in to Buffalo city line, where it turns into Main Street near Cold Spring, and thence runs down town. The new private right of way has allowed a considerable reduction of the schedule time, which is now 70 minutes between the downtown section of Buffalo and Lockport, the time on the New York Central road being from 50 to 55 minutes. Of this 70 minutes 30 minutes is spent on the streets of Buffalo, the average speed on the private right of way being about 45 miles per hour between stops, with mixmum speeds running up to nearly 60 miles per hour. The new section of the road is single track, laid with 85-pound American Society standard rail, the whole line being operated by a regular train dispatching system exactly like that of the steam roads. The passenger cars run every 30 minutes throughout nearly the whole day. The new section embodies a slight departure from previous overhead construction designed by Mr. C. K. Marshall. The overhead wire is carried by bracket construction, but instead of suspending the trolley wire immediately from the brackets, a 7/16-inch stranded steel cable is strung the whole length of the line and the trolley wire is hung from this cable by means of ordinary straight-line hangers offset on the cable a considerable distance from the brackets. This gives flexible suspension and in addition prevents any break of the trolley wire from twisting out of shape several brackets. The International Traction Company has also directed the General Electric Company to gear up one of its freight locomotives for experimental purposes, to determine its applicability to passenger train service. The locomotive will be geared to give a maximum speed of 70 miles per hour, and if this speed can be attained with a load of 150 tons, electric locomotives will be adopted on the Erie tracks between Buffalo and Niagara Falls to haul the regular Wabash and other passenger trains.

### High-Voltage Three-Wire Systems.

There will be found in this issue of the American Electrician descriptions of two central stations operating multi-wire systems of distribution with double the voltage customary on Edison systems. One is a large metropolitan plant supplying an extensive underground district, while the other is in a small place and designed for scattered loads. While three-wire direct-current systems with 400 to 500 volts between the positive and negative conductors have become almost standard practice in England, they are as yet rare in this country and a word or two as to their advantages and disadvantages may be of interest.

The chief disadvantage is of course the poor economy of the high-voltage incandescent lamp. In the present state of the art of lamp making a 16-c.p. 220-volt lamp requires from 60 to 65 watts, while a 16-c.p. 110 to 115-volt lamp of corresponding life, deterioration, etc., requires only 50 watts. To be sure, if current is sold on a kilowatt-hour basis the consumer stands the extra cost, but this handicaps the station—once it is known—competing with other systems or with gas. On this account power for lighting at least should be sold on high-voltage systems at a rate about 20 per cent lower than is quoted by low-voltage stations. Another disadvantage that might carry considerable weight at first is the increased risk due to the high pressures, but as pointed out in the article on the Imperial plant of St. Louis, the modern systems of interior wiring with approved fittings are safer under high voltages than the average work of a few years ago is under ordinary voltages.

The great advantage of the high-voltage is of course the reduced cost of copper and the consequent increased available radius of supply. For a given distribution the necessary amount of copper is of course reduced by doubling the voltage 75 per cent, although the cost of the insulation and the installation of the feeders and mains is not reduced in this proportion and the cost of pole lines or conduits may not be reduced at all. As to increased radius of supply, Mr. Humphrey states in the article on the Imperial plant that "the area which can be supplied from one central station at the same percentage of loss is increased 16 times." This means that the radius of supply is multiplied by four by the adoption of the higher voltage. While this is theoretically the case with the same cross section of feeders and with the same load, it is not commercially the case figured on the basis of the same cost of the distribution system per kilowatt distributed. If the same amount of copper is used for the same percentage drop the radius of supply is only twice as great with the high-voltage system as with the low, and the area of supply is increased four times instead of 16 times. Even then the cost of the distributing system is considerably increased as the copper is but a small fraction of the total cost, and the cost of insulation, lead, conduits, etc., is more a factor of the length than the cross-section of the feeders.

With the constant tendency toward the concentration of the generating system into one central power house the high-voltage three-wire system becomes the only means of distributing power over a city of moderate dimensions by means of direct-current without resorting to substations and a rotary-converter system. A great practical advantage of the high-voltage system in many cases is the possibility of bringing all motors previously operated on 500-volt power circuits on to the lighting service, thus considerably simplifying both the generating machinery and the distribution system.

### Balancing Three-Wire Systems.

It has always been customary in this country to supply three-wire systems from separate generators on the positive and negative sides, each machine delivering half the voltage of the system and being connected between the neutral and one of the outer bus bars. While this practice is commendable and necessary in small installations, it becomes a source of unnecessary multiplication of machines in stations running many generators and a source of no little loss when the generators become of large size. Where the number of generating units becomes large the actual number of dynamos can be cut in two by substituting for the positive and negative machines of each generating unit one dynamo of double the voltage connected between the outer conductors and maintaining the proper mid-potential of the neutral by some other means.

The means most commonly adopted for this purpose in England where full-voltage machines are more common, is the use of two shunt-wound motors mechanically coupled together with their armatures electrically connected in series with each other across the outer mains. If the load upon one side of the system becomes greater than that upon the other, the motor upon the lightly loaded side absorbs electrical power, giving it mechanically to the other machine coupled to it, which acts as a generator delivering the power to the heavily loaded side. In extensive installations where the sizes of the generators become large, 1000 kw. or more, the losses through the double commuta-

Digitized by Google

tion, the double equipment of leads from the switchboards and the switches, become quite serious. The use of single machines generating the full voltage of the system materially reduces these losses as well as the first cost of the whole equipment. A large three-wire system is always so nearly balanced that a very small pair of machines, compared with the whole generating equipment, will serve to maintain the balance.

---

**Static.**

Whatever limitations of voltage may or may not be found in long-distance transmission on aerial lines, a serious check has been found wherever the transmission is compelled to be as a whole or in part via underground cables. This limitation is due to what is commonly called "static." But little seems to be known concerning the cause or origin of this phenomenon, but its effects are universally found wherever an underground cable forms part of a high-tension scheme. It manifests itself as a charge tending to jump to ground with a voltage apparently much higher than that supposed to be in use on the system. If no less resistant path of discharge is provided this static will invariably rise to such a pressure that it will puncture the cable insulation. If a path is provided—a common form consisting of an air gap in series with a high resistance—static will occasionally jump this gap, which can be made much wider than any gap which the nominal voltage of the system would jump. If paths of this kind are not provided the static has an annoying way of creeping and sparking over considerable distances at cable heads and similar locations where it can follow the surface of the insulation from the conductors to ground, gradually eating or burning away the insulation until a complete breakdown follows.

---

Exactly what this static is due to does not seem to have been as yet clearly determined, or at least does not seem to be understood by many who are troubled by it. Every high-tension circuit consists of a number of lines, transformer windings and in some cases machine windings all insulated by many megohms resistance from the earth. For some reason this highly insulated system seem to become, when in operation, electrified until sparks jump to ground at the weakest point, no matter how strong the insulation may be. The static may be due to effects of capacity and self-induction piling up charges and high potentials at certain points in the cables; it may be due to selective-leakage, a positive charge passing through the dielectric to ground more easily than a negative, or it may be due to some entirely different cause, but whatever its source, it seems to limit the pressure which can be commercially applied to alternating-current underground systems in the present state of the art to about 10,000 to 12,000 volts. Higher voltages cause frequent break-downs, no matter how thick the insulation may be (not due directly to the electrostatic stresses, but due to the indirect effects of static), so that engineers rarely attempt them.

---

What would perhaps prove a simple cure is the grounding of one leg of the system, or, better, of a common neutral point, an arrangement sometimes used abroad. With a direct electrical connection to ground it is difficult to see how the potential of any leg of the system could differ from that of ground by any more than the voltage set up by the generating apparatus. This cure is, however, considered objectionable in this country, as with it the accidental grounding of any conductor would cause a short circuit and consequent interruption of supply. On the extensive high-tension systems now in use in this country grounds are frequent, but in each case are easily removed before another ground occurs on another leg of the system, so that they cause no interruption of service. Another possible remedy that would not be open to this objection is the use of induction or choke coils with an ample cross section of copper connected between the high-tension conductors and ground. These would serve to give an electrical connection which would discharge any abnormally high electrostatic pressures, but in case of a ground on any leg of the system would not act as short circuits.

---

**Guarantees.**

The custom of requiring and giving most elaborate and rigid guarantees of the performance of steam and electrical machinery appears to be on the increase. Engine makers bidding for recent contracts must guarantee not only the steam consumption over a considerable range of load, regulation under combined changes of load and steam pressure with or without a vacuum, a large maximum overload capacity, but oftentimes a slight maximum variation from true uniformity of rotation, or some similar difficult requirement. A dynamo maker must guarantee no more than a certain rise in temperature in various parts of the machine under a given load, the ability to carry a very heavy overload without sparking, insulation resistance, regulation, efficiencies at various loads, and oftentimes peculiarly difficult specifications of the purchasing engineer.

---

A notable case of stringent guarantees is that of the Imperial plant in St. Louis, some of which guarantees are mentioned in the paper by Mr. Humphrey on other pages of this issue. In addition to the individual guarantees on the separate machines the whole station in this case was covered by one blanket guarantee of the contractor to give a certain efficiency as a whole, a definite cost of coal per kilowatt hour delivered to outside circuits from the switchboard being specified.

---

While this practice of requiring guarantees of a highly perfect performance undoubtedly improves the quality of machinery supplied, it often does so at great cost to the consumer. The penalty in the case of failure of all small contracts is the rejection of the apparatus, which compels the manufacturing companies to allow a sufficient margin in the contract price to cover the risk. A dynamo which would be otherwise a highly perfect machine might not be able to carry a 50 per cent overload without slight adjustment of the brushes and without sparking. This may cause the rejection of the machine, although in other qualities, such as heating, etc., it may be quite superior. Indeed, it is often the case that the machine rejected is on the whole better than the machine given in its place, particularly if the quality in which the first machine was deficient requires a sacrifice of some other good feature, as is often the case. Frequently no real adequate test is made as to whether the machine does or does not comply with the guaranteed requirements. This is a particularly unfortunate condition, as it allows unscrupulous bidders to put in poor machinery and run the risk of detection. This is particularly likely to happen in cases where it is difficult to make accurate tests, as for instance, in the case of the efficiency of direct-coupled machines. Perhaps a most conspicuous example of rigid specifications are those of the United States Government. On account of them the Government pays much more for its supplies and equipment than does any private consumer, getting better apparatus, but probably not enough better to warrant the additional outlay.

## COMMUTATOR DESIGN AND CONSTRUCTION.

BY ALTON D. ADAMS.

It is perhaps fair to say that direct-current dynamos and motors depend more for satisfactory operation on properly designed and constructed commutators than on any other one feature. Bad proportions in other parts of the dynamos may lower the efficiency slightly or unduly raise the temperature of some part, and yet the defect be hardly noticed in the practical operation of the machine, but if the commutator bars are of poor material, loose or of insufficient surface to transmit the required current, the heating, sparking and flashing are quite apt to be such as to interfere with or prohibit the operation of the machine. The commutator being that part of the dynamo subject to the most rapid wear and the only machined portion likely to require renewal, aside from the bearing bushings, it is important that electrical repair companies and machine shops in general should understand the special methods necessary in its construction and some of the main problems of its design. A few years since, commutators were frequently made with materials that have sinced proved unsuitable and were almost always proportioned for copper or other metallic brushes, so that when these older commutators came to the repair shop, as they are constantly doing, there is usually opportunity for improved constructions, especially if it is desired to replace the copper with carbon brushes. There are many points in the design of commutators which are necessarily connected with the electric and magnetic characteristics of the electric machines for which they are intended, and these points it is not the purpose to touch upon here, the object at this time being simply to point out the relation of ampere capacity to segment dimensions, certain considerations connected with insulation, and particularly features and methods of construction conducive to mechanical security in commutators.

It may be said, with little fear of contradiction, that by far the majority of commutator troubles are due to mechanical rather than electrical defects, and as a matter of design it has proven much simpler to procure suitable electrical proportions than to insure mechanical solidity.

### SEGMENTS.

Starting with the question of ampere capacity, it should be noted at once that the number of segments in a commutator is fixed by electric and magnetic considerations and has no direct bearing on current capacity. The amperes which a given commutator will properly transmit depend on the surface area of one segment, the kind of brush used, the number of segments that may be in contact with one brush and the material of which segments are made.

The number of segments on which a carbon brush may safely rest at any one time varies somewhat with the design of the particular machine, but in most direct-current dynamos and motors of 500 volts, or less, pressure, the width of the carbon brush may safely equal that of two segments, so that the brush may touch three segments at the same time.

A brush contact much wider than two segments is very apt to cause sparking, and in most cases a narrower brush unnecessarily reduces ampere capacity of contact. Some years ago, when metallic brushes were in general use, brush contact areas often had a current density of 100 to 125 amperes per square inch; later, fifty amperes per square inch was considered good practice for carbon brush contacts, and this density has gradually been reduced until now thirty amperes per square inch may be taken as a fair maximum. These densities for brush contacts are based on the use of pure drawn or forged copper for segments, on which good practice has now mainly settled, and if castings of copper alloys are used for segments the density at brush contacts should be diminished.

The inducements to use cast segments are now small, as drawn copper can be had that is truer to gage than castings, at a less price, and is certain to be free from blowholes. As the area of brush surface for a single segment depends on both length and width, the required contact area is sometimes secured by rather long, narrow segments, and at others with segments comparatively wide and short. The tendency in new work, however, is toward rather short, wide segments, resulting in commutators of quite large diameters as to their length, which are more easily made mechanically solid, and save also in length of shaft and base.

The long, narrow segment, with the resulting commutator of small diameter as to length, was more in favor on old machines, and it will often be found when one of these commutators is to be replaced that by the use of wider segments ample contact surface for carbon brushes can be secured in the original commutator length, while the increased diameter permits the use of improved methods of construction. In addition to the length of segments necessary for brush contacts it is desirable to allow from one-half to one or more inches in their length for the end motion of the commutator, and for clearance at each end. There must also be room for the proper attachment of armature conductors.

Concerning the maximum width of segments it may be said that carbon brush contacts, three-fourths and even seven-eighths inch wide, are being used, and it is doubtful whether these limits should be much exceeded in small machines, since difficulties of secure contact increase with the width of arc.

As commonly constructed, current enters and leaves a commutator once for each pair of poles, so that in a bipolar machine two segments must deliver the entire current, in a four-pole machine four segments, and so on, allowing for brushes wide enough to cover two segments.

In some multipolar machines the armature windings are so connected that but two sets of brushes are used, and for these cases each set must conduct the entire current, a construction which usually results in a commutator large compared with the machine to which it is connected.

Every commutator may be broadly divided into three parts, the segments which conduct the current, the insulation which separates the segments from each other, and from the clamps, and the shell or clamping parts which hold the numerous pieces together.

The segments, with their intermediate insulation, must form a true, hollow cylinder, the so-called segments being really circular sectors and the insulating sheets small parallelograms except as to the slight curve of their outside edges. The number of segments or sectors of which a commutator is made up fixes the angle between the sides of each segment, without regard to the insulating mica strips between them, and the width of the segment at its outside edge being determined for the desired ampere capacity of brush contacts and its radial depth fixed by considerations of wear and mechanical stiffness, the thickness at the inside edge may be readily calculated.

It is quite important that the sides of the segments have, as to each other, very nearly the correct angle, else the segments will touch the mica strips at only the inside or outside edges and it will be found impossible to hold them rigidly together. It is a good rule to require that the thickness of segments shall not vary from the standard dimensions for their thick and thin edges by more than one-thousandth of an inch in either direction, so that the thickness of segments shall not vary more than two-thousandths of an inch from each other. This degree of accuracy can readily be attained in either forged or drawn bars.

### INSULATION.

Nowhere else in electrical machines are the requirements as to insulating materials so exacting as in commutators. Among these are great strength to resist compression, high insulating properties, impunity to high temperatures, small power to absorb moisture and smooth wearing qualities; also capacity for accurate division. A variety of substances, as fibre, asbestos, wood and mica, have been used for commutator insulation in the past, but the mica has alone stood the test of time for general use in this capacity.

The mica used must be free from metallic impurities, and that used between the segments should be as soft as possible, the so-called amber mica being much used in this position, so as to wear at about the same rate as the segments.

The thickness of mica between the segments varies in practice from about .02 to as much as .06 inch, these differences being due in part to the design and pressures of various machines. For dynamos and motors of not over 500 volts pressure,

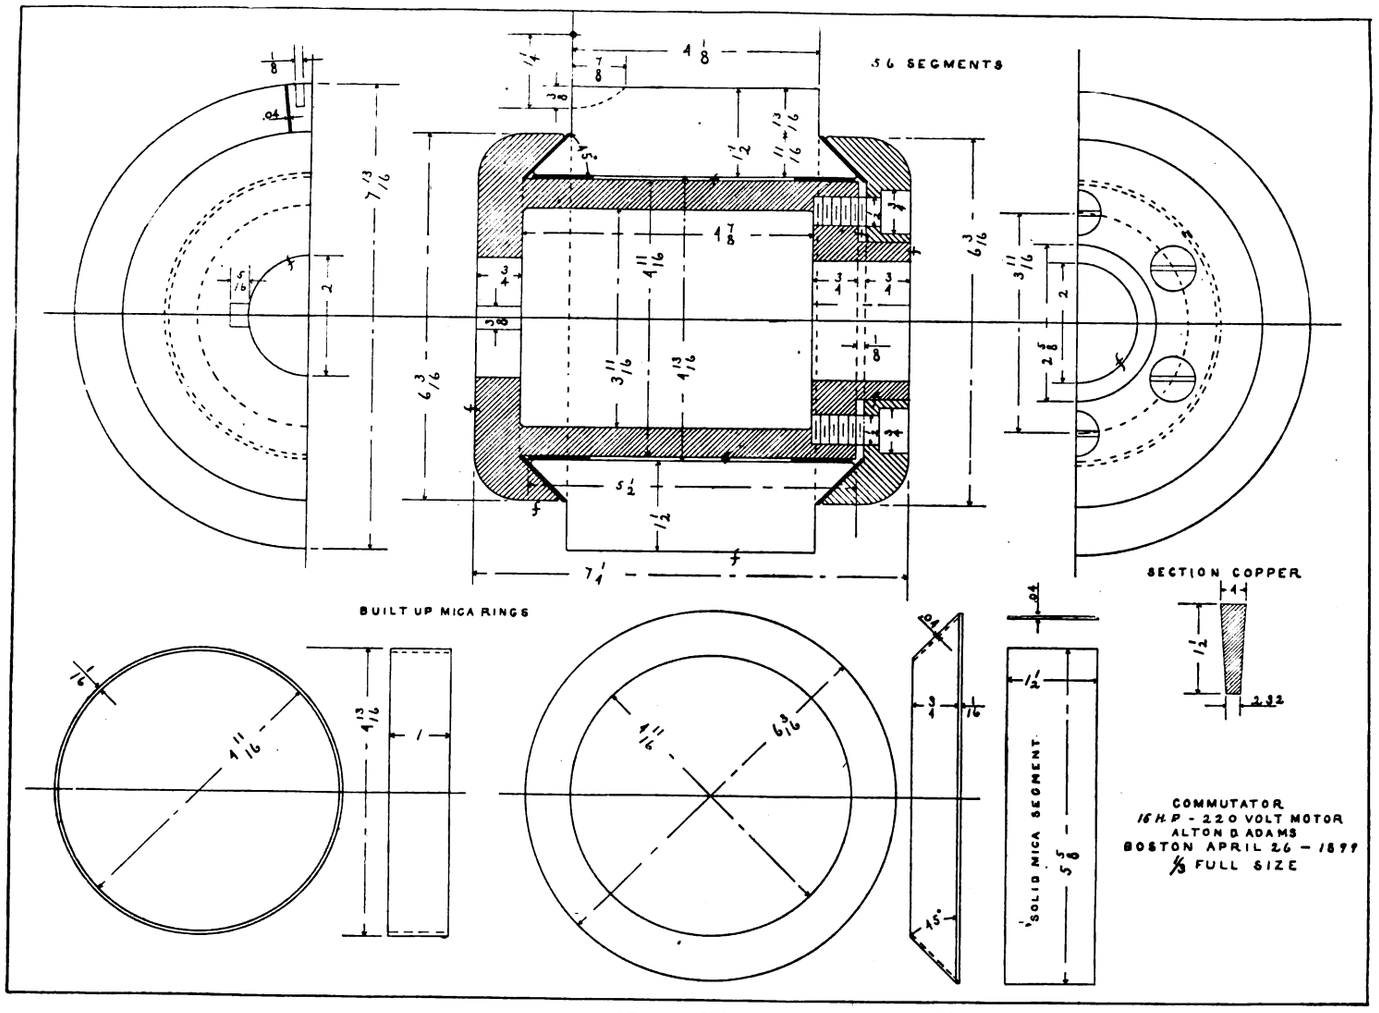
Digitized by Google

whose proportions do not require some special dimensions for the mica between segments, a thickness of about .04 inch will in many cases be found satisfactory.

If the mica between commutator segments is too thick it gives trouble by extending beyond them, after a little wear, thus tending to lift brushes from contact with the segments and form an arc; while if too thin the carbon particles worn from the brush are apt to bridge across the mica and cause flashing. To insure that mica between segments will not flake out and will wear in the best manner it is well to divide it into strips .002 or .003 inch thick, and stick these together with shellac, using shellac also on the side of each segment when put together. The rings which insulate the segments from the commutator sleeve and clamping parts should also be of built-up mica, and usually from .04 to .06 inch thick.

COMMUTATOR SLEEVES.

The purpose of the sleeve is to hold the commutator segments rigidly in position, and unless it does so the machine becomes practically useless through excessive sparking and heating at the brushes. The design should be such as not only to hold the segments at a fixed diameter but also to maintain enough side pressure between them to securely clamp the mica. This side pressure, however, cannot be relied on to resist radial motion, which can only be prevented by a solid contact with mica rings both above and below.



In order to secure the clamping action of the sleeve on the segments it is common to use either a single or a double taper on the clamping parts; with the single taper segments must bed solidly on to one straight surface, while with the double taper both holding surfaces come on at an angle.

Where large numbers of commutators are being made and special tools and jigs can be had, there is a slight advantage in the double taper construction, but in the manufacture of a few machines without much outlay for special equipment, the single taper form of clamp is to be preferred.

The parts of commutator segments which extend between the clamps may be either at each end or underneath, so that the segments extend out over the clamps. The first method makes a little longer commutator, but is quite easy to make, while the second is harder to follow with ordinary tools. Formerly it was the custom to hold the clamps in position by a screw collar on one end of the sleeve, but the later construction, which is also better and cheaper, employs several cap screws or bolts for the purpose. It is impractical to bring the segments to a proper degree of tightness with the clamps of the commutator sleeve, but this must be done with suitable rings or presses outside, and the commutator clamps subsequently employed to hold the compression thus gained. Cast-iron forgings and steel castings have been used for commutator sleeves and their clamps, but cast-iron is perhaps the most common and is suitable for the purpose if made sufficiently heavy. The very general use of carbon brushes now requires a more substantial commutator construction than was common when the metallic brush was in general use, as it is impractical to use carbon brushes on commutators having high and low bars, since the brushes, in passing over these bars, are lifted from their contacts, breaking the current and causing destructive sparking and heating.

The metallic brush, when lifted at one point, usually retains contact at others because of its yielding nature, but the carbon brush may be so lifted as to touch at a bare point.

Troubles with high and low commutator bars and carbon brushes usually grow

DESIGN FOR THE COMMUTATOR OF A 15-H. P., 220-VOLT MOTOR. SCALE, ⅛ ACTUAL SIZE.

Digitized by Google

worse very rapidly, as the heat that results from sparking causes excessive expansion of the bars, this tends to loosen them more and the actions become cumulative.

After a commutator is completed it may be tested for tightness by holding a piece of hard fibre on each segment and striking the fibre a fair tap with a light hammer, then feeling over the joints between segments and mica to see if they have developed high and low bars.

### 60-AMPERE 220-VOLT COMMUTATORS.

To illustrate some of the features of design and construction pointed out, take the case of a commutator for a 60-ampere 220-volt dynamo or motor of the bipolar type.

As this commutator is to deliver 60 amperes, the actual area of brush contacts for each set should be equal to $60 \div 30 =$ 2 square inches, on the basis of 30 amperes per square inch of contact. Allowing the width of brush contact to be .8 inch, the length of contact surface becomes $2 \div 8 =$ 2.5 inches, and adding 1⅝ inches for armature connections, end play of commutator and clearance, makes the total length of the top of segment 4⅛ inches.

It having been decided to let each brush contact cover about two segments, the thick edge of bars for this commutator, before they are turned to circular shape, is taken at .4 inch. To secure great mechanical solidity the radial depth of bars is taken at 1.5 inches, and it is now necessary to calculate the thickness of the bar at the inside or thin edge, for which the number of segments in the commutator must be known.

It having been decided for reasons connected with magnetic and electric features of design to put 56 segments or bars into this commutator, the angular space occupied by each bar, or the angle between its sides, must be equal to 360 degrees divided by 56, or 6 degrees and 26 minutes, neglecting the mica, which does not affect the angle of the segments.

Now it is evident that the tangent of one-half the angle of the bar is equal to one-half the difference between the thick and thin edges divided by the depth of the bar, that is $\tan [(6° 26') \div 2] = \frac{X}{1.5}$, when X is taken as one-half the difference between the thick and thin edges. Solving above equation for the value of X gives .084, so that the dimension for the thin edge of the bar is $.4 - (.084)\ 2 =$ .232 inches. This bar is to be cut from drawn commutator stock, and as the armature leads are small they will be soldered directly into slots cut in each bar by a milling machine. Insulating strips between segments and the rings are of built-up mica of the dimensions shown on the previous page, which experience has proven satisfactory in similar cases.

In case the mica rings are found too thin at any point when the commutator is put together, the necessary amount of mica is added.

## AMERICAN TELEPHONE PRACTICE.

### TESTING.*

BY KEMPSTER B. MILLER

In a large class of tests—that is, those requiring quantitative measurements—there are three distinct subdivisions, which are as follows: Tests for resistance or conductivity, tests for capacity and tests for insulation. Tests for the location of faults in lines always depend on the application of one or more of these.

There are three principal methods of making resistance tests: First, by the use of a Wheatstone bridge, which is accurate for all resistances except those very large or those very small. Second, the fall of potential method, which is of value in measuring very small resistances, as of a large conductor, such as a trolley-wire or heavy feeder. This method has little use, therefore, in telephone work where all conductors are comparatively small. Third, by the use of a sensitive galvanometer in series with a battery. This method is the most accurate for the determination of extremely high resistances and is, therefore, of great use in measurements of insulation resistance.

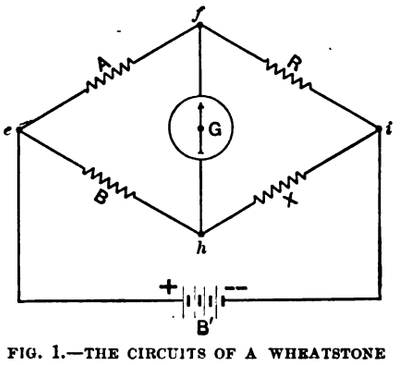


FIG. 1.—THE CIRCUITS OF A WHEATSTONE BRIDGE.

For general resistance measurements the Wheatstone bridge is the most suitable, being very accurate and exceedingly simple in manipulation. In order to appreciate the possibilities of this instrument its underlying principles should be understood. In Fig. 1, A, B, R and X represent resistances. G is a galvanometer or instrument for detecting the flow of current through it. The four resistances are connected together as shown, the galvanometer being connected in the "bridge" between the juncture of A and R and B and X. A battery, B', is connected between the junctures of A and B and of R and X. Each resistance, A, B, R or X, forms what is termed an arm of the bridge.

The two fundamental laws upon which the action of the bridge is based may be stated as follows:

1. No current will flow between points of equal potential; and

2. The drop in potential along the various parts of a conductor is proportional respectively to the resistances of those parts.

* From a book to be published by the American Electrician Company.

Referring again to the diagram, it is evident that a current from the battery flows to the point, e, where it divides, part flowing through A R and part through B X, after which they unite and pass to the negative pole of the battery. But what of the galvanometer? Evidently by Rule 1 the only time at which no current will pass through it will be at the time when the points, f and h, are at the same potential. By Rule 2 these points will be at the same potential only when A bears the same relation to R as B does to X.

That is

$$A : R :: B : X, \text{ or, by alteration, } \frac{A}{B} = \frac{R}{X}.$$

A little algebra will render the above evident if not so already.

Call ei the drop of potential between the points e and i, ef that between e and f, and eh that between e and h.

Then

$$ef : ei :: A : A + R \text{ by Rule 2.}$$

Therefore,

$$ef = \frac{A}{A + R} ei.$$

Similarly

$$eh = \frac{B}{B + X} ei.$$

For a condition of equal potentials at f and h so that no current will flow through the galvanometer, e f must = e h.

Then

$$\frac{A}{A + R} ei = \frac{B}{B + X} ei$$

$$AB + AX = AB + BR.$$

$AX = BR$, dividing by BX, we have $\frac{A}{B} = \frac{R}{X}$, which is the equation of the ratios between the resistances of the arms of the bridge, to insure no flow of current through the galvanometer.

The resistance to be measured forms the arm X of the bridge, and in order to determine its value the resistances in the various arms are adjusted till no current flows through the galvanometer. Then the equation just derived holds good and may be solved for X,

$$\text{thus } X = \frac{B}{A} R.$$

The arms A and B are best termed the "ratio arms" of the bridge and arm R the rheostat arm.

In commercial forms of the Wheatstone bridge, A and B are usually so arranged that each may be given the values, 10, 100, and 1000 ohms, and in some cases 1 ohm and 10,000 ohms also. The ratio arms, A and B, may therefore be adjusted to bear any convenient ratio to each other from $\frac{10}{1000}$ to $\frac{1000}{10}$, or, in some instances, from $\frac{1}{10,000}$ to $\frac{10,000}{1}$. The rheostat arm is in reality a rheostat capable of being adjusted to any value from 1 to about 11,000 ohms.

In some bridges, sealed batteries are furnished with and form a part of the instrument. In those having no battery,

Digitized by Google

suitable binding posts are provided, usually marked BB, between which the batteries may be connected. Other binding posts, usually marked XX, are furnished for connecting the terminals of the unknown resistance to be measured.

Two keys are usually furnished, one in the battery circuit and the other in the galvanometer circuit. Each keeps its circuit normally open.

The operation of the bridge is very simple. First some ratio between the arms A and B is determined upon. The battery is then connected between the proper binding posts, and likewise the resistance to be measured is connected between its binding posts.

The battery key is first depressed and then the galvanometer key. A deflection of the galvanometer needle will take place which by its direction will after a few trials show whether the resistance in the rheostat arm is too great or too small. The rheostat is adjusted accordingly until the galvanometer needle shows no deflection upon the operation of the keys. We then know that our equation

$$\frac{A}{B} = \frac{R}{X} \text{ holds good,}$$

and consequently

$$X = \frac{B}{A} \times R.$$

That is, the unknown resistance is equal to the ratio between B and A multiplied by the resistance in the adjustable arm.

Considerable judgment may be exercised in the choosing of the appropriate ratio in the ratio arm to obtain the greatest accuracy. Obviously if a very high resistance is to be measured the ratio should be large, and vice versa.

In bridges having resistances of 10, 100 and 1000 ohms in the ratio arms, the following values in arms A and B will give the best results:

| Resistance to be measured. | A arm. | B arm. |
|---|---|---|
| Under 100 ohms | 1000 | 10 |
| 100 to 1000 ohms | 1000 | 100 |
| 1000 to 10,000 ohms | 1000 | 1000 |
| 10,000 to 100,000 ohms | 100 | 1000 |
| 100,000 to 1,000,000 ohms | 10 | 1000 |

As to the accuracy of measurements attainable by the use of the Wheatstone bridge, the following table represents the claim of one reliable manufacturer:

| | | | | | |
|---|---|---|---|---|---|
| .01 | of an | ohm | to an | accuracy of | 1 p.c. |
| .1 | " | " | " | " | ½ " |
| 1 | ohm | " | " | " | ⅛ " |
| 10 | ohms | " | " | " | 1/15 " |
| 100 | " | " | " | " | ⅛ " |
| 1000 | " | " | " | " | ⅛ " |
| 10,000 | " | " | " | " | 1/15 " |
| 100,000 | " | " | " | " | ¼ " |
| 1,000,000 | " | " | " | " | 5 " |

If using the 110-volt lighting circuit as battery power 1 megohm may be measured accurate to ½ per cent.

There is no doubt but that with a well-made bridge with a sensitive galvanometer, these results may be equaled if not surpassed. Great care must be taken in using a voltage as high as 110, as there is danger of burning out the coils. Such high voltage should be used only in measuring very high resistances, and the ratio arms should be adjusted to give as high a multiplying ratio as possible.

It is frequently found that a current that it is desired to measure is so large that it sends the spot of light completely off the scale, thus rendering the measurement of the deflection impossible. In order to increase the range of the galvanometer so as to make it available for measuring both large and small currents, certain resistances called shunts may be placed in parallel with the galvanometer coil as in Fig. 2. The resistance of the shunt being known, it is easy to calculate the amounts of the currents that pass through the galvanometer coil and the shunt.

Calling $R_g$ the resistance of the galvanometer, $R_s$ that of the shunt, $C_g$ the current through the galvanometer, $C_s$ that

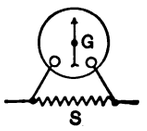

FIG. 2.—THE CONNECTION OF A GALVANOMETER AND SHUNT.

through the shunt, and C the total current through both, then

$$C = C_g + C_s.$$

Also when E is the difference of potential betwen the common terminals of the galvanometers and shunt,

$$C_g = \frac{E}{R_g} \text{ and } C_s = \frac{E}{R_s}.$$

$$E = C_g R_g = C_s R_s. \text{ Hence } C_s = \frac{C_g R_g}{R_s}.$$

Substituting this value of $C_s$, in the first equation, we have

$$C = C_g + \frac{C_g R_g}{R_s} = C_g \left(1 + \frac{R_g}{R_s}\right) = \frac{R_s + R_g}{R_s}.$$

This quantity $\frac{R_s + R_g}{R_s}$ is called the multiplying power of the shunt, because it represents the number by which the

FIG. 3.—A COMMERCIAL FORM OF SHUNT BOX

current through the galvanometer must be multiplied, in order to give the value of the current being measured.

Shunt boxes are usually provided for a given galvanometer with a number of coils specially arranged to give such convenient values of the multiplying powers, as 10, 100 and 1000. For this purpose the various coils of the shunt box have resistances of 1/9, 1/99 and 1/999 of the resistance of the galvanometer.

To better show this rule, assume that a multiplying power of 1000 is desired, then

$$1000 = \frac{R_s + R_g}{R_s}$$

$$1000\,R_s - R_s = R_g$$

$$R_s = \frac{R_g}{1000 - 1} = \frac{R_g}{999}.$$

A commercial form of shunt box is shown in Fig. 3, the various multiplying values of the shunt being obtained by plugging the block corresponding to the multiplying power desired.

For moderate deflections, the current traversing the coils of a reflecting galvanometer may, without sensible error, be taken as proportional to the deflection of the spot of light on the scale, or to the deflection read through the telescope. The current is, of course, inversely proportional to the total resistance of the circuit, and from this it follows that the deflections are inversely proportional to the resistance. This fact enables the galvanometer to be used for measuring unknown resistances by comparing a deflection obtained when a given e. m. f. acts through a known resistance with that obtained when the same e. m. f. acts through an unknown resistance.

The general method of measuring resistances by the use of a galvanometer is to note the deflection obtained with a given battery and a known resistance in the circuit, and from this to compute what is called the working constant. This working constant may be defined as the number of scale divisions deflection that would be obtained by causing the current from the given battery to pass through the galvanometer and a resistance of one megohm. Of course such a deflection as this can exist in our imagination only, but it serves, nevertheless, as a convenient standard upon which to base our calculations. Having obtained the working constant, a reading is taken of the deflection produced by passing the battery current through the galvanometer in series with the unknown resistance. As the deflections are inversely proportional to the resistances, the unknown resistance is then readily computed.

If measurements of comparatively low resistance are to be made, then the resistance of the battery and of the galvanometer must be taken into consideration as well as that of the resistance placed in circuit with them, but as the measurements here considered will be those of very high resistances only, the resistance of the battery and of the galvanometer may be neglected. For the purpose of taking the constant connections are made as shown in Fig. 4, where B is the battery, G the galvanometer, S the shunt and R the known resistance. Usually the value of R is 1/10 of a megohm, or 100,000 ohms. With the 1/999 shunt a certain deflection will be obtained when the circuit is closed. Obviously, if the shunt were not present the deflection would be 1000 times as great, because only 1/1000 of the current passes through the galvanometer. Therefore the total deflection, if it could be measured, that would be produced

Digitized by Google

through the galvanometer and the 100,000 ohms resistance, would be the deflection noted multiplied by 1000. If, now, the resistance, R, had a value of 1 megohm instead of 1/10 megohm, the deflection would have been only 1/10 as great as

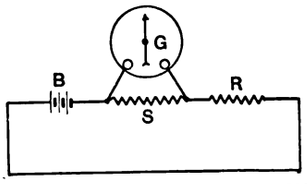

FIG. 4.—CONNECTIONS FOR CALIBRATION OF SHUNTS.

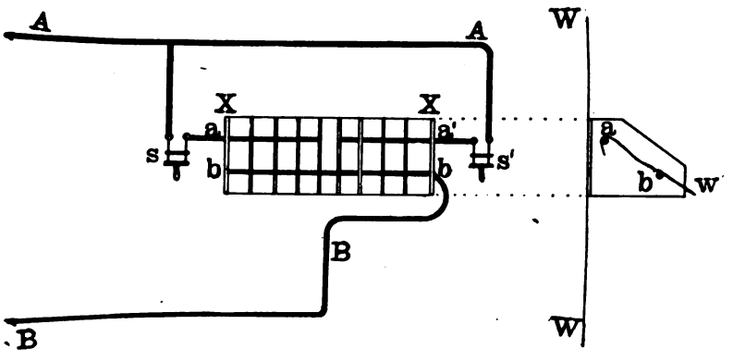
this. Therefore to find the number of scale divisions of deflection which the galvanometer alone would give with 1 megohm in circuit, we multiply the deflection noted by 1000 and by 1/10.

In general we may say: To find the working constant, multiply the deflection obtained by the multiplying power of the shunt, and by the value of the known resistance in megohms.

As a numerical example let us assume that with the 1/999 shunt and the 1/10 megohm resistance, we obtain a deflection of 200 scale divisions, then the working constant is

$$200 \times 1000 \times \frac{1}{10} = 20{,}000.$$

In other words, 20,000 would be the number of scale divisions obtained were the entire current from the battery allowed to pass through the galvanometer with one megohm in series.



## A SIMPLE FORM OF RAILWAY POWER HOUSE LIGHTNING ARRESTER.

BY A. E. KENNELLY.

A simple and convenient form of central station lightning arrester, designed and installed by Mr. W. T. Cook, Manager of the Louisville Traction Company at Louisville, Ky., deserves some notice from those interested in street railway service. It does not involve any new principle, but is readily set up on the spot with the aid of a carpenter. It is illustrated in the accompanying illustration. A front elevation is shown at the left-hand side, and a vertical section at the right hand side of this sketch.

Upon the wall, WW, of the station, near the switchboard, is a box, XX, with nine vertical partitions, each lined with asbestos paper. Into this box pass three copper rods, a, a', and b. The two former are connected through switches, s, s', with a heavy copper conductor of 300,000 circular mils section, leading directly to the positive bus bar of the switchboard, immediately above the main generator switches. The lower rod, bb, is connected directly to the negative or main return bus bar by a copper conductor, No. 0000 A. W. G., without any intermediate switch. In any partition of the box, a No. 16 A. W. G. double cotton covered copper wire is hung, as shown at w, on the right hand side. The upper end of the wire is bared and is hooked around the rod, a, while the lower end of the wire is left covered and is allowed to rest by its weight on the ground rod, b. With the switches, s, s', closed, the full station pressure of 550 volts will be brought to bear between the rods, a and b, which are 10 inches apart, and thence upon the double thickness of cotton covering on the wire, w, at the contact with the lower bar. The cotton covering of the wire, w, is amply sufficient to stand a pressure of 550 volts indefinitely, but should an electrical disturbance of high pressure arrive at the station, due to a lightning discharge, the pressure will disrupt the cotton insulation and produce a momentary short circuit through the arc and the wire, w, between the positive and negative rods, a and b. The melting and volatilization of the wire takes place instantly, and the arc is almost instantly extinguished by reason of its being unable to sustain itself over the 10-inch gap.

The reason for the use of two separate

A SIMPLE LIGHTNING ARRESTER.

positive bars, a, a', is that a wire, w, can be replaced on either side by opening a switch on that side, and after the wire is in position the switch can be closed without danger of burning up the wire in the face of the operator. Eight partitions were used in this apparatus, so as to enable eight different wires to be used in parallel at the same time, but in practice only two wires were employed, one on each side.

Mr. Cook states that during the winter time the wires remain in position for months unaffected, but during a thunderstorm it is usual for one or both wires to be burned up. The flash is so soon dissipated that no trouble is experienced at the generators. Mr. Cook states that the apparatus has worked satisfactorily for more than five years.

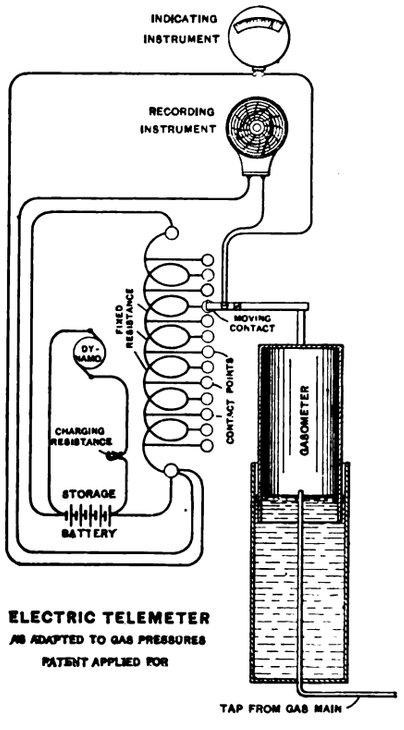
## SOLDERING ALUMINUM.

On account of the number of inquiries for directions for soldering pieces or wires of aluminum the following instructions are reprinted from the handbook of the Pittsburgh Reduction Company.

In advance it might be said that wire connections are best made by means of some form of coupling device such as the McIntyre joint, which is made of aluminum, for this purpose.

Soldering aluminum has so far proven a difficult task. Most solders, such as ordinary hard solder composed of silver and tin, or ordinary soft solders, composed of lead and zinc, will not stick, owing to the high heat conductivity of aluminum. The heat is very rapidly drawn away from any of the molten solders, causing them to freeze before flowing sufficiently. Good joints can be made, however, by carefully cleaning the surface to be joined, and with very hot soldering bits, or careful work with the blow pipe, "tinning" the surfaces with some of the special solder used, before attempting to join the metals; using special alloys for the solder. Several such solders are successfully used, pure tin with a little phosphor tin being the basis of the majority of such solders. Soldering bits of nickel are best to be used and specially good work has been done with those kept hot by a gasoline torch or electric appliance.

Special care should be taken to clean the surface to be soldered; this can be successfully accomplished by the mechanical means of scratch-brushing, scraping or filing the surfaces, thus exposing fresh metal free from the thin film of oxide of aluminum and the oxide of silicon (silica), which forms a protecting coating over the surface of the metal, preventing either the soldering or the plating of the aluminum.



Another way to clean the surface of aluminum for either soldering or plating is to dip the sheets into nitric acid diluted with three times its bulk of hot water, and which has had just enough hydrofluoric acid added to it to make the solution act on the surface of the metal, this action being denoted by the evolution of gas bubbles. The solution can be kept in either a wooden or lead-lined tank, and the amount of hydrofluoric acid added need be only small, say less than five, or, at most, ten per cent. of the bulk of the solution. The hydrofluoric acid required is the cheap fluid of commerce sold in lead jugs and costing about five cents per pound.

The aluminum, after being cleaned in this dilute nitric and hydrofluoric acid solution, is again dipped into hot water for rinsing and dried in hot sawdust; it is then cleaned so that either solder or plating solutions can be readily applied.

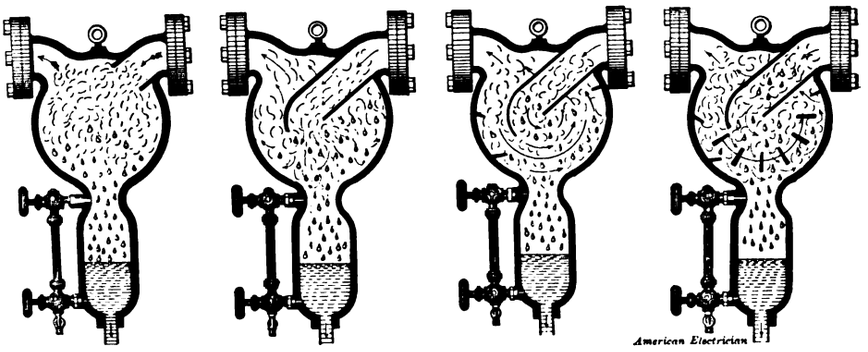
## THE USE OF ELECTRICITY IN GAS WORKS.

Mr. H. G. Field describes in "The Technic" an isolated plant installed under his direction for the Detroit City Gas Company. The plant consists of a small gas engine driving a dynamo supplying lights, particularly in such dangerous places as the Pintsch compressor room, tank house, purifier cellars and ammonia room, where artificial lights of other kinds would be out of the question, owing to the inflammable and explosive nature of the atmosphere. Keyless sockets are used, controlled by switches located outside, long extension cords with waterproof sockets and heavy lamp guards being provided to facilitate inspection in case of trouble in tanks, purifier rooms or other places where without them it would be necessary to work in the dark. An interesting piece of apparatus described in the same article is indicated in the accompanying diagram of connections. Its purpose is to



ELECTRIC TELEMETER
AS ADAPTED TO GAS PRESSURES
PATENT APPLIED FOR

indicate and record at any point the gas pressure as measured either on the premises or at any distant location. The instrument consists of a gasometer, to the bell of which is attached a moving contact sliding over contact points, connected, regulator-head style, to a resistance. A definite current is passed through this resistance by means of a constant potential, indicated in the figure by a storage battery. The difference of potential between the moving contact and the lower terminal of the resistance is proportional to the pressure, and this potential difference can be tapped off to indicating or recording instruments, or, as indicated in the figure, to both. The article states that the use of this arrangement for indicating or recording at a distance any pressures or positions has been patented.

## OIL AND GREASE EXTRACTORS.

There is hardly an imaginable situation where it is not possible to improve things by the use of grease extracting machinery in connection with steam boilers and steam using. The number of grease extractors now in the market is almost infinite, and it must be said that almost

I. By Expansion. II. By Reverse of Current. III. Centrifugal. IV. Baffle Plate.

FIG. 1.—TYPES OF GREASE EXTRACTORS.

every one of them possesses more than one point of excellence. There are numberless conditions met with in practice that require an almost endless variety of mechanisms to meet, and it is for this reason that the very many forms of grease extractors in the market are all necessary.

Many forms of extractors are made for grease alone, other forms are for water only, while many extractors work to separate both water and grease. Although there is an almost endless variety in form and appearance, all the separators work upon one or more of a few fundamental principles, and the several forms may be classified and divided into the following forms, viz.: Separation by expansion, by reverse of current, by centrifugal force and by baffle plates. The four engravings which constitute Fig. 1 represent

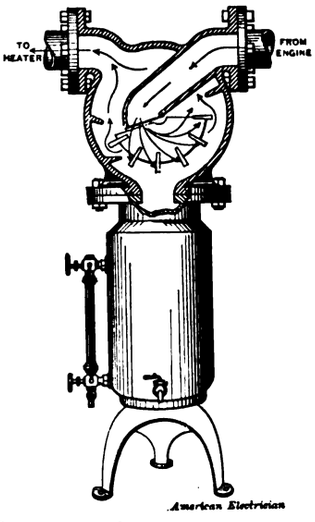


FIG 2.—JENNINGS' COMBINE OIL OR GREASE SEPARATOR.

types of these four methods, to which may be added the "Turkish Towel" separator, the "Drip Pan," the "Wire Screen" type, and a few other varieties which will develop from combinations of the varieties above noted, and which will be described and classified according to their characteristics.

For the above engravings we are indebted to a catalogue of Jennings Separators, published by the Watson & McDaniel Company, Philadelphia, Pa., which shows the methods noted above, and also a combination of the four methods into one separator, shown by Fig. 2, and known as the Jennings' Combined Oil or Grease Separator. This device is said to be free

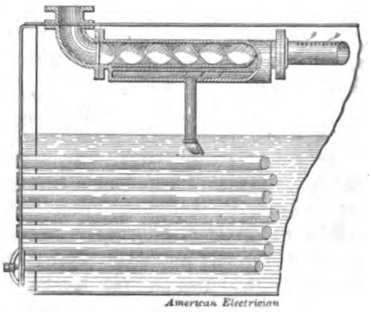

FIG. 3.—MOSHER SEPARATOR.

from back pressure, and is made either vertical or horizontal.

The centrifugal class is perhaps the largest, therefore we will give attention to that first. But the centrifugal type may be subdivided into quite a number of separate and distinct divisions accordingly as the grease is thrown off tangentially or spirally. Figs. 3 and 5 will illustrate this point. Fig. 3 shows the spiral form of grease delivery, and Fig. 5 presents the tangential principle in one of its many forms.

The form of apparatus shown by Fig. 3 may be a boiler fixture or it may be placed for different kinds of duty in lines of steam or exhaust pipes. This device is known as the Mosher Separator, and is manufactured by Charles P. Mosher, New York City. When placed inside the boiler, its office is solely to separate water from the dry steam. This is also its function when placed in a steam pipe, but when connected into a line of exhaust piping, oil and water both will be separated from the uncondensed steam. Fig. 4 shows the

Digitized by Google

method of applying this separator in a line of pipe to remove either steam or oil, and the engraving also illustrates the action of the separator so as to make it easily understood. This engrav-

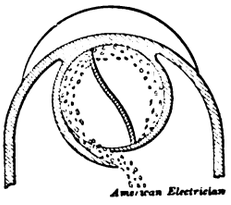

FIG. 4.—ACTION OF SEPARATOR.

ing shows the spiral by means of which a whirling action is given the flow of steam in the pipes, and the manner in which the oil and water are thrown out by centrifugal force during the whirling action mentioned, and it is also shown how the water and oil are "peeled" or

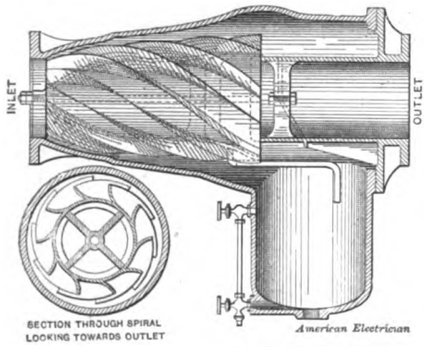

FIG. 5.—DE RYCKE GREASE EXTRACTOR.

"shaved" from the dry steam by action of the edge, which in this separator is a special point.

Another form of "centrifugal" grease extractor is shown by Fig. 5—the De Rycke, made by Joseph De Rycke, of New York City. This separator consists, as shown, of a casing in which

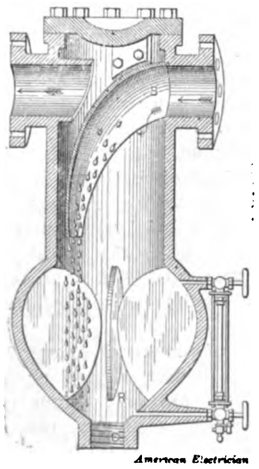

FIG. 6.—LIPPINCOTT OIL EXTRACTOR.

is a hollow cone fitted with knife-edged spiral wings. The space between the shell and cone at its smallest part is equal to the diameter of the exhaust pipe, and the space between the cone and the outlet is greater in area than that of the exhaust pipe. On entering the extractor, the steam is thrown outward by the cone and given a centrifugal motion by the wings. At the end of the cone the motion of the steam is reversed and the heavier particles are thrown to the outward end of the shell and into the cone, whence they are carried off by a suitable pipe. The cone is stationary and is held securely by lugs.

Fig. 6 shows another type of the inverted syphon extractors, but there is added a baffle plate, placed vertically which prevents the steam from distributing the water, and possibly splashing it back into the upward column of steam, in which it might again be caught and again carried on by the steam. A large area is provided around the radial, vertical baffle plates, in order that steam may pass with the least possible disturbance or loss of pressure.

In the Lippincott Separator the water strikes a curved deflector, without any tendency to spray, and is instantly deflected down to the reservoir, while the steam readily passes around the sides of the deflector. The action of the two types of separators shown may be demonstrated

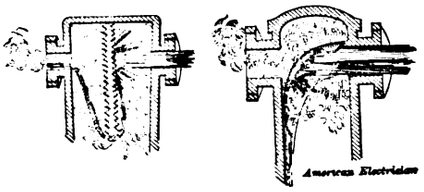

FIG. 7.—THE "WRONG WAY."

FIG. 8.—THE "RIGHT WAY."

by means of two sheet metal plates, one flat and one curved, held under any convenient water faucet.

The manufacturer of this separator illustrates this point by the two engravings presented herewith, as Figs. 7 and 8. In Fig. 7 is illustrated what Mr. Lippincott calls the "wrong way," and in Fig. 8 he presents his "right way." In the first

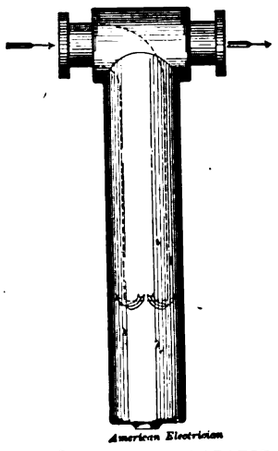

FIG. 9.—CLIMAX SEPARATOR.

engraving the steam and grease is shown impinging directly against a flat baffle plate, the oil flying off in every direction, only to be caught again to a great extent by the current of steam and carried on with the vapor again. In Fig. 8, the "right way," the extracted oil is carried down to the receiver by the guide, which is really a curved baffle plate. The full title of the device shown by Fig. 6 is a "Steam Separator and Exhaust Grease Extractor." It is made by A. C. Lippincott, New York City.

Probably the simple form shown by Fig. 9, which represents a Climax Separator made by Best, Fox & Co., Pittsburgh, Pa., is the fundamental form of most of the oil separators, both centrifugal and otherwise. In this form there is simply a pipe within a pipe, the steam entering the smaller, passing into the larger in a downward direction, centrifugal force acting at this point serving to carry the grease down into the reservoir while the steam makes the turn and escapes through the pipe to continue its

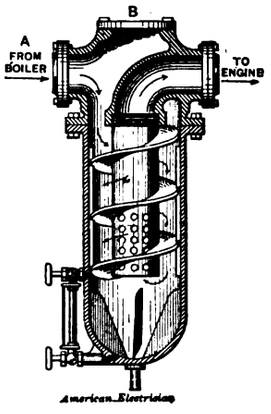

FIG. 10.—SIMPSON SEPARATOR AND TRAP.

journey to the engine. Upon the simple fundamental form there has doubtless been built most of the grease extractors now in the market—all the centrifugal, and many other forms besides.

A development of the centrifugal extractor is shown by Fig. 10, which represents the Simpson, made by the Keystone Engine & Machine Works, Philadelphia, Pa., in which, the steam taking a spiral course between the threads, causes the water and grease to be thrown by centrifugal force against the outer walls,

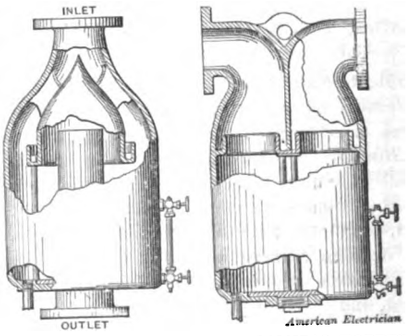

FIG. 11.—VERTICAL AND HORIZONTAL HOPPER OIL ELIMINATOR

while the dry steam goes through the small holes to center of pipe. Steam can enter either at A or at B, as convenience may require, and the water column at the bottom shows the quantity of water in the reservoir at all times.

There is a very close connection be-

Digitized by Google

tween the centrifugal extractors, especially when they are assisted by gravity as in the case of Fig. 9, and some of the inverted syphon and baffle plate types. In fact, Fig. 9 may be called an inverted syphon concern, and it may also be termed a "baffle plate" construction if it be allowed that the "plates" are rolled into tubes—the effect is the same, it is only a difference in the details of construction.

Fig. 11 may be included in the inverted syphon type, but aside from this there is a very important feature in the gutters shown in the engravings, said gutters being always filled with water, which intercepts all entrained water and grease. In the vertical type the steam enters the device at the top and the water or oil fol-

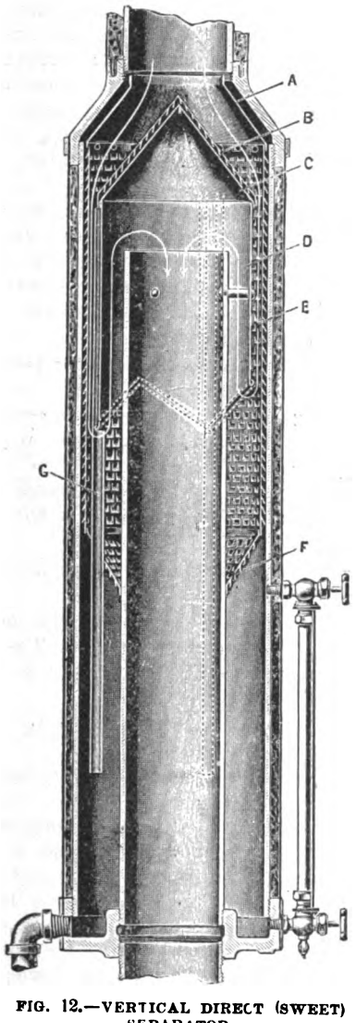

FIG. 12.—VERTICAL DIRECT (SWEET) SEPARATOR.

lowing the surface passes to the bottom of the separator and is intercepted by the water. The water or oil in the steam not following the surface will strike the exterior of the cone and will be caught by the gutters at the bottom of the cone and carpipe. In the horizontal separator the steam may enter at either side, both being alike. In this separator, as in the vertical, the water or oil is caught by the gutters and carried to the bottom by the pipes shown.

One of the most important features of this device is that it is so designed that the steam is gradually expanded into a chamber ten times the area of the pipe and on its outward passage is gradually reduced back again to the original area. This arrangement reduces the velocity of the steam in the working part of the separators to one-tenth of that in the pipes, and it is claimed that the separation takes place with the least possible amount of friction, the interior of the separators being perfectly smooth. These machines are manufactured by the Hoppes Manufacturing Company, Springfield, Ohio.

Quite different in principle, and loaded with additional grease catching apparatus, is the "Direct" Separator made by the Direct Separator Company, Syracuse, N. Y., and illustrated by Fig. 12. This device combines in the most admirable manner not only the centrifugal, but the baffle plate, the perforated plate and perhaps several other methods of grease and water extraction. The inverted syphon is there, as the engraving shows, and at the very instant of the "whip-snap" which the steam makes as it passes the bottom of the syphon, the centrifugal force developed throws the water and grease into or upon a perforated screen.

Other forms of separators will be discussed in succeeding articles.

## Letters on Practical Subjects

### A Peculiar Arc Line Trouble.

*To the Editor of American Electrician:*

Sir.—Answering Mr. Hervey Scofield's communication appearing in the July issue, I will say that the same trouble happened here, that is, opening and closing without apparent cause, but we found a loose connection on one of the switch blades, and if Mr. Scofield will examine his dynamo and switchboard connections I think he will probably find his trouble. If not, I would recommend examining the hanger boards.

Geo. M. Ockford, Jr.

Ridgewood, N. J.

### The Telephone as a Burglar Alarm.

*To the Editor of American Electrician:*

Sir.—I have lately made use of some telephone apparatus for an alarm system, a description of which may be of interest to your readers.

A bank vault was connected up to a room of one of the officials in the same building so that any one attempting to enter when switches are on would turn in an alarm. In the vault is a very sensitive telephone transmitter, the primary current of which is controlled from the receiving end. At the receiving end is a complete telephone and necessary switches. When an alarm comes in, the person at the receiving end puts current through primary of induction coil of vault transmitter and with his receiver can hear distinctly the slightest noise in or near the vault. A simpler alarm has been used, but it was found that false alarms came in. With the present arrangement it is positively known that the vault is being tampered with before calling the police. The alarm is used at night only.

A. H. Ingraham.

South Chicago, Ill.

### Brush Discharges from High Tension Lines.

*To the Editor of American Electrician:*

Sir.—I noticed in the July number of your paper, page 354, vol. XI., an inquiry signed by S. D. W., relating to high potential transmission and insulation, with some points in the answer of which I beg to differ.

The Telluride Power Transmission Company of this city has for two years been successfully operating a 1000-h. p. three-phase alternating plant, transmitting power to Mercer, a town about 55 miles distant, at a potential of 40,000 volts. The line is of bare copper wire, No. 5 gage; triple-petticoat glass insulators are used, and there are no brush discharges of which you speak. The loss is very small.

Robert Fairbanks.

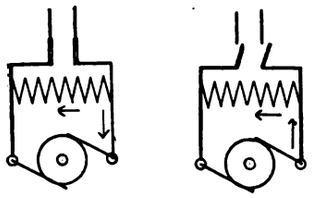
Telluride Power Transmission Co., Provo, Utah.

### To Find the Turns in the Shunt or Series Coil of a Compound Dynamo.

*To the Editor of American Electrician:*

Sir: In testing dynamos it is sometimes necessary to find the number of turns in the shunt or series winding without unwinding the coil. The writer while experimenting with some dynamos, devised the following wrinkle. If the machine is a compound wound, one or the other of its windings is likely to be known and by a simple method the other can be found. All that is required is a good voltmeter and ammeter. The dynamo is driven at a constant speed, and a voltmeter is put across the brushes. An ammeter is connected in series with the coil in which the turns are known, a measured current is sent through this coil and an e. m. f. will be generated which will be read on the voltmeter. Next a current is sent through the unknown coil until the same e. m. f. is obtained. If we have the same e. m. f. we must have the same magneto-motive force in ampere turns. Multiplying the turns in known coil by the amperes we get the ampere turns, and this divided by the current in the unknown coil will give the turns in the unknown coil. For example, a compound-wound machine with 50 turns in series coil and a current of 200 amperes gave a voltmeter reading of 25 volts. It required 5 amperes to produce the same reading of 25 volts in the unknown coil. The ampere turns of the known was $200 \times 50$, or 10,000 ampere turns, and as the unknown must have been the same, dividing by the current in unknown winding gives $10,000 \div 5$, or 2000 turns in unknown.

Leslie E. Carpenter.



New York City.

# Electrical Catechism

*366. How is the magnetization of a shunt motor maintained after the line current is cut off?*

The magnetizing current is caused by the e. m. f. due to the rotation of the armature in the magnetic field. When the motor is driven by current from the line, an e. m. f. is generated in its armature just as in a dynamo. When the machine is running as a motor, this e. m. f.

is in a direction tending to prevent current from passing through the armature from the line. When the line current is cut off for any reason, the motor e. m. f. sends current through the field coil in the same direction as the previous current from the line, as indicated by the arrows in the figure at the right. (The direction of the currents from the line is shown in the figure at the left.) The motor then acts as a shunt dynamo, exciting its own field until the speed drops off.

*367. Is the motor e. m. f. of any practical importance?*

It is of great importance in the operation of the motor. Early inventors tried to get rid of it, but it was soon found that the motor e. m. f. was necessary for the efficient operation of an electric motor.

*368. Why did inventors try to get rid of motor e. m. f.?*

Because it limits the current through the motor. They reasoned that the power delivered by the motor was proportional to the current taken. But they found that the motor e. m. f. was in such a direction as to oppose the current (for which reason it is often called a "counter electromotive force," or "c. e. m. f."), and so they tried to make motors that would not develop much c. e. m. f. Such motors were found to take more current, as was expected, but they did not develop the desired power.

*369. Does Ohm's law apply to the current taken by a motor?*

It does when properly applied. The current through the armature of a shunt motor equals the difference between the line and counter electromotive forces divided by the resistance of the motor armature (including resistance of brushes and commutator). The current through the field of such a motor is simply the pressure divided by resistance.

*370. Why do motors with small c. e. m. f. develop but little power?*

Because the same elements in a motor that cause it to deliver power are also the elements causing the c. e. m. f. In fact, it is now understood that the power given out by a motor equals the product of the current by the c. e. m. f.

*371. What determines the power given out by a motor?*

The power depends upon the pressure and current supplied to the motor, the current being regulated by the amount of work put upon the motor, as will be explained. In order not to get into too great complication at first, it may be presumed that the motor has a steady load and is working properly. The work being done by the motor and the electrical energy taken from the line may then be analyzed.

*372. What elements compose the power delivered by the belt of a motor?*

The mechanical power equals the product of the speed by the pull on the belt. For example, if the belt is running at 55 ft. per second, and the pull on the belt (or rather the difference between the pulls on the tight and loose sides of the belt) is 10 lbs., the power is 550 foot-pounds per second, or 1 horse power. Making allowance for small losses in friction and in heating the iron core of the armature, the product of belt speed by pull equals the product of the pull on the armature wires multiplied by the speed at which they move. (In the case of toothed armatures, the pull comes upon the teeth more than upon the wires themselves, but the theory may be extended without great difficulty to cover that case.)

*373. What elements make up the pull on the armature wires?*

The pull on each wire (measured in dynes) equals the product of current by strength of field by length of wire in the magnetic field. The pull upon the whole armature is the product of the number of wires by the current through the armature by the effective number of magnetic lines of force through the armature divided by 3.14 times the diameter of the armature. (See also Nos. 332, 333 and 334, Amer. Elec., XI., 432, Sept., 1899.)

*374. What elements make up the velocity of the armature wires?*

The velocity equals the number of revolutions by the distance around the armature. The latter is, of course, the circumference of the armature (considering the average position of the wires) and is 3.14 times the average diameter.

*375. What elements compose the power delivered to the shaft or pulley of the motor?*

This equals the product of the pull upon the armature wires multiplied by their speed. In multiplying the factors of the two elements, as given in Nos. 372 and 373, it is seen that "3.14 times the diameter" multiplies one factor and divides the other, so that the two cancel. The final product for the work is: Armature current multiplied by number of armature wires by effective number of magnetic lines through armature by number of revolutions per second.

*376. What elements compose the counter electromotive force?*

The counter, or motor, e. m. f. equals the rate of cutting lines of force and is the product of the number of armature wires by the number of revolutions per second by the effective number of magnetic lines of force through the armature. (This gives the e. m. f. measured in the absolute or "C. G. S." unit, which is only one one-hundred-millionth part of a volt.)

*377. What is the relation between power and counter electromotive force?*

From Nos. 374 and 375 it is seen that the power equals current multiplied by the product of wires by revolutions by lines of force, which equals current by counter electromotive force. Thus it is seen that while the c. e. m. f. limits the current, it is one of the factors of the power. (In the case of alternating current motors, the power of the motor equals the product of current by the part or component of the c. e. m. f. which is in phase with current, this product being multiplied by another factor depending upon whether it is a single phase, two phase or three phase system.)

*378. For what sort of a motor does the above reasoning apply?*

For simplicity, the above has been developed only for a bi-polar direct current motor, but the argument might be modified to apply to any kind of a motor, and the general conclusion applies to any electric motor.

*379. What units were used in the above argument?*

For simplicity, the units of the metric or "C. G. S." system were used. The conclusion, however, in No. 376 is independent of the units used.

*380. What is meant by "effective magnetic lines of force"?*

In a dynamo or motor the brushes are so set, or the magnetic field is so distributed, that the e. m. f. in some of the wires is in the opposite direction to that in the rest. Sometimes this is to diminish the sparking at the brushes, or is due to incorrect design or to improper resetting of the brushes. For this reason the effective number of wires or of magnetic lines is less than the total. We may consider either that not all the wires are effective, or that not all the lines are such.

*381. Does the power delivered by a motor increase as the c. e. m. f. increases?*

The two vary inversely so long as the c. e. m. f. is more than half of the line e. m. f. This is because the current is controlled by the c. e. m. f., being equal to the difference between the line voltage and the c. e. m. f. The power equals the product of current by c. e. m. f., and it follows that the power increases as the c. e. m. f. decreases, so long as the difference between the two e. m. f.'s increase faster than the c. e. m. f. decreases.

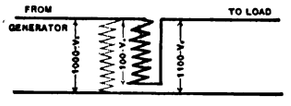
# Queries and Answers

Is there any difference in the horse-power that can be obtained from a gasolene engine at an elevation of 1200 ft above sea level and the power that it will give at sea level? How much will a gasolene engine that gives 35 brake horse-power at sea level lose at an elevation of 1200 ft., using the same grade of gasolene and other conditions remaining the same. O. W. J.

The power of a gasolene engine depends upon the amount by weight of explosive gases that can be gotten into its cylinders. With reduced barometric pressure this weight will be proportionally reduced, but the reduction at 1200 ft. is so slight as to be almost negligible. While the pressure of the atmosphere at sea level is 14.7 lbs. per sq in., at an altitude of 1,200 ft. it is 14 lbs., giving a difference of only about 5 per cent. A 35 h. p. gasolene engine might be expected to give fully 33 h. p. at this elevation. Such engines are generally rated with a margin of about 10 per cent. of reserve power above their rated power to cover variations in quality of fuel, etc., and they will rarely fall below their rated power, due to reduced air pressure, except at elevations of several thousand feet.

Please explain how I can excite an alternator from a 500-volt direct-current generator. H. C. L.



You can temporarily excite the alternator by connecting its field in series with a suitable resistance across the 500-volt mains. The field of the alternator is undoubtedly wound for 110 volts, so that you will have to absorb about 400 volts in the series resistance, i. e., it will have to have about four times the resistance of the field winding to be excited. A good temporary resistance for this purpose is a water rheostat. Of course this method is too wasteful to be kept in service. If you wish to regularly excite your alternator in this way its fields should be rewound with wire of about ¼ the present circular mils (6 numbers finer on the Brown & Sharpe gage) and 4 times the present number of turns. The winding will then have 16 times as great a resistance as at present and with about four times as great a voltage will take about ¼ the present current; thus 4 times the present number of turns will give the same ampere turns and the same excitation.

How do you find the number of circular mils in a given bar of copper such as a bus bar? F. M.

The number of circular mils in a bar of copper can be readily found if the bar is of circular cross section. In this case the number of circular mils is the square of the diameter of the bar in thousandths of an inch. For instance, the diameter of a ½ in. bar is 500/1000 and the number of circular mils is the square of 500, i. e., 500 x 500, or 250,000 mils. A 1-in. bar has a diameter of 1000/1000 and its cross section is 1000 x 1000 or 1,000,000 circular mils. The cross section in circular mils of rectangular bus bars is more difficult to determine. It is most easily calculated by remembering that one square inch is equal to about 1,720,000 circular mils. Knowing the cross section of a bar in square inches, therefore, multiply it by 1,270,000 and the result will be the cross section in circular mils.

(1) How should I connect a transformer on a 1000-volt circuit to boost the voltage? Does this effect both sides of the line or only one? (2) I am desirous of using some transformers wound for 1000 volts on a 2000-volt circuit; would it be practical to connect the primaries of two transformers (which are from one to two poles apart) in series, using single-pole fuse blocks, the secondaries connected in multiple as in the case of the 1000-volt circuit? E. B.

(1) A transformer used for boosting the pressure of a 1000-volt circuit should be connected up according to the accompanying figure, the primary being connected across the incoming circuit, one terminal of the secondary to terminal of the primary and the other terminal of the secondary to one side of the outgoing circuit, the other side of the outgoing circuit being connected to the opposite side

THE CONNECTIONS OF A TRANSFORMER FOR BOOSTING THE VOLTAGE.

of the incoming circuit and the primary. In this way the 100 volts set up in the secondary of the transformer is added to the 1000 volts, making the voltage delivered beyond the boosting arrangement 1100 volts. The best way to determine which end of the secondary to connect to the primary and which end to connect to the line is to try it one way and see whether it boosts or depresses the voltage. If the voltage is depressed the connections of the secondary should be reversed. This arrangement—although the boosting is done on one side of the line—affects the voltage between the two sides of the line so that it cannot be said to affect one side more than the other. (2) Yes, it would be practicable. The two transformers used together in this way should of course be of about the same capacity because the same primary current goes through the two in series, making the output of both the same, and if one transformer is larger than the other its useful capacity will be limited to that of the smaller.

(1) What other causes are there besides the friction of the brushes upon the commutator that cause the "humming" or "singing" of motors or dynamos? (2) How can this singing be remedied? (3) In an iron-clad armature, what effect upon the efficiency of general properties of the machine does the number of slots have? For instance, for a thirteen (13) inch armature text-books recommend about sixty (60) slots, while the writer has known armatures of this size with but thirty-five (35) slots to be very satisfactory. (4) With a given number of commutator bars or a given number of coils, what is to be recommended, a few slots with several coils per slot or a greater number of slots with fewer coils per slot, and what considerations govern the best proportions?

(1) The humming or singing is in part due to the passage of the armature teeth under the pole tips and (2) may be reduced by rounding the latter, although this course is likely to interfere somewhat with good commutation. (3) The more slots there are the less is the magnetic reluctance of the air gap and the less is the iron loss in the pole pieces if the latter are solid. The commutation is also improved by increasing the number of slots up to the number of commutator bars at least. (4) A greater number of slots with fewer coils per slot is more expensive, but preferable.

I am connected with a street railway having poor rail bonds and a heavy drop in the line. I have taken one-minute readings from end to end of the line and return, a distance of 16 miles, on both voltmeter and ammeter showing voltage ranging from 550 volts down to 250 volts and current from zero to 200 amperes. To calculate the horse power would it be correct to use 746 watts per h. p., or a larger number? Could you suggest any other useful data I could figure out from these readings beside h. p.? How about track resistance; could it be obtained? J. W. B.

I presume that the one-minute readings on voltmeter and ammeter were the readings of the voltage obtained on and the current used by a car. To calculate the horse-power absorbed by that one car the voltage at any one reading should be multiplied by the current at that same reading. The result divided by 746 will give exactly the number of electrical horse-power that that car at that instant absorbed from the line. The total amount of power required at the power house for that one car would be the number of amperes going through the car multiplied by the power-house voltage at that instant, divided by 746. Other data that would be of value to you are the drop and waste of power and the track resistance. The maximum drop, viz., that at the end of the line most distant from the power house, is the difference between the voltmeter reading at the station and that of a voltmeter located at the distant end of the line. This can be obtained by taking a voltmeter out to the end of the line and making a number of readings at certain definite times and instructing the power house attendant to read the voltmeter there at exactly the same seconds. The drop will be the difference between the two voltmeter readings. This maximum drop, if the feeders are fairly uniformly loaded, will be twice the average drop. If the maximum drop is 275 volts, the pressure at the power house being 550 volts, 50 per cent. of the power sent to the end of the line is wasted, and if the average drop is half of this 25 per cent. of the power sent to all the cars is wasted in line and track resistance. If the amount of the drop in the line can be figured from its resistance and the current flowing in it an idea of the drop in the track circuit can be obtained by substracting the drop in the line from the total found by voltmeters as above.

## THE STANDARD AUTOMATIC GAS ENGINE.

Many electrical engineers have an idea, born of sad experience, that the gas engine is inherently unsuitable for the driving of dynamos—at least with rapidly varying loads. At an earlier stage of electrical development, when the steam engines had been used for this purpose no more than has the gas engine at the present day, the average steam engine was fully as deficient in the qualities of steady and economical operation over a wide range of loads. The tremendous possible field of application of a prime mover as economical of space, first cost, attendance and fuel, as is the internal-combustion engine, compared with the steam engine and boiler, has concentrated effort, time and money on the cure of the failings of the gas engine, and this concentration is now bringing forth new gas engines as perfect for electrical service as are the steam engines developed a few years in advance of them.

One of these engines is that with the name which heads this article, and built by the Standard Automatic Gas Engine Company of Oil City, Pa. While the company is comparatively unknown as yet to the majority of present or prospective gas engine users, and while many of the details of the engine as described below are radically novel, the fact that neither the company nor the engine is in inexperienced hands is proven by mentioning the name of the president of the one and the designer of the other, Mr. J. W. Raymond, designer of the improved Raymond engine built for many years by the J. I. Case Threshing Machine Company.

The engine operates upon the familiar Beau de Rochas, or four-stroke cycle, commonly known as the Otto, giving per single-ended cylinder one impulse during two

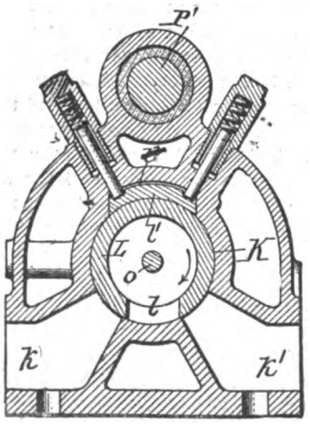

FIG. 1.—CROSS SECTION OF VALVE.

revolutions. The special features deserving, perhaps, first mention, are the valve and valve gear. There is only one valve for both admission and exhaust, and this valve is a hollow cylinder of cast-iron, chilled and ground. The interior of the valve is open to the engine cylinder and as the valve turns in the valve chest, an opening in the valve alternately connects the cylinder with an admission and an exhaust port. A cross section through this valve is shown in Fig. 1. L is the cylindrical valve rotating in the valve chest, K, and held up against the valve seat by the springs and piece, l'. As it rotates, the port, l, connects the interior of the valve—which is open to the cylinder—alternately with the admission chamber, k, and the exhaust chamber, k'. The valve does not oscillate or have a reciprocating motion of any kind, but simply rolls continuously around in one direction, being turned by a horizontal shaft, driven by mitre gears from the main shaft, and turning the valve stem by 2 to 1 spur gears. The absence of poppet valves, cams, springs, and so forth, makes the engine remarkably noiseless.

The ignition is electrical in character, accomplished by a wiping spark between wide tool-steel electrodes. The moving contact simply rotates with the valve, and the stationary contact is held by springs outside the valve chest and adjustable while the engine is in operation.

The governing of this engine is not accomplished by missing impulses, but by varying the quantity of the charge by throttling. The mixture is throttled by one plain balanced butterfly valve as simple as the damper in a stove pipe and almost entirely free from friction, since all points of the butterfly, except the stem, are out of contact with the walls of the valve chamber except when the valve is shut tight. For this reason the force which the governor must apply to move the valve is much less than that required for piston or other forms of valves, the leverage and necessary extent of motion of the fly balls is reduced and the regulation is correspondingly perfect. The proportions of the mixture are determined by entirely independent valves in the incoming air and gas pipes, the constituents being pulled through these and the mixture being pulled through the governing valve by the suction of the filling stroke.

The engine is horizontal and in small sizes, 15 h. p. and upward, is of the ordinary single-acting form, with a trunk piston acting as a cross-head. In sizes of 50 h. p. and up, the engine is made with two single-acting cylinders tandem on the same piston rod. The cycles of the two cylinders are displaced one revolution from each other, so that one impulse per revolution is obtained, the expansion stroke in one cylinder occurring immediately before the compression stroke in the other.

Naturally, some means must be devised for cooling the piston rod, which runs out through the explosion chamber of the cylinder nearer the crank to the piston of the other cylinder. The piston rod is extended out through the head of this cylinder also, in the form of a tail rod, and is made hollow. A long pipe is then inserted into the hollow rod and is packed at the tail rod end. Cooling water is injected through this long pipe clear into the rod in the second cylinder and flows back inside the rod, but outside the pipe, to a drip at the tail rod end. The piston rod is packed with non-inflammable packing where it comes through the cylinder head.

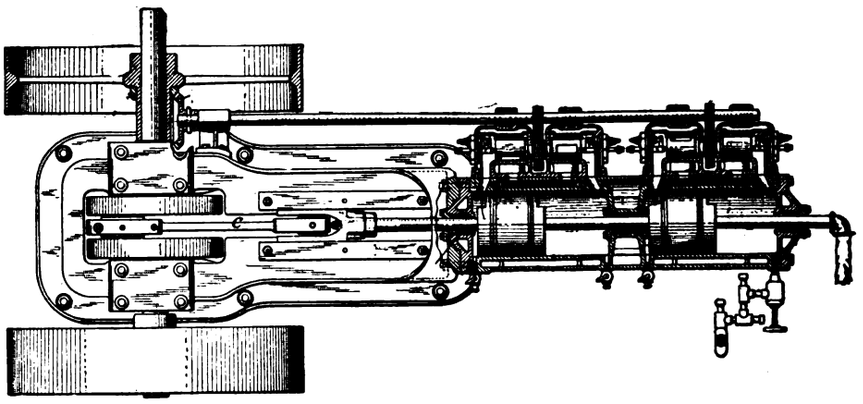

FIG. 2.—PLAN OF TWO-CYLINDER DOUBLE-ACTING ENGINE.

The company has recently completed a still more interesting engine with two 18-inchx18-inch double-acting cylinders, tandem on one piston rod, with outside cross-head of standard steam engine construction. The two double-acting cylinders give two forward impulses per revolution simultaneous with the compression strokes in the other end of the cylinders. The heavy compression both ways gives very smooth running, even with considerable slack in the cross-head and crank-pin boxes. The piston rod of this engine, owing to the heavy strains it is called upon to bear, is made of nickel steel, drawn with the hole for the cooling water in it. The water in this case is introduced through the cross-head and discharged through the tail rod. One balanced-pressure sight-feed lubricator on the center of each cylinder lubricates the pistons with a high fire-test engine oil. Fig. 2 shows a plan of this engine.

The pistons are cored out and the water passing through the rod is compelled to circulate also inside the pistons, thus cooling them. One horizontal shaft runs along beside the cylinders and turns the four valves of this engine (one for each end of each cylinder) through two pairs of cut gears. The governor actuates one butterfly valve, which throttles the mixture to

Digitized by Google

all four cylinder ends. The course of the mixture to any one, two or three of the four cylinder ends may be cut off to increase the compression and economy at low loads. Indeed, any valve chest may be opened and the igniter taken out while the engine is running.

This engine is started by turning it over to the proper point and igniting electrically a charge of very slow burning powder in an enclosure connected with one cylinder head. The connection is made through a number of right-angle bends made in capped tees in such a way that the ash from the powder blows past the bends and is caught in the caps, from which it may be removed from time to time. The engine may also be piped to a compressed air tank or steam supply for starting.

This engine is shown in Fig. 3 set up and belted to a 150-kw. Westinghouse generator for the Oil City Street Railway. A duplicate is under way for the same purpose, and two of 500 h. p. each are under order. No storage batteries will be used.

The engines are rated on the basis of mean effective pressure, the one shown in the illustration being conservatively rated at 200 h. p. on the basis of a mean effective of 32 pounds per square inch, although much higher mean effectives may be obtained. Indeed, this engine is guaranteed to develop 300 brake h. p. with a consumption of not more than 3000 cubic feet of natural gas per hour, this gas showing about 990 B. T. U. per cubic foot.

An interesting equipment of engines for which the company has closed a contract will consist of four like that shown in the illustration, which are ordered for use in Germany. These will be made into two engines by coupling two of them together with cranks at quarters, each complete engine thus consisting of two pairs of tandem double-acting cylinders giving four impulses per revolution. Each such engine will be direct coupled to a three-phase 60-cycle alternator mounted between the cranks, and these alternators will be run in parallel and with rotary converters. Another order is for two engines of 350 h. p. each, to carry a street railway load in western Pennsylvania. These engines will get their gas from by-product coke ovens, a gas which is at present thrown away, and will require no elaborate preparation such as washing or scrubbing to adapt it for use in the engines. All it needs is to be passed through holders in which it can deposit its tar.

The Standard Automatic Gas Engine Company, of which Mr. Raymond is President, as noted above, is capitalized at $36,000, but expects to increase its capitalization to $100,000 to accommodate increasing business. It has recently erected new shops on the bank of the Allegheny River, about two miles below Oil City. The building contains also the new street railway gas engine power house and is about 180 feet long by 67 feet wide. The contract will soon be let to lengthen it 150 feet.

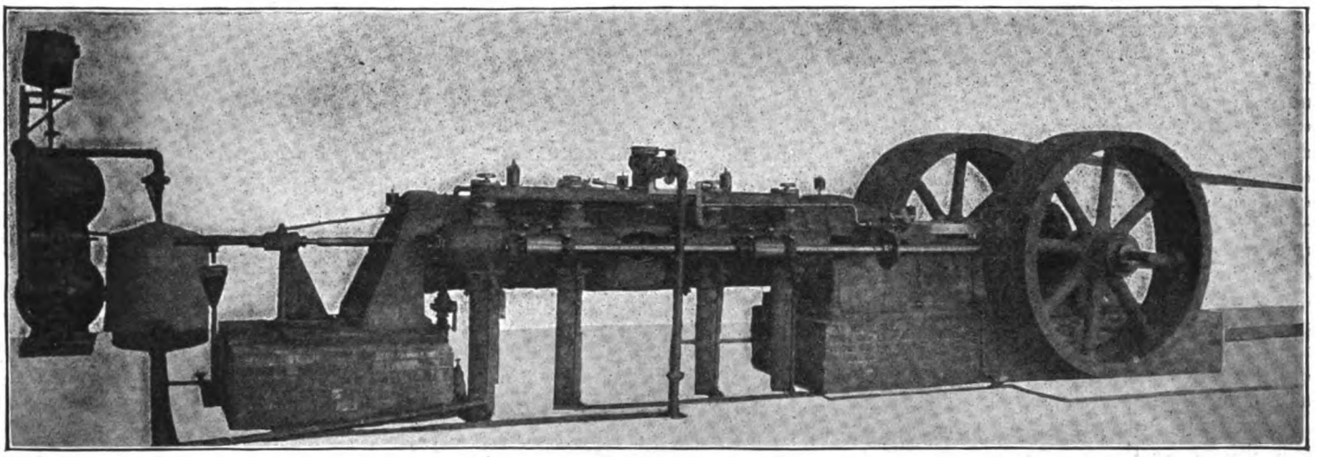
## A NEW WORKS FOR MAKING HIGH-WOUND MAGNET COILS.

The apparent paradox is often observed that the simpler an article of manufacture the more complicated is the machine designed to produce it. This is due to the fact that the very simple products are made in enormous quantities, and are turned out complete by automatic machines much more complicated than any tools used in the handiwork of more elaborate products. An interesting example of this is one of the simplest operations in the electrical arts, that of winding fine magnet coils. The work carried out on a very large scale involves automatic machinery, resembling that of textile establishments. An interesting instance of such an equipment is contained in a new building which the Varley Duplex Magnet Company has recently completed in Jersey City to accommodate its constantly increasing demands. A description of this new plant and the peculiar process of magnet winding brought to such a high stage of perfection by this company may be of interest in connection with the commencement of work in the new quarters.

The new works consist of a five-story building 50x25 ft. in plan, which is unique in that it is constructed almost entirely of concrete with an extremely small amount of either wood or iron. This construction was adopted to give an absolute protection against fire for the elaborate automatic machines described below. The concrete structure was built just as is a concrete dam, i. e., by means of knock-down frame forms or moulds, between which the mass is thrown and tamped. The floors, which are designed to carry 800 lbs. per square foot, are of concrete integral with concrete beams and cross-beams. The beams are of an inverted T section, the downwardly hanging head of the T serving for a convenient support of shafting or other apparatus in the room below.

While at present the company has a capacity of some 8000 standard telephone bridging bell magnets of 10,000 turns each per diem, the full capacity of the new works when the machinery is entirely installed will be 20,000 such magnets. The company has given up all branches of magnet making except the mere winding of the coils, for which the president of the company, Mr. R. Varley, and his engineers have designed some extremely ingenious automatic machines, a description of the operation of which may be given as follows:

As the users of the Varley duplex magnets know, the magnet wire itself is not wrapped with an insulating cover but the insulation of the wires of each layer from each other is accomplished by means of a silk thread wound between the bare copper turns, while the insulation of the layers from each other is accomplished by means of a thin sheet of paper inserted



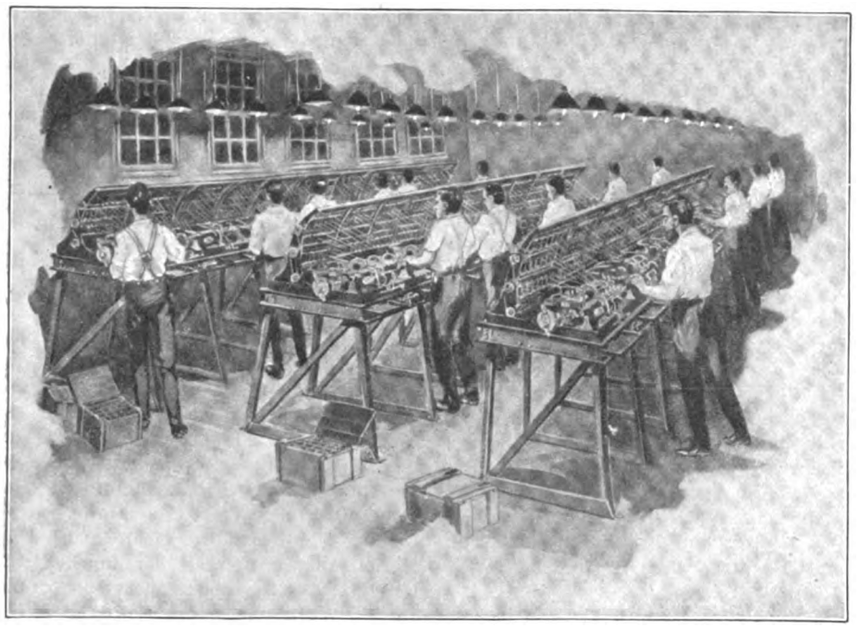


FIG. 3.—VIEW OF 300-H. P. ENGINE AT WORK ON RAILWAY LOAD.

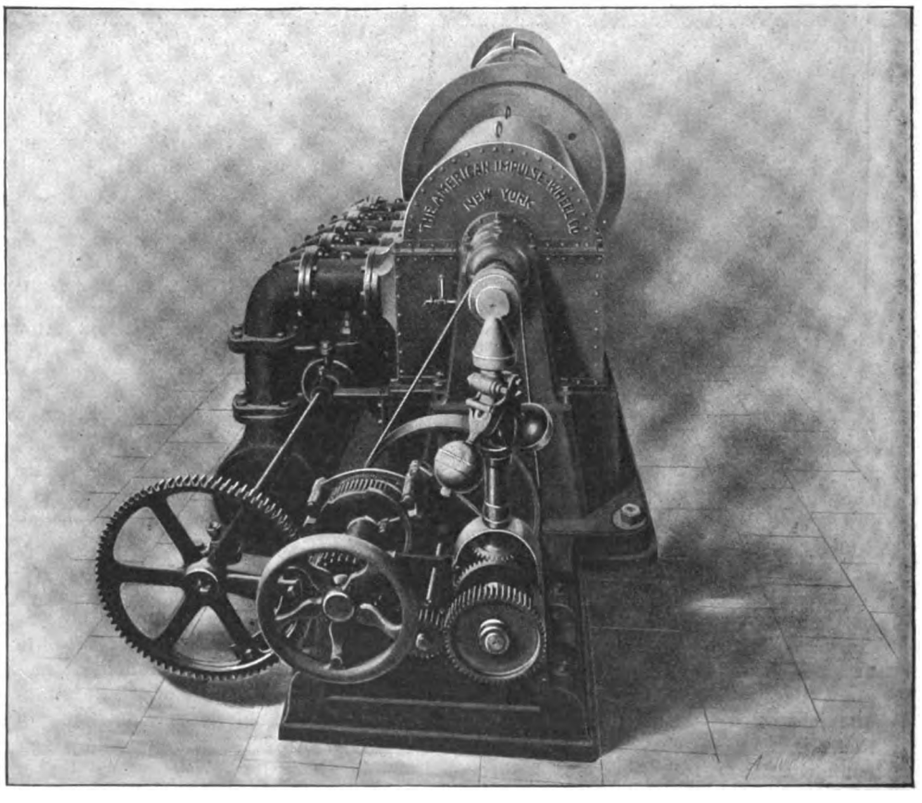
Digitized by Google

A VIEW OF SEVERAL VARLEY MULTIPLE AUTOMATIC WINDING MACHINES, EACH CAPABLE OF WINDING OVER 10,000,000 TURNS OF WIRE PER DAY.

after the winding of each copper wire and silk thread layer is finished. Each machine that makes these coils does not simply wind one coil at a time, but winds a tube of coils with a length of one foot, which may be divided up into as many as 12 coils. If the coils are 2 inches in length, six of them may be wound simultaneously; if 1½ inches, eight may be wound, etc. For this reason the winding apparatus is termed a "multiple" machine. The older machines simply wound on the copper and silk, depending on the operator to slip in the sheets of paper at the proper intervals. The new machines, called "multiple automatics," insert sheets of paper between the layers without attendance on the part of the operators, the strip of paper being automatically cut off each time a little wider than before, so as to cover the increased diameter.



The next operation after the coils are wound is to saw them apart. A considerable space of paper is left without wire between adjacent coils on the rod so that when they are sawed apart, the ends of the layers cannot escape from the paper and unravel. The inner end of the wire is then fished out by means of a crochet needle and both ends are stranded with a tinned copper wire to give strength, stiffness and ease of soldering. The whole coil is then wrapped in a paper jacket with fringed ends, which are folded down over the ends of the coil and the latter is ready for shipment.

Each of the new automatic machines is capable of winding 1200 to 1500 coils per day with 10,000 turns each. An idea of what this means can be gained from the fact that an operator can only wind about 60 such coils per day by hand. One of the winding machines will consume 500 lbs. of No. 36 wire per day, while a wire-covering machine will only cover about one pound per day per head. The company now has 14 of these multiple automatic winding machines, and has 30 more under way.

The automatic winding machines are very accurate in that, provided the gage of the wire remains uniform, the resistance of coils turned out does not vary more than one-fourth of one per cent; one-half of one per cent is guaranteed when wanted.

A few facts concerning the raw materials used may be of interest. The greater part of the company's work consists of telephone drop and other coils of high resistance for modern bridging systems. These coils are wound with a copper wire running down as fine as .003 of an inch in diameter, which is somewhat finer than No. 40 B. & S. gage. With copper running from No. 36 to the finest gage used, the silk thread runs 120 miles to the pound. This thread contains much less silk than would be required to wrap each individual turn, so that the total cost of the coil complete is less than the cost of single-covered silk wire of equivalent length required for a similar coil. The paper used is imported parchment, .0008 inch in thickness, stiff, tough and strong, and with considerable insulation resistance. The use of this material allows, it is claimed, from 4 to 16 per cent more turns to be wound into the same space as would be occupied by a single-covered silk wire of the same gage. The strips of paper take out any little irregularities and prevent any turn of the wire, especially those on the end of the layers, from working down past the other layers and coming into the neighborhood of turns with a considerably different potential. This adapts the winding to high-tension work, such as that of induction coils.

The company not only does the winding, but makes also its own winding machines in a machine shop in the same building. It also covers its own wire for use on

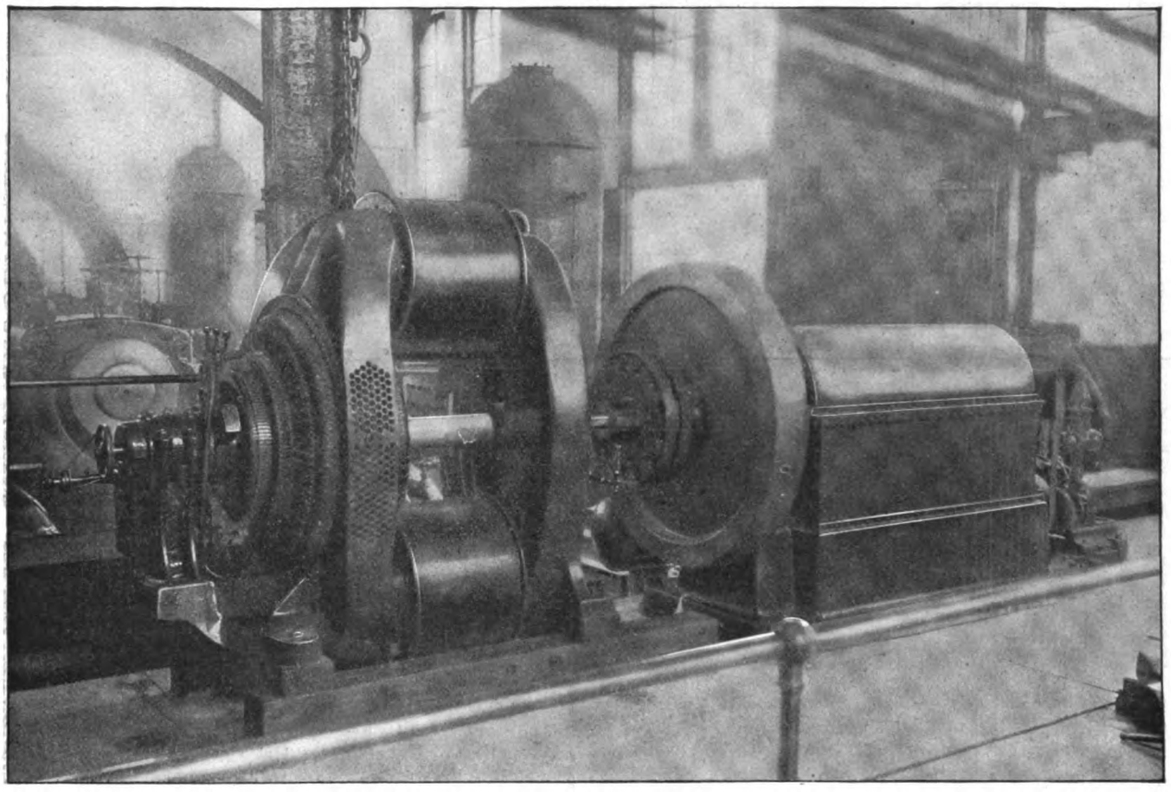
A STEAM-DRIVEN WATER-POWER ELECTRIC PLANT. VIEW OF GOVERNOR.

Digitized by Google

induction coils. The company has also been compelled, in order to get uniform gage, to draw its own copper. It has a drawing plant at Belleville, N. J., which now turns out 1500 lbs. per week of No. 35 wire. Eight thousand pounds of wire of various sizes are also absorbed per week from other sources. The number of employees at present is 128, and the machines run five nights per week.

## A STEAM-DRIVEN WATER-POWER ELECTRIC PLANT.

There is at present in operation in the pumping station of the City of Columbus, Ohio, a lighting plant which is unique in character, and which presents a number of interesting engineering features.



The Director of Public Improvements, finding that the pumping capacity of the station was greater than required, looked about for some means of utilizing the surplus capacity, and hit upon the idea of using the surplus water that the pumps were capable of supplying, to drive water wheels direct coupled to series arc dynamos.

The specifications were very rigid in their requirements with regard to both efficiency at all loads and to speed governing under sudden and great changes of load. The difficulty of the problem was also enhanced by reason of the very limited space available for the machines and piping, and by the high speed required for direct connection to the Western Electric Company's 100-light arc dynamo, which was the machine selected by the engineer in charge. This speed, 650 r. p. m., necessitated the use of impulse wheels only 18 inches in diameter, and in order to obtain 110 h. p. from each unit 18 nozzles were required. These were arranged with 6 runners, 3 nozzles to each runner, since a larger number of nozzles per runner would have reduced the efficiency below the guarantee.

The use of contracting nozzles to keep up the efficiency at light loads was prohibited by the great cost and complication of so large a number of contracting nozzles. Ordinary butterfly valves were accordingly used with the cam mechanism for operating these valves shown on the last page, arranged to actuate them one after the other, instead of all together, as had previously been common practice. As a result of this arrangement, all the valves in operation, except one, would be wide open and working, therefore, at their maximum efficiency, and thus the low efficiency of a partly closed butterfly valve would have an almost inappreciable effect in lowering the total jet efficiency of the machine, and at six values of the load, when a valve had just completely closed, would have no such effect at all.

The rigid requirements with regard to efficiency having been thus complied with, the problem of speed governing was next attacked. The small diameter of the runners, rendered necessary by the high speed so far reduced their momentum that it was necessary to add a heavy fly wheel in order to keep the variations of speed within the guaranteed limits. The high speed also prohibited the use of the ordinary cast-iron fly wheel. The wheel was accordingly made with a steel rim shrunk on to a cast-iron web. The governor is the ordinary mechanical relay actuating six cams as shown in the illustration on the opposite page, the connection between the cam shaft and the governor being by gear and pinion.

The water chambers were cast in two pieces, as shown below, the nozzles being bolted on so as to come in exactly the right position with reference to the runners. This large casting rested on the cast-iron base and was bolted to it. The casing was made of riveted boiler iron in two parts, the upper half being provided with eyebolts for lifting. The details of the piping, receiver, etc., are clearly enough shown in the accompanying illustrations.

IMPULSE WHEELS DIRECT COUPLED TO ARC MACHINE AT THE WATER WORKS PUMPING STATION OF COLUMBUS, OHIO.

The fact that this plant has now been running for over 12 months without trouble and to the satisfaction of the engineer in charge, reflects credit upon the American Impulse Water Wheel Company, which was the builder and contractor, as well as upon this company's consulting engineer, Mr. Thorburn Reid, to whom was entrusted the task of meeting the difficulties presented by this new departure in water-wheel engineering.

### LOCKE INSULATORS.

In the manufacture of insulators for very high voltages the material used must not only have a very high specific resistance and dielectric strength to resist the tendency of the current to break through it, but it must interpose a large creeping distance to prevent the current traveling over it and must provide a considerable gap between the edge of the bell and the pin to prevent the current sparking across from the wet exterior to the pin and charring and setting fire to the latter. These various considerations, combined with the peculiarities of china, porcelain and glass making, constitute the construction of insulators a fine art. The ways in which some of the difficulties of the problem have been overcome by one maker are illustrated by the accompanying reproductions, Fig. 1, of several styles of insulators made by Mr. Fred M. Locke, Victor, N. Y.

In the first place the insulator, when used for heavy work, at least, is mounted on a steel pin such as is shown in the lower right-hand corner of the illustration, and the upper part of this pin is capped with wood to prevent the breakage of the insulator through the difference between the expansion of iron and the material used in the bell. Below the wood is a porcelain sleeve which surrounds the pin and rests upon the top of the cross arm. This porcelain acts as a protection against sparking from the shell of the insulator to the pin and greatly increases the sparking voltage. The use of this pin may be seen in the other illustrations of the lower row. That to the extreme left is a transposition insulator, while to the right of it are shown porcelain and glass insulators for various voltages.

In the upper row are shown various forms for street railway use. Some of these are made in two parts, which are burned together in the second heat when the glaze is put on. This gives an extra resisting wall, which must be broken down before the current can leak through, besides which this form of construction makes each part of a more uniform thickness during the first heat, when the different rates of shrinkage of parts of different thicknesses would tend seriously to set up serious initial strains which would greatly weaken the resisting powers of the insulators to the strains of service.

Pony porcelain insulator with one petticoat for telephone lines. | Pony double-petticoat china insulator. | Street Railway top groove cable insulator, two parts. | Street Railway porcelain insulator side groove for standard pin. | Street Railway cable china insulator for heavy work.

Porcelain transposition insulator. | Glass insulator for 5,000-volt lines. | Glass insulator for 20,000-volt lines. | Porcelain and glass insulators for 25,000-volt lines. | Pin for street railway and heavy line work.

FIG. 1.—VIEWS OF VARIOUS FORMS OF LOCKE INSULATORS.

### THE PULLEN BATTERY.

Not to be outdone by its younger brother the dry battery which has recently been adapted to recharging, and consequently to storage work, the wet battery has been improved in the same way.

In the Pullen cell, which enjoys this distinction, the electrolyte is 10% sulphuric acid and the positive electrode is carbon in the form of a cylindrical rod like an ordinary arc light carbon. This is surrounded by a thick layer of a black mass, which is used as a depolarizer, but which differs from that used in the usual Leclanche or the dry cells. The negative electrode is a zinc cylinder surrounding the carbon electrode.

The strong activity of the depolarizer was shown to us by the inventor in an interesting experiment. He made an improvised cell by touching the end of a carbon and zinc rod, each ½ inch in diameter, to the opposite sides of a cloth saturated with dilute sulphuric acid and closed the circuit by an electric bell; the action was too weak to ring the bell, but as soon as he added a little of the depolarizer between the carbon rod and the cloth the bell began to ring at once and did not stop until the sulphuric acid was consumed; the formation of sulphate of zinc could be seen. If, then, some fresh elec-

Digitized by Google

trolyte was added, the bell began to ring again.

The e. m. f. of the Pullen cell at open circuit is given at 2.2 volts, and the internal resistance is said to be very small. The cell can be used to advantage for electric bells, fans and all such purposes, just as can other primary cells. The main point of interest, however, is that it is said to compete successfully with accumulators in automobile traction. The inventor states that the cell may be discharged at a very high rate without being injured and that it can be recharged again by simply connecting it with the mains of an electric station, in the same way as is done with accumulator batteries. The inventor points out that no lead at all is used in his cell, and that it is therefore possible to construct it exceedingly light compared with lead accumulators; so that his cell has the advantage of the accumulator batteries for driving automobiles, without the disadvantage of the heavy weight of the latter.

The complete weight of a battery of 44 Pullen cells, ready for use on automobiles, is given at 300 lbs.; this is said to be sufficient to drive an automobile with two people over 35 miles with one charge, the complete weight of the automobile with the battery, but without passengers, being 1100 lbs. A crude test of one of the very small cells, weighing complete in a glass jar 16 oz., is said to show a pressure on open circuit of 2.04 volts and a current on short circuit as much as 15½ amperes, which after about 20 minutes of short circuit fell to 1½ amperes. This is an exceptionally large current for such a small cell. The energy to be obtained from a Pullen battery is shown by the statement that one h.p. hour is available for every 50 lbs. of complete battery, if discharged in 6 hours.

FIG. 3.—A PULLEN CELL.

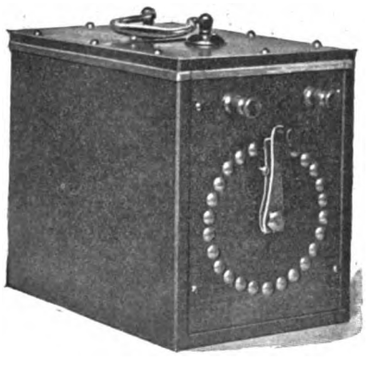

FIG. 4.—A CAUTERY OUTFIT OF PULLEN BATTERIES.

The Pullen Battery & Electrical Manufacturing Company, Philadelphia, was incorporated in 1897, to exploit the patents of Leon W. Pullen. The officers of the company are Dr. Wm. A. Davis, President; Louis W. Pullen, Vice-President; J. Madison Pullen, Secretary; Dr. S. Lewis Ziegler, Treasurer. The board of directors consists of the above named, together with Jas. F. Davis and Albert E. Bainbridge.

### A MARINE GENERATING SET TYPICAL OF RECENT DEVELOPMENTS.

The requirements of marine work are most difficult to fill. Not only is space economized to the last degree but into this curtailed space must be built a machine which will have unusual capacity when speed and weight are considered.

The combination illustrated in Fig. 5 consists of a Bullock Type "N-I" generator direct connected to a Forbes marine engine.

The engine cylinder is 5 ins. x 5 ins., and is made for the high pressure of modern marine practice. The cylinder is supported upon three hollow steel legs which are rigidly fastened to a subbase common to both engine and generator. To two of these supports the cross-head guide is securely bolted. Means are provided to adjust for wear of the cross-head shoe and guide and in the main bearings. A perfect system of sight-feed lubricators is installed upon the side of the cylinder with copper tubes leading to all of the wearing surfaces of the engine.

A small balance wheel is provided and assists in the regulation of the engine speed. The governor, which is installed on the outer end of the shaft, is of the inertia-centrifugal type and maintains a speed between no load and all load limits of less than two per cent variation. The valve is of the cylindrical balanced type and gives a perfect steam distribution.

The generator, like the engine, is very compact, pleasing in outline and presents some excellent features of mechanical and electrical design as will be seen by consulting the sectional engraving, Fig. 6.

The yoke is a steel casting of the conventional circular form having inwardly projecting pole pieces of laminated soft steel. Each pole is bolted to the frame by two bolts, A-A, the centrally located rivet, B, of the laminated pole, C, being tapped and serving as a nut for the bolts.

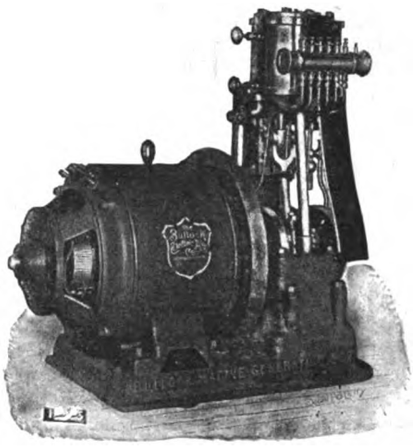

FIG. 5.—BULLOCK MARINE GENERATING SET.

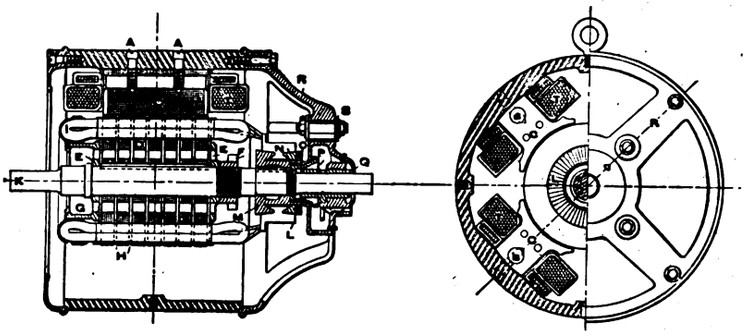

FIG. 6.—SECTIONS OF BULLOCK MARINE GENERATOR.

The armature core, D, is built up of laminated soft steel mounted directly upon the shaft and held firmly together by iron end plates, E, and nuts, F, as shown, one end plate resting against the shoulder, G. Ventilating slots, H, perpendicular to the shaft, provide a perfect means of ventilation. The windings, I, are machine formed and hot pressed and are highly insulated before being placed in the slots of the core. The windings are held in place by steel wire bands wound in slots, making a flush finish with the outside of the laminated core. The armature shaft rests in a phosphor-bronze bearing of liberal dimensions at the outer end and is key-seated in the hub of the engine flywheel, which is of extra width and provided for receiving the end, K. The commutator bars, shown at L, are held together by sleeve, M, ring, N, and nut, O. Oil shield, P, prevents oil from finding its way from bearing, Q, into the armature.

The bearing, Q, is of the self-oiling type, as shown. The end housing, R, securely bolted to the frame, carries the

Digitized by Google

brush studs, S. The field coils, T, are machine wound and thoroughly insulated, and are slipped over the poles before the latter are bolted in position.

The engine operates at 600 r. p. m. and at this speed the capacity of the generator is 5 kw. at 115 volts pressure.

This particular set is now installed upon the steamer "Aberdeen," a vessel recently built for the Pacific coast trade.

The manufacturers, the Bullock Electric Manufacturing Co., Cincinnati, Ohio, will be pleased to send Bulletin No. 0434 showing other engine type generators, to those requesting it.

---

THE LUNDELL SPLIT-POLE DYNAMO.

Several designs of dynamos have been brought out on the American market in which special provision has been made to automatically overcome the armature cross-magnetization and thus prevent the armature from distorting the fields and shifting the plane of commutation under load to a position different from that under no load. In most dynamos, however, no special provision is made, and the effect is only minimized by saturating the poles and providing a wide air gap, both of which features increase the cost and reduce slightly the efficiency of the machine. In a machine recently put on the market by the Sprague Electric Company, New York City, there is embodied an original and elegant design of Mr. Robert Lundell for overcoming this difficulty. In this design the field distortion is automatically corrected by means of the usual series coil and a very simple modification of the usual form of pole piece. The principle of its operation may be explained by reference to Fig. 7, which is a diagrammatic cross-section of a machine built on what is known as the "split-pole principle."

A is the armature rotating as shown by the arrow, and the field is, as usual, fitted with laminated poles bolted to the yokes. The polar laminations carry one wide projecting horn on the side toward which the armature rotates, and are slotted down the middle almost to the air gap. The purpose and result of this construction are as follows: When the machine is running under no load its magnetic circuit is excited to a density very near saturation. Under this condition the section, b, of the pole to one side of the deep slot is magnetized to a greater density than the section, a, at the other side of the slot, since the reluctance through the path, b, is less, due to the greater area of the air gap across which the lines through this section, b, must pass. At no load, therefore, the section, b, is practically saturated, while a is considerably below saturation. As the load increases the ampere turns, due to the series coils on the compound-wound field, increase the excitation of the whole field. This increased force drives more lines through the field circuit, but b being already saturated and a unsaturated, these lines take the latter path; thus the increase of magnetism, due to increased load, is forced over to the left, where it counteracts the general shifting of the polar magnetism to the right caused by the armature distortion.

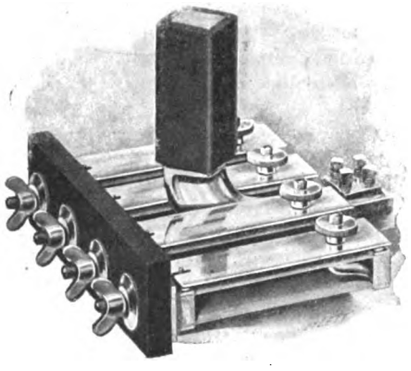

FIG. 8.—DETAIL OF BRUSH HOLDER

It is thus clear that the method is due solely to the increase of the field strength with increased load and is, therefore, dependent upon over compounding.

Another interesting detail of the same machines is the brush holder, a view of which is shown in Fig. 8. The brushes are carbon and are clamped to holders mounted on parallel motion springs through which current is carried to the cross connections. The arrangement utilizes the whole surface of the commutator, since the carbons butt against each other. This gives a better distributed wear upon the surface of the commutator and prevents the development of ridges. The clamps are made light to prevent jumping of the carbons. The parallel motion maintains parallelism between the face of the carbons and that of the commutator if the latter rises and falls, and the arrangement is such that the machines will run in one direction as well as the other.

### A LEAD ZINC STORAGE BATTERY.

The use of dynamo currents is becoming so general that a convenient form of small storage cell could often be, with advantage, used in place of Leclanche or dry cells commonly used for open circuit work. This storage cell could be connected in series with incandescent lamps for occasionally recharging, which would cost much less than the replacement of dry cells when discharged, or the renewal of the zinc or salammoniac of the ordinary wet battery. The United States Battery Company, New York City, puts on the market a type of cell particularly adapted for such use, the appearance of which is indicated in Fig. 10.

This is a lead zinc cell using dilute sulphuric acid as the electrolyte, the acid forming sulphate of zinc and depositing lead during discharge and forming sulphate of lead and depositing zinc during charge. An idea of the capacity of this battery can be gained from the fact that the cell shown, which is three inches in diameter by five inches in height, and weighs two pounds, has a capacity of 10 ampere hours at a half ampere discharge rate and a safe maximum discharge rate of one ampere. Its pressure on open circuits is 2½ volts, and on closed 2.35 volts.

One of these cells has been under test to determine its life and the necessity of renewals, and the company claims it has been charged and discharged 38 times and is still in service without any renewal of the materials or electrolyte.

In construction the cell consists of a glass jar with a sheet of zinc bent into cylindrical form immediately inside the

FIG. 10.—A LEAD ZINC CELL.

glass and a central lead electrode. The top is provided with a vent for escaping gases. The new form which the company is about to put on the market is made with a removable top and uncovered glass so that the appearance of the inside can be seen and the condition of the cell indicated at all times.

The battery is carried in stock with the liquid separated from the electrodes, so that there is no deterioration on the shelf.

### A TOY AUTOMOBILE.

Realizing that the present popularity of automobiles would extend to the children the Knapp Electrical & Novelty Company, New York City, has put on the market a miniature automobile for the Christmas trade in toys. The small machine weighs boxed 10 lbs., and is about 1 ft. in length and 6 ins. wide by 7 ins. high. It is driven by two dry cells, 6x2½ ins. in size, slipped under the dos-a-dos seats. The motor drives the rear wheels through double reduction gears. The battery will drive the

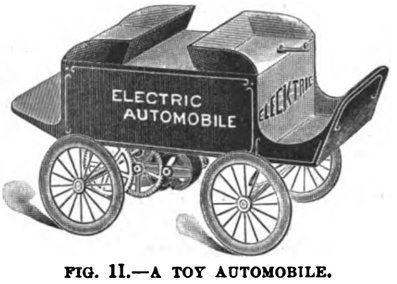

FIG. 11.—A TOY AUTOMOBILE.

wagon continuously about five hours, and if used intermittently, from 15 to 20 hours.

### AN ANNUNCIATOR MECHANISM.

In the design and construction of annunciators the prices which can be realized necessitate that all metal parts shall be simple punchings or stampings and that they be readily assembled and require no great amount of adjustment. To get up an annunciator under these limitations that will not stick or bind, or fail to reset, and that will remain in working order for years without attention, is a problem requiring the exercise of considerable ingenuity.

Fig. 12 shows an annunciator recently brought out by the Star Electric Company, Binghamton, N. Y., designed to meet these conditions. As may be seen from the figure, the armature, A, consists simply of a rectangular piece of sheet iron with two holes, which are slipped over the prongs, P, shoulders on which serve as pivots. This armature is held away from the magnet cores by the hook-shaped spring, S, of sheet brass, and holds the indicator shaft by engaging the heel, H, of the lever, L. When the armature is drawn down by the magnets this lever falls, due to the weight, W, after which it is reset as usual by the arm, B, on the restoring shaft.

The advantages of this construction are several. The armature being suspended at its center of gravity, is not likely to be thrown by any mechanical shock or jar. The spring being of the flat type, and having a very slight motion, does not require readjustment, and will not break or weaken even after long and severe use. In the event of any armature sticking to the magnet when the drop is operated, the projecting toe, T, strikes the right-hand side of the armature when the drop is reset and restores the armature to its proper position. When any drop is reset, the in-

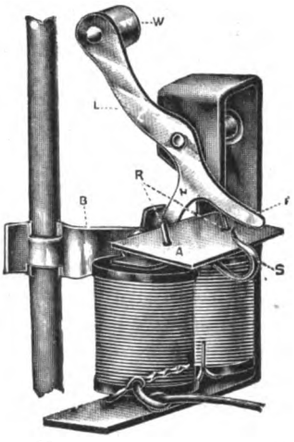

FIG. 12.—AN ANNUNCIATOR DROP.

dicator shafts of all the other drops are slightly disturbed, thereby keeping them free in their bearings. All iron parts are copper-plated to prevent corrosion.

The bell is mounted on the front cover, so that, by removing the screws fastening this to the sides of the case, the bell may be readily removed for adjustment or repairs.

This type of annunciator is termed by the makers "Style E."

### A DIRECT READING POWER GAGE.

The measurement of the power given by the steam to the piston of a steam engine has always been an elaborate operation and rarely a satisfactory one, involving as it does the manipulation of delicate apparatus under trying circumstances, subsequent careful measurements with a planimeter and calculations from the figures obtained. While apparatus for this purpose has been brought to a high stage of perfection the difficulty and trouble experienced by the ordinary engineer in taking cards, measuring them and calculating the results, together with the fact that on varying loads these cards do not give average results, render the indicator an instrument for fine analytical work, rather than the every-day measurement of power developed. The power gage described below is intended to give at all times an indication of the power being developed in the cylinder as easily read as the steam gage or the switchboard instruments.

The principle upon which this instrument operates is the driving of a miniature turbine by jets of steam from the cylinder ends and measuring by means of a simple form of tachometer the speed of this turbine. Two pipes run to the instrument respectively from the two ends of the cylinder of the engine, the power of which is to be measured. Each pipe terminates at its upper end in two small nozzles which direct jets of steam upon the buckets of a small steam turbine imme-

Digitized by Google

diately over them. This turbine drives a retarding device consisting of an air fan running in an enclosed chamber, in which there is also a non-rotating fan. This latter fan is mounted on a shaft with a retractile spring, and carrying also an indicating needle. As the turbine rotates, the movement of the air set up by the fan which it drives drags around the indicating fan. This drag is balanced by the retractile spring and measured on the indicating dial. The torque is dependent upon the velocity of the turbine, which in turn is dependent upon the time average of the pressure of the steam jets, so that the indication is a measurement of this pressure. The turbine has sufficient mass to give a fly-wheel effect which maintains an approximately constant speed under the intermittent impulses of the jets.

Each entering pipe from the steam cylinder has two nozzles se. to drive the turbine in opposite directions. One of these nozzles is opened during the forward stroke and the other during the return stroke of the piston by means of a small shutter thrown over by a tappet motion operated from the crosshead just at the instant when the crank reaches the dead center. The shutters are so arranged that the back pressure and compression during the return stroke of the piston operate on the jet tending to retard the motion of the turbine set up by the forward pressure in the other end of the cylinder. Thus the turbine gets a resultant forward pressure proportional to the average pressure on both sides of the piston.

The uses of an instrument of this kind are numerous, among them the following: An indication of bad valve adjustment; an indication of the friction load every time the engine is started; from which the general condition of the plant may be ascertained; an indication of the division of the load between the cylinders of compound or triple-expansion engines; an indication of the relative amount of work done in each end of the cylinder; this can be obtained by simply turning the cocks at the two ends alternately; an indication of the stability of governing, if a governor "hunts" or "see-saws" the power developed in the cylinder will fluctuate rapidly; and a means of determining whether any unusual losses shown between the coal pile and the switchboard are on the steam or the electrical side of the engine cylinder.

This instrument is the invention of Mr. G. F. Atwood, and is being placed upon the market by the Atwood Power & Speed Gage Company, New York City.

THE MIETZ & WEISS KEROSENE ENGINE.

For the driving of electrical generators requiring close regulation an internal combustion engine which delivers one impulse per revolution is naturally better suited than is the ordinary type of gas engine which gives one impulse during two complete revolutions. An engine of the two-stroke cycle type, as it is called, made by August Mietz of New York City, is shown in Fig. 13, coupled to a Lundell generator. The means of obtaining one explosion per revolution are as follows:

The crank case is enclosed and every time the piston makes an outward stroke the air within the crank case is compressed to about three pounds per square inch. At the end of the outward stroke the piston uncovers an exhaust port in the lower side of the cylinder and also an admission port in the upper side of the cylinder, through which the air compressed in the crank chamber rushes and drives the burned gases out through the exhaust port. On the return stroke of the piston the ports are first closed, the fresh air in the cylinder is compressed, a suitable amount of oil is pumped in and the mixture is ignited at the end of the stroke. The explosion and expansion follow until the piston reaches the outer end of the stroke, uncovering the ports and allowing the burned gases to exhaust, after which the cycle repeats itself once per revolution.

The engine may be said to have no valves, or, rather, the piston becomes its own admission and exhaust valve.

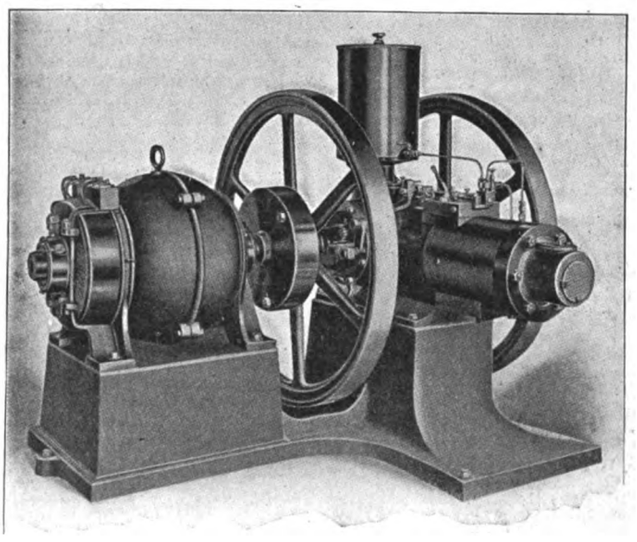

FIG. 13.—A TWO-STROKE CYCLE OIL ENGINE DIRECT COUPLED TO A GENERATOR.

The governing is effected on the "hit or miss" principle by simply missing strokes of the oil pump and thereby failing to deliver oil to the cylinder during one revolution. The air compression and expansion go on during idle strokes just as they do during working strokes. The governor itself is most simple in character, as it contains no springs nor weights whatever. It simply consists of an oscillating weight driven by an eccentric back and forth over an inclined surface on which it rests, but from which it is free to rise. Normally when this piece is driven forward by the eccentric it engages the stem of the oil pump and pumps a charge of oil to the cylinder. The inclined plane stops a little short of the position at which the oscillating piece or pusher engages the pump stem so that this piece rides over on to a level surface. If the speed rises above normal the pusher does not ride over on to the horizontal surface, but continues, due to its own inertia, up into the air in the direction of the inclined plane, thus missing the pump stem and failing to deliver oil to the cylinder. As soon as the speed falls to normal the oscillating piece again follows the path to which it is held by gravity and again engages the pump stem and delivers fuel to the engine.

The engine is started with a hot igniter, but the external heat for this may be turned off after the engine is once started, the compression being sufficient with the temperature at which the igniter remains to ignite the gases at the proper instant. The engine is fitted with a very simple lubricating system, the oil being drawn into the points to be lubricated from a tank on the side of the engine and through sight-feed oil cups simply by means of the intermittent suction set up in the crank case. The oil is supplied in this way to two points; one the piston and the other the connecting rod from which it passes to the crank pin. The main bearings are lubricated by ordinary ring oilers.

The flexible coupling shown in the illustration consists of three studs on the engine fly wheel and three on the generator disc. These studs are connected together in pairs by rubber links or bands, which stretch considerably and take up any slight irregularity in the motion of the engine.

## NEW BOOKS.

The Columbia Engineer. New York: The Engineering Society of Columbia University; 144 pages, illustrated. Price, $1.00.

The annual publication of the Engineering Society of Columbia University, containing the lectures delivered before this society, with complete illustrations, is a student annual intended chiefly for the members of the society. Owing to the increasing call for the volume from others of the engineering profession it has been considered advisable to place the book on sale at the price given above.

Digitized by Google

A Dividend to Labor. By N. P. Gilman. Boston: Houghton, Mifflin & Company. 400 pages. Price, $1.50.

While it is not the custom to review in these columns works which are not of an engineering or electrical character, this book is of such great interest to employers of labor that it deserves notice here. Mr. Gilman is a well-known authority on this subject, being the author of a previous work entitled "Profit Sharing Between Employer and Employee." His latest work is intended to be a study of profit-sharing and similar institutions in which part of the profits are appropriated for the benefit of the employees. Five cases of profit sharing are described in detail. Among them are the Bourne cotton mills of Fall River, Mass., the establishment of the Procter & Gamble Company, Cincinnati, Ohio, and the Nelson Manufacturing Company, Leclaire, Ill.

## LEGAL NOTES.

BENJAMIN A. GOULD VS. THE EDISON ELECTRIC ILLUMINATING COMPANY OF NEW YORK.—An interesting case concerning the rights of the central station to make a minimum charge was the subject of an opinion handed down by Judge Beekman of the New York Supreme Court, October 24, 1899. The suit was brought to compel the Edison Company to re-connect the premises of the plaintiff. Damages to the extent of $500 were also demanded for the refusal of the company to comply with the plaintiff's demand after the plaintiff had refused to meet the minimum payment of $1.50 per month when the charges for current consumed fell below that sum. The opinion held that the charge was a reasonable and justifiable one, since it was claimed by the defense that each new lamp connected to the system required an additional outlay in the generating and distributing plant of $20. Since the number of lamps connected for the plaintiff was 11, the additional investment necessary to supply these lamps at any time they might be wanted amounted to $220. Judgment was accordingly ordered in favor of the defendant.

## PERSONALS.

MR. CHARLES T. CHILD, technical editor of the "Electrical Review," was married on November 30th to Miss Bertha May Cushing of Malden, Mass.

MR. H. J. RIFFEL, who, until recently, was connected with the Siemens & Halske Company, has severed his connection with that concern to join the staff of the Belknap Motor Company of Portland, Maine.

MR. C. S. KNIGHT has resigned from his position as Vice-President and General Manager of the Siemens & Halske Electric Company of America and will be succeeded by Mr. O. S. Lyford, Jr., formerly chief engineer of the Westinghouse Electric & Manufacturing Company, and since electrical engineer of the Siemens & Halske Company. Mr. Knight will take up other work for the Whitney Syndicate in the East.

Mr. W. W. BURNHAM, for fifteen years or more connected with The Electric Gas Lighting Company of Boston, and for four years manager of that company, has recently associated himself with the firm of Messrs. Stanley & Patterson, New York, dealers in electrical supplies. Mr. Burnham will have general charge of their correspondence. His experience and acquaintance with the electrical trade should prove of service to him in anticipating the wants of his old friends and customers.

MR. RUSSELL THOMAS KINGSFORD, who was for several years chief engineer of the American Impulse Wheel Company, has resigned that position and is now chief engineer of the Rushmore Dynamo Works of Jersey City. Mr. Kingsford is a graduate of Stevens Institute of Technology and has had extensive experience in designing dynamo machinery. He will assume entire charge of the building of the new line of large multi-circuit arc machines, relieving Mr. Rushmore, who will now give his attention largely to developing his rapidly increasing searchlight and optical business.

## TRADE PUBLICATIONS.

THE FALCON ELECTRIC MANUFACTURING COMPANY, New York City, has published bulletin No. 1 on "Falcon All-Drawn Pure Copper Knife Switches."

THE ELECTRIC APPLIANCE COMPANY, Chicago, has issued a pamphlet giving a description and prices of the Gutmann recording wattmeter, for which the company acts as Western selling agent.

THE REEVES MACHINE COMPANY, Trenton, N. J., has published a small pamphlet on the subject of "Harthan's Metallic Rod Packing" which the company is now making for service on piston rods, valve rods, etc.

THE WESTERN ELECTRIC COMPANY'S latest bulletin is on the subject of "New Type Sunbeam Incandescent Lamps" and calls particular attention to the lamp of this make designed for railway work. These lamps are also described in a new catalogue, No. 1-S.

THE MANHATTAN ELECTRICAL SUPPLY COMPANY, New York City, has published a new general illustrated catalogue No. 7 on electric light, household, telephone and telegraph electrical supplies. The catalogue is a very comprehensive one, running up to 352 pages.

THE PAYNE COMPANY, Elmira, N. Y., has brought out a new catalogue on the Payne high-speed automatic engine. The catalogue is illustrated throughout by views of engines direct coupled to electrical generating sets. The catalogue gives detailed drawings of several special points in the Payne engines, such as the valve and the crosshead.

THE STERLING VARNISH COMPANY, Pittsburgh, Pa., has published a booklet of testimonials, each page consisting of a reproduction of a letter of recommendation of Sterling varnish from some maker or user of electrical machinery. There are some 70 of these pages, many of them coming from the largest and best known concerns. The book is also being printed in French and German editions for distribution abroad.

THE MURRAY IRON WORKS COMPANY, Burlington, Iowa, is circulating a new catalogue of the Sioux Corliss engines. The catalogue illustrates and explains with clearness the various forms of this make of engine and the meritorious details, such as the improved form of girder frame, the high-speed ball-bearing governor, the insulation of the exhaust passages from the cylinder, the improved valve motion and dash pots and several other valuable points.

THE SPRAGUE ELECTRIC COMPANY, New York City, has brought out catalogue No. 75, entitled "Interior Conduit," covering the various styles of conduits made by this company, viz., iron-armored, brass-armored, unarmored, and flexible metallic, with insulated fitting boxes, elbows, couplings, etc. The catalogue is a most complete one of 148 pages and gives a great deal of valuable information on the subject of interior wiring in conduits. All wiring contractors will find it valuable for this information if for no other reason.

MR. JAMES G. BIDDLE, Philadelphia, has created quite a stir among college professors and electrical engineers by issuing circular No. 315, entitled "New Apparatus at Special Prices." It describes a considerable number of high-grade electrical measuring instruments as well as psychological apparatus, which, for reasons explained in the pamphlet, are offered for sale at remarkably low prices. These figures would be impossible under other circumstances, and are especially noticeable now when the tendency of prices is upward.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS, Scranton, Pa., have started another regular publication entitled "The Official Messenger." This periodical is issued for free distribution among employees, and is intended to serve as a medium of communication between the home office and the force of men in the field. The initial number is devoted to a detailed description of the work and equipment of the schools, with photographs of heads of departments, instructors, etc., and views of the buildings, offices, press rooms, etc.

THE BOSSERT ELECTRIC CONSTRUCTION COMPANY, Utica, N. Y., has brought out two new descriptive catalogues, one on panel boards and the other on the Bossert plugged-steel outlet boxes and Erickson conduit insulators. The Bossert Company has standardized a line of panel boards sufficiently comprehensive to supply all ordinary demands. The company also makes, in addition to its steel outlet boxes and steel boxes for panel boards, a line of cast-iron boxes for all styles of General Electric cutouts and is even extending its output of general fixture boxes so far as to include boxes for mine or underground work.

THE ELECTRIC STORAGE BATTERY COMPANY has published circular No. 55 under date of Oct. 1, 1899, entitled "The Application of Storage Batteries in Railway and Power Plants," being a reprint of the paper by Mr. Herbert Lloyd in the electric railway number of "Cassier's Magazine." This bulletin gives useful data, one special piece being a curve of voltages of a cell under rapidly recurring charges and discharges. The bulletin also describes several well-known storage battery sub-stations, such as those of the Buffalo Railway, the Metropolitan Railway of New York City and the South Side Elevated Railway of Chicago.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has brought out during the past month two notable additions to its line of handsomely illustrated descriptive pamphlets, one on "Westinghouse Railway Motors" and the other on "The Westinghouse Electro-Pneumatic System for Controlling Railway Motors." The electro-pneumatic system is virtually what is commonly called a "multiple-unit system," whereby scattered motors throughout a train of motor cars may be all controlled simultaneously from any desired platform. The controlling apparatus is pneumatic in character, being worked by the compressed air of the air-brake system. The controlling and braking system are interlocked so that the brakes cannot be applied while the power is on nor the power applied while the brakes are on.

THE WESTERN ELECTRIC COMPANY publishes a convenience for central stations in the shape of what is called "The Meter Record Book." This consists of a book of

Digitized by Google

blanks, each a fac simile of the dials of an integrating wattmeter. There are 250 of these blanks in a book, perforated so that they may be readily torn out and numbered successively. Four books constitute a set and the blanks of these four are numbered consecutively from 1 to 1000. The book is used by the meter man on his rounds. With a lead pencil he marks the fac simile of the dial so as to show the exact position of the hands on the meter face. The form is returned to the office, proper extensions are made, and the slip is filed for reference. The record book is capable of other useful applications. The man who reads the meter may tear out a slip and leave it with the consumer to give a record by which the latter may compare his bill.

THE SKINNER ENGINE COMPANY, Erie, Pa., has published a catalogue covering its new system of automatic lubrication. The system consists of a pump delivering the oil from the supply tank to an overhead reservoir from which it flows by gravity to the points to be lubricated. The pump is driven by the valve rocker. The oil is fed to the crosshead guides and shaft boxes by means of hinged feeder pipes which can be turned back to provide ready access to the parts below them. These feeders contain regulating screws by means of which any desired number of drops can be maintained through sight-feed glasses placed below them. When these feeders are thrown back the supply is cut off. The oil passes from the bearings to an oil and water separator, from which the separated oil returns to the reservoir, which, in turn, contains a purifier containing no filtering material nor anything that requires renewal, but effecting, it is claimed, a perfect purification.

"THE VICTOR TELEPHONE JOURNAL" is the name of a new publication devoted to independent telephone interests, and particularly to the advancement of the business of the publisher, the Victor Telephone Manufacturing Company of Chicago. The editor of the new publication is Mr. Wm. T. Blaine, President and General Manager of the Victor Company. Vol. I., No. 1, which is dated October, 1899, states that "The Victor Telephone Journal" will appear "every little while, as improvements, the accumulation of interesting information, and other conditions make it desirable. This will probably be once a month." The paper takes no advertising and has no subscription rates—i.e., it is sent free to those who feel sufficiently interested to send their names. The first number warrants much more than this effort on the part of subscribers, as it contains, in addition to information about Victor telephone apparatus, some valuable instructions concerning the equipment of party lines for toll service wired on the bridging system, and with switching stations between divisions.

THE SIMPLEX ELECTRICAL COMPANY, Cambridgeport, Mass., has brought out two descriptive catalogues, one on rheostats made up on the "unit" system, and the other on electric car heating on the "American" system. The "unit" system rheostats are now made up in the form of motor controllers with automatic release, as well as a form of theatre dimmers. An entirely new type of car heater has been developed, known as the "enamel" car heaters. They consist of cast-iron plates on one side of which the resistance wires are embedded as in enamel rheostats. The cast-iron surface is not covered by any casing or netting, but is opened direct to the air of the car. On account of the large surface for radiation which can be obtained in this way as compared with that of coiled spring types, a lower temperature heater can be utilized, giving a larger amount of air heated moderately than is possible with other types. This heater is advocated particularly for elevated railroad cars. A hose may be used for cleaning the car without fear of injury to the heaters.

## BUSINESS NEWS.

MORSE, WILLIAMS & CO., Philadelphia, Pa., the elevator manufacturers, have removed their offices to the twelfth floor of the West End Trust Building. Their factory address, however, will remain the same.

THE ELECTRIC APPLIANCE COMPANY, Chicago, is sending out samples of its new "Eaco" tape. It is claimed that this tape is composed of one-third pure rubber and has the qualities the trade is looking for.

THE H. C. ROBERTS ELECTRIC SUPPLY COMPANY, Philadelphia, has purchased the fixtures, stock and good will of the Franklin Electrical Supply House of the same city and will fill all unfilled orders previously received by the latter house.

THE UNITED STATES CARBON COMPANY suffered to the extent of $10,000 by fire at its works in Cleveland, Ohio, on the evening of Nov. 19th. The plant was immediately put in order again, and by the time this paper reaches its readers will be working as before.

THE BURT MANUFACTURING COMPANY, Akron, Ohio, has recently received an order for a Cross oil filter from the remote point of Seoul, Corea. The order is from the Seoul Electric Company, the filter being purchased on the recommendation of the chief engineer.

THE SAFETY INSULATED WIRE & CABLE COMPANY of New York City is about to construct a $500,000 manufacturing plant on tide water in the vicinity of Bayonne, N. J. A tract of 15 acres has been secured and it is expected that sufficient buildings will be erected inside of six months to house 400 hands.

MESSRS. GILLESPIE & TARTT, Edwardsville, Ill., have placed on the market "Gillespie's Balance for Incandescent Lamps," the new form consisting of two simple wheels or pulleys around which the lamp cord is run, the upper wheel hanging from the lamp support and the lower one carrying the counterweight.

THE YORKVILLE ELECTRIC CONSTRUCTING COMPANY, New York City, has been formed by Mr. Wm. Jacobs to carry on work in his particular lines of electric bells, electric signs, burglar alarms, gas lighting, telephone work, etc. The headquarters of this company will have facilities for handling the work in these lines.

THE MONTAUK MULTIPHASE CABLE COMPANY, New York City, received most favorable mention in the report of the Committee of Exhibits of the Convention of the National Association of Municipal Electricians recently held in Wilmington, Delaware. The report held that the cable and its appurtenances are a great boon for the protection of life and property.

THE NATIONAL CONDUIT & CABLE COMPANY, New York City, has recently received two large orders for underground cables. One of these covers 150,000 feet of 1,500,000 circular mils lead-covered cable to be used as feeders for the electrical conduit railroad system of the Third Avenue Railroad Company of New York City. The other is a large order from Glasgow, Scotland.

G. E. LINTON & COMPANY, Worcester, Mass., is the name of a new company formed by Mr. G. E. Linton, formerly of the Linton Manufacturing Company, to do a general electrical business. The new company will pay particular attention to the construction of electrical switches and switchboards. Mr. Linton's experience and practical knowledge of this line of work should go far toward assuring the success of the new company.

THE WESTERN ELECTRIC COMPANY is installing three 70-h. p. motors in Schlesinger & Mayer's building, Chicago. These motors are especially designed to drive the pumps for the elevators, and are to work against a constant pressure of water at all speeds. The speed variation, which is from 175 to 350 revolutions per minute, is governed by an automatic controller which cuts in or out various sections of the series field winding.

THE GARTON-DANIELS COMPANY has been incorporated to continue the business of the Garton-Daniels Electric Company, with headquarters at Keokuk, Iowa. It is the intention of the new company to add other specialties to its line of manufact-

ures, announcement of which will be made later. With increased capital and better facilities, the new company will be better equipped than was the old to handle the increasing demand for Garton lightning arresters.

THE AMERICAN DISTRICT STEAM COMPANY has recently occupied newly erected shops in Lockport, N. Y. These shops are 66 x 100 ft. in plan and four stories high, giving room to accommodate the increasing business. The company has recently shipped the material for a complete district steam heating system to the Seattle Heat, Light & Power Company at Seattle, Wash. The system will comprise over a mile of distributing mains ranging in size from 18 in. down

THE SPECIALTY MANUFACTURING COMPANY, Indianapolis, Ind., manufacterer of exhaust, blow and ventilating fans, has removed to new quarters a block from the old location. In the new quarters the company has largely increased facilities and all of the modern factory equipment for turning out a greater product. A large installation of exhaust fans for the Hotel English in Indianapolis was recently completed by this company and is giving satisfactory service.

THE AMERICAN STEEL & WIRE COMPANY, Chicago, reports regarding the partial destruction by fire of its plant at Waukegan, Illinois, Saturday afternoon, November 4th, that arrangements have already been made for the execution of unfilled orders at Waukegan by its other plants, and assures its customers that all orders now placed which have been lodged at Waukegan for shipment, will be taken care of by shipment from other plants with very little, if any, delay.

THE NEW ENGLAND MOTOR COMPANY, Lowell, Mass., is placing on the market a line of iron-clad motors in small sizes ranging from ¼ h. p. to 5 h. p. These machines can be used either completely or semi-enclosed; are fitted with Bayliss reaction-type brush holders and are claimed to be first class in every respect. They are particularly adapted for direct connection to fans, beer pumps, etc., and form a desirable addition to the line of machines already placed upon the market by the same makers.

THE C & C ELECTRIC COMPANY, New York City, reports that it has been recently running behind on deliveries owing to the impossibility of obtaining steel castings, but it is now daily receiving large consignments, which will soon allow it to put on a night force and catch up with orders. The company expects to have ready for the market in a short time the new line of dynamos and motors ranging from two to 40 kw., to be known as the type F. P. The special features of these machines will be announced later.

NO CONSOLIDATION OF THE SPRAGUE AND STANLEY COMPANIES.—At a meeting of the directors of the Sprague Electric Company the consolidation of the company with the Stanley Electric Manufacturing Company of Pittsfield, Mass., was not confirmed, and the companies will be operated independently, although to some extent owned by the same individuals. Mr. Henry Hine will retain his position as General Manager of the Stanley Company. Mr. Allan C. Bakewell was appointed General Manager of the Sprague Company.

THE UNION BOILER TUBE CLEANER COMPANY, Pittsburgh, Pa., has just completed a contract for cleaning two Hazleton, or Porcupine boilers, having over two thousand tubes, each, as is well known, having one closed end. These tubes were badly scaled and the closed end required a special tool of unique design, as well as the use of the company's own design of flexible shaft. This company claims to be the only one on the face of the globe being fully equipped with machinery, tools and expert operators to do this kind of work quickly, effectively and cheaply.

THE PLAYFORD STOKER COMPANY, Cleveland, Ohio, cites a striking example of what can be done toward smoke prevention by the use of proper grates and mechanical stokers in the case of the installation in the Telephone Building in Cleveland. Two boilers with a complete Playford equipment are in use and the most careful observer cannot detect the faintest escape of black smoke from the stack. The combustion of the coal is nearly perfect. This company is also just completing a large installation of forty-five of its stokers for the extensive iron and steel works of the Apollo Iron & Steel Company of Pittsburgh.

MR. P. C. ACKERMAN, who for the last thirteen years has been identified with the American Electrical Works as its representative in New York City, has been appointed general sales agent for the Rhode Island Electrical Works, of Pawtucket, whose officers are Eastwood Eastwood, President; C. G. Wood, Treasurer, and A. F. Montgomery, general manager. The company is now making magnet wires in sizes from No. 14 to No. 40, and Mr. Ackerman is already securing some very nice business. He has opened headquarters at the Havemeyer Building, 26 Cortlandt Street, where he will be glad to receive orders and inquiries and all his old friends.

GEORGE W. LORD, Philadelphia, manufacturing chemist, and proprietor of Lord's boiler compounds, has found it necessary to move into new quarters from the old location which has been occupied so long, twenty-three years, that all possible additions have been made to the building on that site. The new plant is located at 2238 to 2250 N. 9th Street, Philadelphia, where it covers a ground space of 150x175 feet. The building is three stories high, with a base-

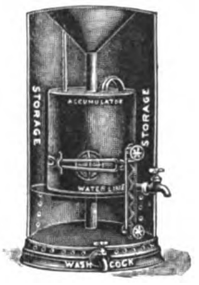
ment, and with foundations and walls sufficiently strong to allow the addition of three more stories in the future. The move was to be made on or about December 1st.

ELMER P. MORRIS gave a dinner at the Bingham House in Philadelphia on the evening of the 14th, in commemoration of the first shipment of material for the new street railway system in Havana, which is being built by the Morris Electric Company of New York. Eighteen gentlemen interested in electrical and transportation enterprises were present. The shipment consisted of 50 carloads, in two trains, of Mason terra cotta conduits from the works of the Potomac Terra Cotta Company, near Washington, which were transported by rail to Philadelphia, and there loaded aboard ship for transportation by water to Havana. The shipment will be followed later by others of trolley poles, tools, machinery, equipment, etc., aggregating in all about 182 carloads. The line will comprise about 27 miles of track.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, Ohio, reports 55 orders for the month of October, the machines ranging in size from the smallest to 300 kw. capacity. A repeat order was received from the Maryland Steel Company of Sparrows Point, Md., this making the fifth order, and being for a 300-kw. generator and several motors. Orders were received from the London, England, "Star" and St. Petersburg, Russia, "Novia Vremia," two of the most important papers of the respective cities, for the Bullock "teaser" equipment for operating newspaper presses. Two 300-kw. alternating-current generators were shipped to the Wilson Aluminum Company of Holcombs Rock, W. Va., to be used in the manufacture of ferro-chrome, an electrical product used in the manufacture of chrome steel.

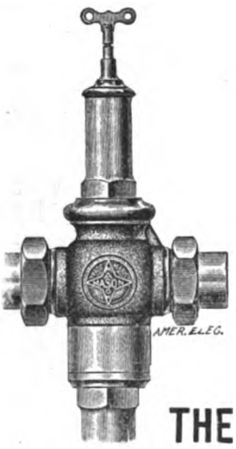


THE HAZARD MANUFACTURING COMPANY has recently extended its works in Wilkesbarre, Pa., previously devoted to the manufacture of steel, iron and galvanized iron rope, to include the manufacture of insulated electrical conductors. The new department is equipped with modern and improved facilities for the production of insulated wires and cables of various types demanded by the market, such as weatherproof, fibre and rubber insulation in standard sizes of wires, and braided, taped or lead-covered cables. The rubber compound is styled by the term "Keystone." The company also makes a "Hazard white core" or "Hazard solid core" insulation. The company also makes bare copper wire, magnet wire, annunciator wire, flexible lamp cords, iron line wire with weather-proof insulation, and galvanized telegraph and telephone wire and galvanized steel wire strand for guy and span wires.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., reports that it has just secured the order for the entire electrical equipment of the Standard Paint Company of Bound Brook, consisting of an American-Ball duplex compound engine and direct-connected generator of 75-kw. capacity, and a full equipment of motors of various sizes for the electrical transmission. Among recent orders for these new duplex compound engines the American Engine Company reports the following: 200 h. p. for Western Electric Company, Chicago; 200 h. p. for Continental Iron Works, Brooklyn; 200 h. p. and 80 h. p., with direct-connected generators, for McCreery & Co., New York; 120 h. p., with direct-connected generator, for Marlin Fire Arms Company, New Haven; two 80 h. p., with direct-connected generators for F. H. Richardson, Newark, and one 80 h. p. for Weston Electrical Instrument Company, Newark.

MR. JAMES G. BIDDLE, Philadelphia, as selling agent for Messrs. Morris E. Leeds & Co., is supplying conductivity testing outfits for the Boston & Montana Consolidated Copper & Silver Mining Company, and also for Professor Robb of Trinity College. These equipments are similar to those which Mr. Biddle has supplied to John A. Roebling's Sons Co., Bridgeport Copper Co., Seymour Mfg. Co., Coe Brass Mfg. Co., Waclark Wire Co., Bridgeport Brass Co., Michigan College of Mines, Guggenheim Smelting Co., Pittsburg Reduction Co., Lake Superior Smelting Co. and Stanley Electric Mfg. Co. It is a matter of vital importance to be able to accurately measure the electrical conductivity of copper wire and rod in small lengths. The same also applies to other metals to a certain extent, especially aluminum, which is now being introduced for transmission purposes. It is believed that the special outfit furnished the Pittsburgh Reduction Co. is the first one that has been used for tests of this character with aluminum.

**NON-TERRITORIAL EXPANSION**



means paying rent for a poor farm. Now is the time to secure a good farm on the line of the Chicago, Milwaukee & St. Paul Railway in Marinette County, Wisconsin, where the crops are of the best, work plenty, fine markets, excellent climate, pure soft water, land sold cheap and on long time. Why rent a farm when you can buy one for less than you pay for rent? Address C. E. Rollins, Land Agent, 161 La Salle St., Chicago, Ill.

# TRANSFORMERS

WE wish to send all users of transformers a copy of our new catalogue. This is just from press, and in it we have described in detail the merits and construction of our Type "K" Transformer.

We would state frankly that this is not a text-book on transformer design and theory, and does not, for example, instruct a station man to replace ten 10-light transformers with one 100 light, nor does it elaborate many other points which are by this time the A, B, C of our alternating current friends.

Our book, however, is a careful presentation of the transformer we build; the text is explicit and fully illustrated. Send for one.

THE PITTSBURG TRANSFORMER CO. PITTSBURG, PA. U.S.A.

# QUEEN ACME PORTABLE TESTING SET.

Circular No. 464—40 pages.

FOR——

Measuring Resistance,
Measuring Insulation,
Checking up Voltmeters,
Measuring E. M. F.,
Battery Resistance,
Murray Loop Test.

Adopted as STANDARD by U. S. and JAPANESE governments.

And also in use in England, Canada, South America, South Africa, Central America, Australia, New Zealand, Russia, Siberia, Etc.

# ..Something New..

**Perfect system for controlling Series Incandescent Lamps.**

**The best Series Governing Device in the world and sold at the lowest price.**

Will control any number of lamps above or below the normal by single lamp steps.

**Standard Boards are built to carry**

From 1 to 70 20-volt Lamps.
From 1 to 56 25-volt Lamps.
From 1 to 47 30-volt Lamps.
From 1 to 28 50-volt Lamps.
When fed from a 1,000-volt primary circuit.

From 1 to 140 20-volt Lamps.
From 1 to 112 25-volt Lamps.
From 1 to 94 30-volt Lamps.
From 1 to 56 50-volt Lamps.
When fed from a 2,000-volt primary circuit.

The device is made to carry almost any desired range of voltage.

*Write for descriptive matter.*

## SHEEHAN & HEWITT,

14 S. WATER ST., NEWBURGH, N. Y.

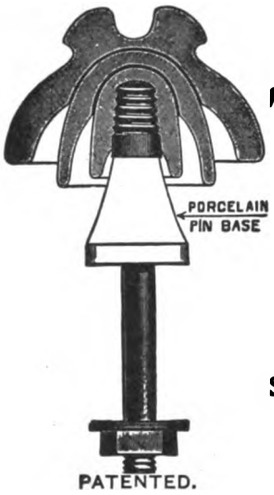
IT doesn't take a hundredth part of a second for a little narrow ribbon of lightning to wipe out several days' profits.

After you have repaired the damage and explained the interrupted service to complaining customers, you have no assurance that it won't happen again, except you equip your lines in a proper manner.

Use at least four Arresters to the mile—keep the discharge out of the Station—that's the vital point.

Get plenty of

# Garton Arresters



they have the smallest air-gap, do not ground your circuits, and are low in price.

Your Supply Dealer handles them, or write us.

# "JAGABI" PORTABLE TESTING SET.

*Comprising*

Quick-acting D'Arsonval Galvanometer, Wheatstone Bridge, Rheostat, Silver Chloride Battery and Keys.

**All mounted in a handsome mahogany case that weighs less than 7 lbs.**

Approved and used by the U. S. Government

**The WILLIAM CRAMP & SONS SHIP AND ENGINE BUILDING CO.,**
OFFICE: BEACH AND BALL STS.

PHILADELPHIA, March 1, 1899.

Mr. JAMES G. BIDDLE, 910 Drexel Bldg., Philadelphia.

*Dear Sir:* I have your favor of Jan. 26th, and in reply to your request concerning the "Jagabi" Portable Testing Set purchased by our Company some time ago, beg to say that it has given us perfect satisfaction in all our work. We have used it considerably on ship-board for insulation tests of the electric light plants after they have been installed and have found it very accurate and a convenient set to handle.

We propose to supply this testing set to the U. S. S. Alabama and the U. S. S. Maine now being built for our Government. This set is more convenient and reliable than any set that we have ever purchased heretofore for use on Government Ships. Yours very truly,

(Signed) CHAS. J. DOUGHERTY, Electrical Dep't.

**Other Specialties:**

Complete Cable Testing Outfits, D'Arsonval Galvanometers, Condensers, Standard Resistance Boxes, Conductivity Bridges, Potentiometers, Laboratory and Station Photometers, Electrodynamometers, Lord Kelvin's Ampere Balances, Weston Volt, Ampere and Watt meters, Bristol Recording Instruments, Silver Chloride Test Batteries, Tachometers, "Iron-Clad" Rheostats, I-T-E Circuit Breakers, Induction Coils and other X-Ray Apparatus.

Send 5c. stamp for

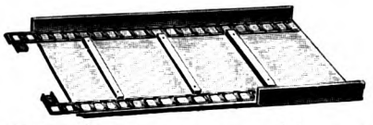
# Why Wait?

Every one of the many thousands of telephone subscribers who have had the service installed at their offices and houses since the introduction of message rates put the service within the reach of all has wondered how he or she had managed to do so long without it.



Why wait longer to wonder later in your turn?

Permanent service at your house or office from $90 a year. All stations have standard equipment; the rate varies only with the use of the service.

NEW YORK TELEPHONE CO.

18 Cortlandt Street. 952 Broadway.
15 Dey Street. 115 West 38th Street.

# AULTMAN

Send us your problems in handling materials, either in bulk or package, and we will submit designs and estimates of machinery to do your work at the lowest possible cost.

## The Adjustable Electrolier

Patented.

For the adjustment of incandescent electric lights to the different heights desired. No unsightly balls or loops of cord, as the extra cord is taken up by the spring balance drum inside the Electrolier.

It is as easily adjusted as your window curtain.
It takes the place of the fuse rosette in common use.

Sample by mail $1.25. Send for descriptive circular and trade discounts.

THE HUNT CABLE RAILWAY.

As seen from the Coal Pocket at the South Brooklyn Power Station of the Brooklyn Heights Railway Co.

# THE HUNT SYSTEM OF COAL HANDLING IN POWER STATIONS

**We build three varieties of Cable Railways:**

**1. Heavy Cable Railway.** The steel cables run constantly, and the cars are attached at will at any point and are drawn around the tracks by the cable until the grip is released

**2. Double Shuttle Cable Railway.** Two cars are used, each running in the opposite direction to the other, passing each other on a switch or on a double track.

**3. Single Shuttle Cable Railway.** One car only is used, which is drawn back and forth by the cable.

Our line is primarily machinery for handling heavy or bulky materials We build Automatic, Cable, and "Industrial" Railways; Hoisting Engines, Steam Shovels, Coal Tubs, Hunt Noiseless Conveyor, Coal Crackers, Coal Chutes, Coal Valves, etc. We make a special Manila rope sold under the trade name of "Stevedore," which we guarantee to be the best rope on the market for hoisting and transmission without any exception whatever.

We have been in this special line of business since 1872 (27 years), and our coal-handling machinery is in use in almost every port of America, and in almost every country in the world. We have ample shops and capital, and manufacture everything we sell, thus we have control over both the quality of material and workmanship that otherwise we could not have. We design and make plans for all classes of wharves, trestels and storage buildings for storing coal and ore, and similar materials.

Write us your requirements. Our catalogues are free to interested parties. Address the works direct.

DESK FAN MOTOR, SIXTEEN INCH.

# FAN MOTORS.

The W. E. Desk and Bracket Fan Motors are made in two sizes, viz.: 12 inch and 16 inch. The 12 inch fans are designed for 110 volts only. The 16 inch fans are designed for 110, 220 and 550 volts. All sizes of Desk and Bracket Fans have three speeds.

The W. E. Standard Ceiling Fan Motor has four blades, and is designed for 110, 220 or 550-volt circuits. It has three speeds; the controlling switch is in the base of the motor. These fans also have chandelier attachments.

SPEED FOUR BLADES 215 R. P. M.
TWO BLADES 235 R. P. M.

The Arctic Ceiling Fans have four blades, and are designed for 110-volt circuits only, but can be run 2 in series on 220 volts, or 5 in series on 550 volts. They are designed with one speed and have no controlling or starting switch in the motor.

SPEED 170 R. P. M.

By using our Special Wall Switch Rheostat the Arctic Fans may be run at three speeds. The Special Wall Switch Rheostat may also be used for any one fan, or series of fans, to control and regulate their speed.

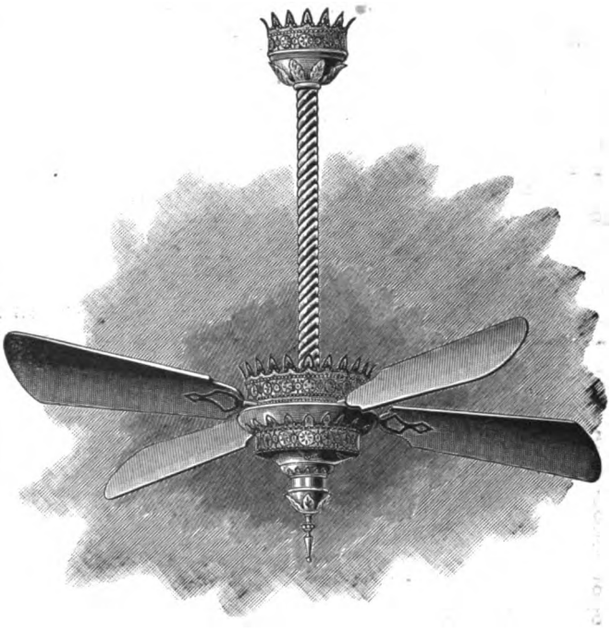
# DIEHL ELECTRIC FANS



FOR ALL CIRCUITS, EXCEPT ALTERNATING.

..SEND FOR CATALOGUE..

Our line of Electric Fans for ALL purposes for the present season is the most complete that we have ever placed on the market, and the high standard of our product has been strictly upheld.

Our Fans are the cheapest because they are absolutely the best made, wear longest, require less outlay for repairs and show a higher efficiency than any other fan. This statement is fully sustained by the past record of our fans. Our place has always been in the lead and we intend to maintain that position.

# Efficiency, Steadiness and Easy Regulation

ARE THE DISTINGUISHING FEATURES OF THE

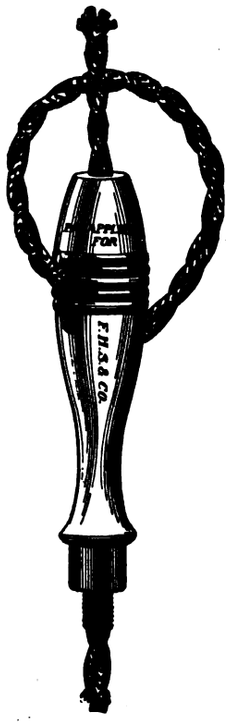
# NEW AMERICAN TURBINE.

The above illustration shows a representative outfit for an installation of a pair of turbines under a high head. By this arrangement are obtained the lowest cost and the greatest strength and rigidity.

Lowest cost, because requiring the smallest dimensions of all its elements, to receive and discharge the required amount of water.

Greatest strength and rigidity, because the quarter turns at the ends brace and support the flume, and the steps in the ends of the quarter turns take up all "end thrust" of the wheel shafts.

Long experience in building turbines enables us to guarantee economy in design and efficiency in results.



**The Greatest Power for a Given Diameter and the Highest Average Efficiency from Whole to Half Water of Any Wheel on the Market. The Most Simple and Durable Construction.**

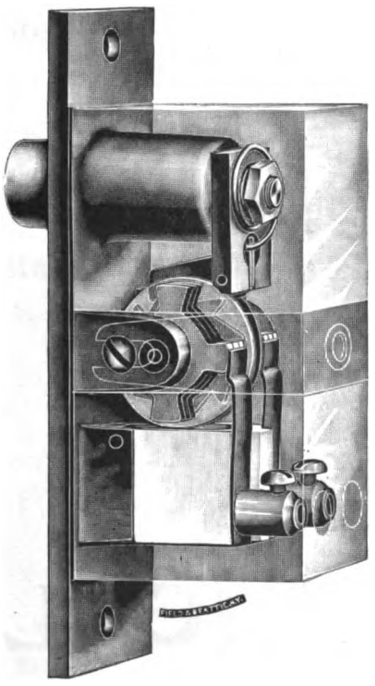
Controlling Rheostat.

**Lundell Fan Motors** are complete and perfect in every detail. Not a single feature of construction has been skimped or neglected. From the smallest screw, to the drop-forged field frames, the workmanship and finish is *perfect*. **The enamel rheostat,** concealed in the base (original with us and diligently imitated by every other maker) is the best device made for this purpose, giving three distinct and widely varying speeds.

This rheostat is far superior to the clumsy affairs generally used. It is mounted on a punched steel base, securing lightness, rigidity and freedom from the breakage incident to porcelain bases.



**The Oil Cups** of the Lundell are the only ones that can be *depended on* to keep the bearings lubricated the entire season without attention. There is no comparison between these cups and cheap grease pots. **Everything considered** the Lundell is the finest and most satisfactory fan motor made, and the most profitable one for Dealers, Contractors and Central Stations to handle. June is the month for business; *will you get your share?* Write for Catalogue 661 if not already supplied.

# VALUABLE IMPROVEMENTS IN HORIZONTAL TURBINE SETTINGS.

**Covered by Letters Patent Nos. 620,964 and 621,141, March 14, 1899.**

These improvements mark the greatest advance of late years in this line of work. Among the numerous advantages gained we mention particularly the following:

**Great Saving in Space Occupied by the Water Wheels, thus Materially Reducing Size and Cost of Power-House, Entire Elimination of Use of Intermediate Racks and Gears for Operating Speed Gates, thus Preventing Lost Motion and Insuring Most Perfect Regulation; Gate Operating Mechanism is all Outside the Flume in Plain Sight of the Operator, and Its Working Part Instead of Grinding in Water as Usual can be Operated in a Bath of Oil.**

The Victor Turbine only is provided with these most valuable improvements. Full particulars on application.

**THE STILWELL-BIERCE & SMITH-VAILE CO., Dayton, Ohio.**

# The Matchless Electric Cigar Lighter

is especially adapted for use in smoking rooms, hotels, cigar stores, marine work, palace cars, apartment houses, office buildings, private residences, **and in fact in all places where cleanliness and freedom from danger from discarded matches is desired.**

The Lighters are made of the finest white china, and are artistically decorated in gold and colors.

The endorsement of the Board of Underwriters and the Fire Department, makes its use doubly advantageous wherever insurance is carried.

It can be used on any voltage current, alternating or direct up to 240 volts, or on battery circuits.

# AT LAST!

The successful single phase motor has finally been produced. We are building for both 60 and 133 cycles.

**MISSOURI-EDISON ELECTRIC COMPANY.**

AMERICAN CENTRAL BUILDING BROADWAY AND LOCUST STREET

ADDRESS ALL COMMUNICATIONS TO THE COMPANY

ST. LOUIS, Oct. 15, 1898.

Wagner Electric Mfg. Co.

E. H. Abadie, Mgr. Sales,

2017 Locust St., City.

Dear Sir:

In reply to your inquiry of even date, we beg to say to you that the single phase A. C. motors, from 1 to 20 H.P., supplied us by your Company, and which have been operated on our lighting circuits for the past 5 to 8 months: have been found eminently satisfactory. Almost without exception our customers are better pleased than with any direct current apparatus heretofore used by them.

As a result of the general satisfaction expressed, together with the manifest advantages to be derived from the use of these motors on our lighting circuits, we shall install during the fiscal year very nearly, if not quite, $25,000. worth of this apparatus, and judge from present indications that about as much more will be demanded by the trade during the ensuing 12 months.

Trusting the above is in full of your inquiry, we are,

Yours very truly;

Missouri-Edison Electric Co.,

S. A. Abadie Secretary.

# WAGNER ELECTRIC MFG. CO.,

## ST. LOUIS, MO., U. S. A.

Digitized by Google

IT IS WELL KNOWN that there are numerous and varied forms of Dry Batteries in the market, but none of them have given entire satisfaction because their powers are quickly exhausted by reason of the **Corrosive Chemicals** employed in their manufacture, and their regenerative forces are very low.

# IN OUR NEW
# Excelsior Galvanic Battery

we place an article before you wherein we have overcome these objectionable short-comings, and is beyond question the long desired article. One trial will convince you of our just claim.

The advantages we claim are:

1—Its absolute cleanliness and strength of cover.
2—Its long duration.
3—High voltage 1.5 to 1.6.
4—It recuperates quickly.
**5—Absence of all acid and other corrosive chemicals.**
6—Long life on open circuit works three years.
7—Keeping its full strength while at rest.
8—Its cheapness.
9—It is absolutely a Dry Battery.

THE

# GENERAL ELECTRIC COMPANY'S Lightning Arresters

are the cheapest form of insurance ever devised.

The General Electric M D Lightning Arresters, embodying the magnetic blow-out principle, are used by all the large companies in the world which make direct current for railway, lighting or power purposes.

The Short Gap Alternating Current Lightning Arresters, for all potentials, made by the General Electric Company, gives ample protection to the circuit, because they are the point of least resistance, though always effective in limiting the generating current.

STEVENS'
# Mechanical Catechism

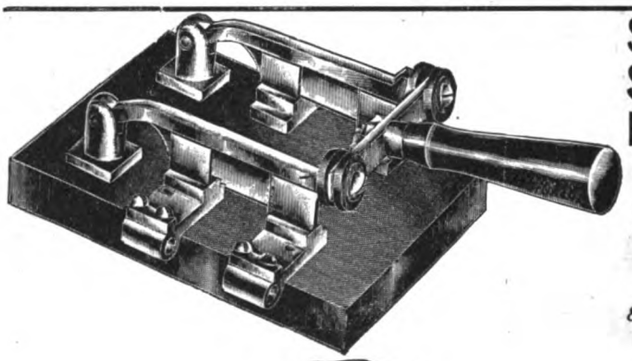
just issued, is a marvel. Like all the reference books published by Laird & Lee, it is crammed full of information, not an inch of space being wasted. All the subjects are treated in the most interesting and thorough manner and in plain, lucid language.

Mechanics and engineers will be delighted with the work. Other books may contain the same information, but Stevens talks the mechanics' language and evidently knows their thoughts, their difficulties and their needs. Intricate problems and purely theoretical questions are entirely omitted.

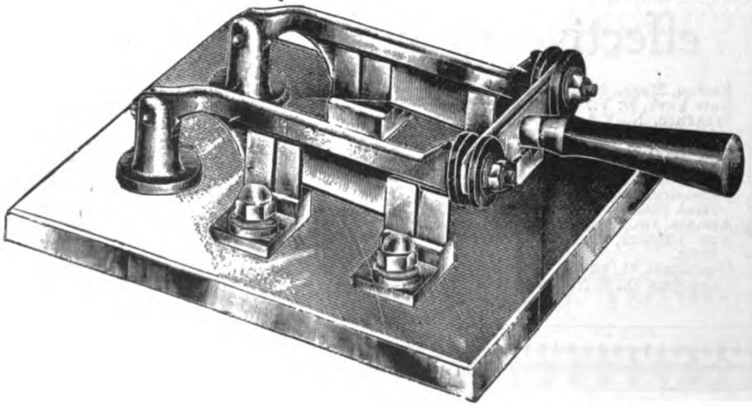
## COMPACT, CONCISE, COMPLETE.

A large part of the subjects are treated in the form of questions and answers, as preparation for Civil Service Examinations.

The Steam Engine is thoroughly explained with all its modern attachments and improvements, Slide Valves, Safety Valves, Injectors, Pumps, Steam Gauges, Lubricators, Eccentrics, Link Motion, Indicator &c. The Traction Engine and Hay Stacker are treated in a special chapter. The Manufacturing of Ice, Refrigeration Machines, Brine and Direct Expansion Systems are treated exhaustively. Also, the Machine Shop, the Electric Plant, House Wiring and Electric Heating. The scientific principle and basis of mechanical work is made clear in every subject, so that the practical hints and directions given are more easily grasped. Calculations of Horse-Power, Pulley-Speed, Lathe-Gearing, Square Root, Leverage, Tensile Strength are made easy, and such puzzling questions as the travel of crosshead and crankpin are solved in a practical, convincing manner. The elements of Algebra are presented in a very happy manner. Useful recipes for emergencies are scattered all through the book.



240 sectional cuts and illustrations. 335 pages. Excellent paper, large clear print. Silk cloth, **$1.00.** Leather, library style, marbled edges, **$1.50.**



**AGENTS!** **The harvest is here.** The fastest selling book of the kind ever published. Now is the time to **make money easily.** Sample copy and terms mailed on receipt of price.

Gentlemen:-

No. 9402.

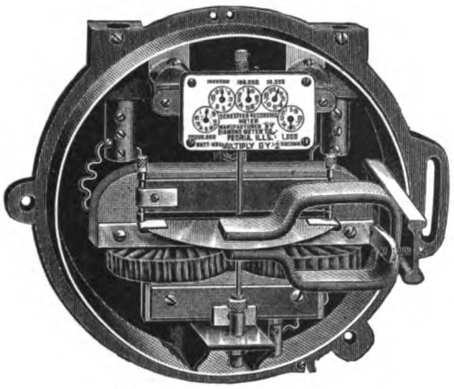
No. 9333.

No. 9364.

No. 9358.

We are now prepared to furnish standard Edison base material in all modifications, including fibre lined key and keyless sockets for 220 volt work and all receptacles and weatherproof sockets which we have been furnishing in the past in T. H. and Westinghouse base. If your system is installed with Edison base material we are confident that this matter will interest you and will be glad on request to mail you our special catalogue devoted to this part of our line.

The sale of supplies manufactured by us is handled entirely through our authorized agents and the larger supply houses.



Every responsible jobber in the United States and Canada is in position to quote upon and ship our goods from stock. If you are unable to obtain our goods promptly from your jobber, kindly write us direct and we will arrange or the proper handling of your orders.

Yours truly,

THE BRYANT ELECTRIC CO.

# NEVER SLIP
# PULLEY COVERING

THE BEST IN THE WORLD

SOLD ON ITS MERITS "NO CURE-NO PAY"

30 DAYS TEST

## With Pulleys Covered with NEVER SLIP PULLEY COVERING

**Nearly double the power can be transmitted than can be with a smooth iron or wood surface. By its use machinery can be run with sagging belts and cool journals without the use of idlers or tighteners—requiring less power and only about half the amount of oil; also increasing the life of both belt and machinery fully one-third.**

**This covering will stand the expansion and contraction of pulley and is not affected by heat, steam, dampness or oil. It is the only liquid covering that has stood the hardest test powerful machinery can give. Always ready for use. Applied with a brush. No expert required. Sold on its merits. "NO CURE, NO PAY." 30 days' test. Each application lasts from four months to two years. Costs 10 cents a square foot.**

### Read What Some of the Users Have to Say of NEVER SLIP PULLEY:

"Your Never Slip Pulley Covering is all and more than you claim for it. We have no more trouble with slipping belts since we began using this 18 months ago. The covering we put on them is still on and as good as ever."
SPRINGFIELD (MO.) LIGHTING CO., H. J. Fox, Supt.

"The Pulley Covering we bought of you six months ago is the best investment we ever made. Your Covering is a success, a saver of fuel and belt leather."
LAPEER (MICH.) ELECTRIC CO.

"We have been using Never Slip Pulley Covering in all our plants for more than two years and find it is all you claim for it and the best covering I have ever had anything to do with."
M. H. PAINE, Master Mechanic,
Heywood Bros. & Wakefield, Chicago.

"Your Never Slip Covering is the best covering we ever used. Our belts are running more satisfactorily than they have for years." GREENSBORO GAS & ELECTRIC LIGHT CO.,
Greensboro, N. C.

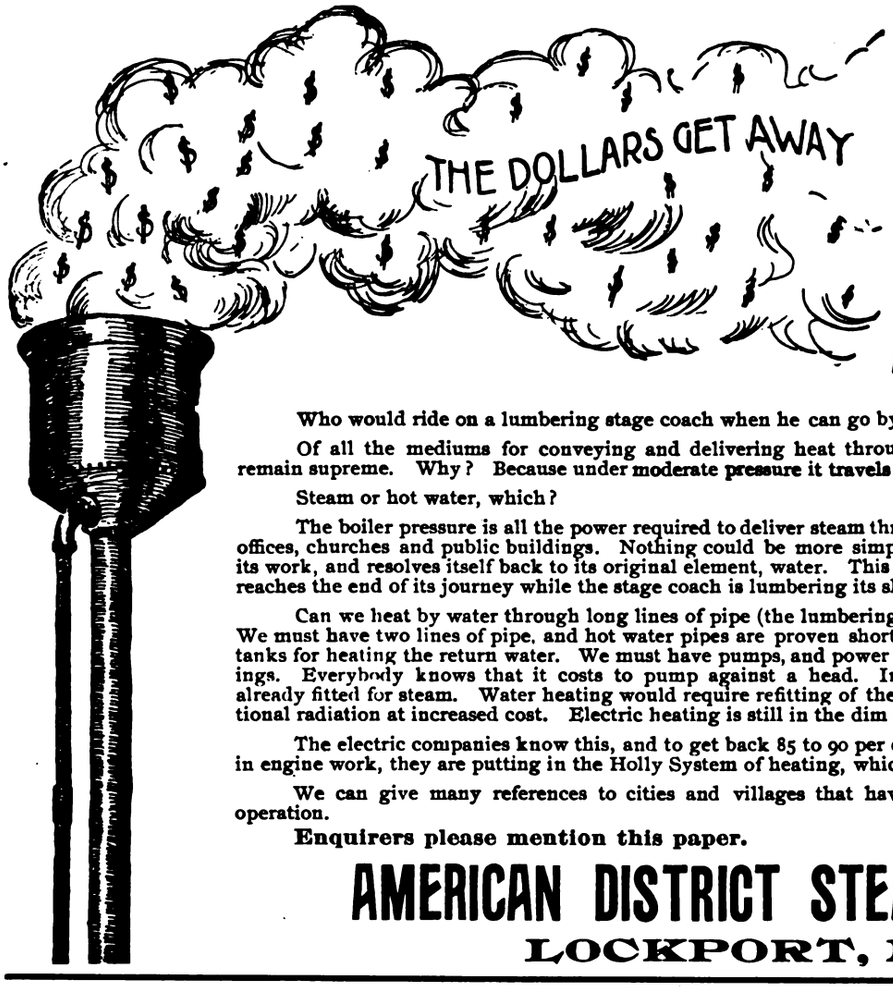
"We have used your Never Slip Pulley Covering on our dynamos and found it to be just as represented. We had great trouble with our belts previous to using this, but after applying this we have no more. Still using the same greasy belts."
ST. LOUIS ELECTRIC LIGHT AND POWER CO.,
Delafield, Mgr.

"Your Never Slip Pulley Covering does the business and is all you claim for it."
COLFAX ELECTRIC CO., Colfax, Wash.

"Your Never Slip Pulley Covering is giving good satisfaction. Send us another gallon at once."
AMERICAN ELECTRIC LIGHT CO., Kansas City, Mo.

"We have given your Never Slip Covering a thorough trial and we find it all that you recommend it to be."
PETALUMA ELECTRIC LIGHT AND POWER CO.,
Petaluma, Cal.

"Your Never Slip Covering is the best we have ever used."
DENISON ELECTRIC LIGHT CO., Denison, Tex.



"Please send us five gallons at once. It is giving good satisfaction."
PENNSYLVANIA MFG. LIGHT AND POWER CO.,
Philadelphia, Pa.

**If you are at all bothered with slipping belts let us send you a trial on our guarantee "NO CURE, NO PAY." Correspondence solicited.**

## A Total Loss.

Who would ride on a lumbering stage coach when he can go by the "Limited?"

Of all the mediums for conveying and delivering heat through long lines of pipe, steam is and must remain supreme. Why? Because under moderate pressure it travels like lightning and gets there.

Steam or hot water, which?

The boiler pressure is all the power required to deliver steam throughout a city to heat its residences, stores, offices, churches and public buildings. Nothing could be more simple. When it reaches its destination it does its work, and resolves itself back to its original element, water. This is the Holly System, "The Limited," which reaches the end of its journey while the stage coach is lumbering its slow and laborious way along.

Can we heat by water through long lines of pipe (the lumbering stage coach)? Yes, but at what expense? We must have two lines of pipe, and hot water pipes are proven short-lived. We must have large and expensive tanks for heating the return water. We must have pumps, and power to force hot water to the tops of high buildings. Everybody knows that it costs to pump against a head. In cities, a large portion of the buildings are already fitted for steam. Water heating would require refitting of these throughout, and 50 per cent. more additional radiation at increased cost. Electric heating is still in the dim future on account of its great expense.

The electric companies know this, and to get back 85 to 90 per cent. of efficiency which they cannot secure in engine work, they are putting in the Holly System of heating, which accomplishes this object.

We can give many references to cities and villages that have this system in practical and successful operation.

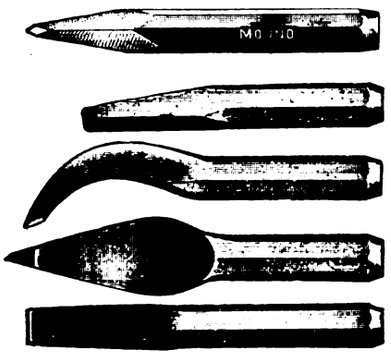
**Enquirers please mention this paper.**

## AMERICAN DISTRICT STEAM COMPANY,
### LOCKPORT, N. Y.

UP TO DATE

# Scraping Tools

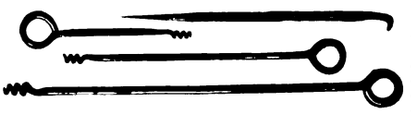
**For Scraping Valves, Journals, Bearings, Etc.**



There are six scrapers, as shown in the cut, in each set. They vary in size from 8 to 14 inches. By improved means they are carefully tempered and nicely polished.

Set of 6 Scraping Tools in Oak Case, $2.25

Acknowledged the best by leading engineers everywhere.



# Cold Chisels

These chisels are made from a high grade crucible steel that costs twice as much as the steel usually found in blacksmith shops, thus insuring good results in forging and tempering. These chisels are made up in sets of 5 tools, a flat chisel, a narrow cape chisel, a bent, grooving chisel for cutting oil ways in engine brasses and bearings, a diamond point and a calking tool, suitable for calking seams and rivets of boilers.

Set of 5 Cold Chisels, . . $1.75

# Packing Tools

EVERY engineer knows the importance and value of good tools around the engine room, and the inconvenience and loss of time and annoyance caused by the lack of them. Not the least in the list of engine room tools is a set of packing tools.

These tools are made from a special tool steel, are warranted not to break or bend in removing packing from stuffing boxes of engines, pumps, etc. Nickle plated finish.

Set of 4 Packing Tools, . . $1.50

" 6 " " . . 2.25

## Automatic Injector....

Is a PERFECT BOILER FEEDER.

GENTLEMEN:—We deem it due to you no less than to the public, that we should make known our appreciation of the National Automatic Injector. Commencing at its price, and ending with its efficiency, it is in our judgment without exception the best injector in the market. We run about 350 horse power boilers day and night, and have used many makes of injectors, and the above is our conviction.

Very truly yours,

# TWO TIMELY BOOKS.

## MECHANICAL MOVEMENTS,

**POWERS, DEVICES, AND APPLIANCES.**

**By GARDNER D. HISCOX, M. E.,** Author of "Gas, Gasoline, and Oil Engines." Large 8vo. Over 400 Pages. 1649 Illustrations, with Descriptive Text. **Price, $3.00.**

A dictionary of Mechanical Movements, Powers, Devices, and Appliances, with 1649 illustrations and explanatory text. This is a new work on illustrated mechanics, mechanical movements, devices, and appliances, covering nearly the whole range of the practical and inventive field, for the use of Mechanics, Inventors, Electricians, Engineers, Draughtsmen, and all others interested in any way in mechanics.

SECTIONS.

SECTION I. MECHANICAL POWERS.—Weights, Revolution of Forces, Pressures, Levers, Pulleys, Tackle, etc.
SECTION II. TRANSMISSION OF POWER.—Ropes, Belts, Friction Gear, Spur, Bevel, and Screw Gear, etc.
SECTION III. MEASUREMENT OF POWER.—Speed, Pressure, Weight, Numbers, Quantities, and Appliances.
SECTION IV. STEAM POWER—BOILERS AND ADJUNCTS.—Engines, Valves and Valve Gear, Parallel Motion Gear, Governors and Engine Devices, Rotary Engines, Oscillating Engines.
SECTION V. STEAM APPLIANCES.—Injectors, Steam Pumps, Condensers, Separators, Traps, and Valves.
SECTION VI. MOTIVE POWER—GAS AND GASOLINE ENGINES.—Valve Gear and Appliances, Connecting Rods and Heads.
SECTION VII. HYDRAULIC POWER AND DEVICES.—Water Wheels, Turbines, Governors, Impact Wheels, Pumps, Rotary Pumps, Siphons, Water Lifts, Ejectors, Water Rams, Meters, Indicators, Pressure Regulators, Valves, Pipe Joints, Filters, etc.
SECTION VIII. AIR POWER APPLIANCES.—Wind Mills, Bellows, Blowers, Air Compressors, Compressed Air Tools, Motors, Air Water Lifts, Blow Pipes, etc.
SECTION IX. ELECTRIC POWER AND CONSTRUCTION.—Generators, Motors, Wiring, Controlling and Measuring, Lighting, Electric Furnaces, Fans, Search Light and Electric Appliances.
SECTION X. NAVIGATION AND ROADS.—Vessels, Sails, Rope Knots, Paddle Wheels, Propellers, Road Scraper and Roller, Vehicles, Motor Carriages, Tricycles, Bicycles, and Motor Adjuncts, etc.
SECTION XI. GEARING.—Racks and Pinions, Spiral, Elliptical, and Worm Gear, Differential and Stop-Motion Gear, Epicyclical and Planetary Trains, "Ferguson's" Paradox, etc.
SECTION XII. MOTION AND DEVICES CONTROLLING MOTION.—Ratchets and Pawls, Cams, Cranks, Intermittent and Stop Motions, Wipers, Volute Cams, Variable Cranks, Universal Shaft Couplings, Gyroscope, etc.
SECTION XIII. HOROLOGICAL.—Clock and Watch Movements and Devices.
SECTION XIV. MINING.—Quarrying, Ventilation, Hoisting, Conveying, Pulverizing, Separating, Roasting, Excavating, and Dredging.
SECTION XV. MILL AND FACTORY APPLIANCES.—Hangers, Shaft Bearings, Ball Bearings, Steps, Couplings, Universal and Flexible Couplings, Clutches, Speed Gears, Shop Tools, Screw Threads, Hoists, Machines, Textile Appliances, etc.
SECTION XVI. CONSTRUCTION AND DEVICES.—Mixing, Testing, Stump and Pile Pulling, Tackle Hooks, Pile Driving, Dumping Cars, Stone Grips, Derricks, Conveyor, Timber Splicing, Roof and Bridge Trusses, Suspension Bridges.
SECTION XVII. DRAUGHTING DEVICES.—Parallel Rules, Curve Delineators, Trammels, Ellipsographs, Pantographs, etc.
SECTION XVIII. MISCELLANEOUS DEVICES.—Animal Power, Sheep Shears, Movements and Devices, Elevators, Cranes, Sewing, Typewriting, and Printing Machines, Railway Devices, Trucks, Brakes, Turntables, Locomotives, Gas, Gas Furnaces, Acetylene Generators, Gasoline Mantle Lamps, Fire Arms, etc.

## LIQUID AIR

**and The Liquefaction of Gases.**

**By Prof. T. O'CONOR SLOANE.**

365 pages. 8vo. Containing many illustrations, with portraits of Faraday, Pictet, Cailletet, Dewar and Tripler. Bound in Buckram.

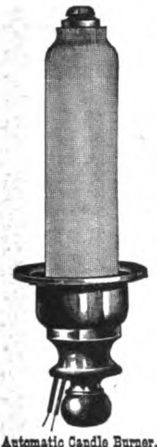
**PRICE, $2.50.**

In offering this book to the public, the publishers feel that, as it is the only work on the subject, they are helping in forwarding the higher scientific education of the people. The world at large is now interested in natural science, and since its earliest developments nothing, with the possible exception of Electricity, has excited such widespread attention as Liquid Air.

This book contains the full theory of the subject. It gives the entire history of the liquefaction of gases, from the earliest times to the present, and also contains a description of all the experiments that have excited the wonder of audiences all over the country. It shows how liquid air, like water, is carried hundreds of miles and is handled in open buckets; also the Formation of frost on bulb—Filtering liquid air—Dewar's bulbs—Liquid air in water—Tin made brittle as glass—India rubber made brittle—Descending cloud of vapor—A tumbler made of frozen whisky—Alcohol icicle—Mercury frozen—Frozen mercury hammer—Liquid air as ammunition—Liquid air as basis of an explosive—Burning electric light carbon in liquid air—Burning steel pen in liquid air—Carbon dioxide solidified—Atmospheric air liquefied—Magnetism of oxygen.

It tells what may be expected from liquid air in the near future. It gives the history and biography of the subject from earliest times.

This is not only a work of scientific interest and authority, but is intended for the general reader, being written in a popular style, and will be easily understood by everyone.



**PRESS NOTICES.**

Prof. T. O'Conor Sloane, the well known writer on physics, has performed the task of bringing together the theory and facts concerning the liquefaction of gases with great ability.—*Scientific American.*

.*. Copies of either book sent postpaid on receipt of price, or special circular sent on request. ☞ Our 96 page catalogue, embracing books on every practical subject sent free to any address on request.

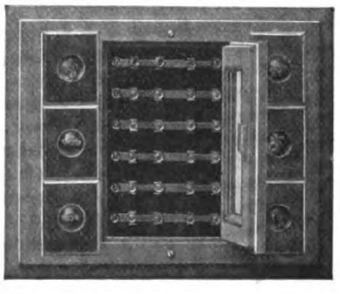
## Our New Type

# JUNCTION BOXES.



## Important Trade Information.

Our New Type Junction are of interest to everyone who has to do with electric lighting, because they excel in being easy to install, and safe and convenient to use.

They are of very substantial construction, and the finish of all parts is the finest that can be made.

Why not get the best when they cost no more than others? A great many people are finding this out, and it will pay you to write us concerning your wants.

# SMALL
# MULTIPOLAR GENERATORS
## FOR DIRECT CONNECTION TO ENGINES.

The type G frame as used for our smaller standard generators has also been adopted for direct connection to engines as shown in the accompanying illustration. The octagonal frame is used and supported from the engine bed by lugs on its side.

The armature is mounted on a shaft, on the end of which is forced a flange coupling, connecting it rigidly to the engine shaft. An out-board bearing, which also supports the rocker arm, is usually supplied by the engine builder.

TYPE "G" D. C. GENERATOR AND ENGINE.

These small direct-connected sets occupy little space and run at so slow a speed that they are practically noiseless, and are being used largely throughout the country for electric lighting on Steamboats, Railroad Trains, and in other placeswhere a small, compact plant is desired.

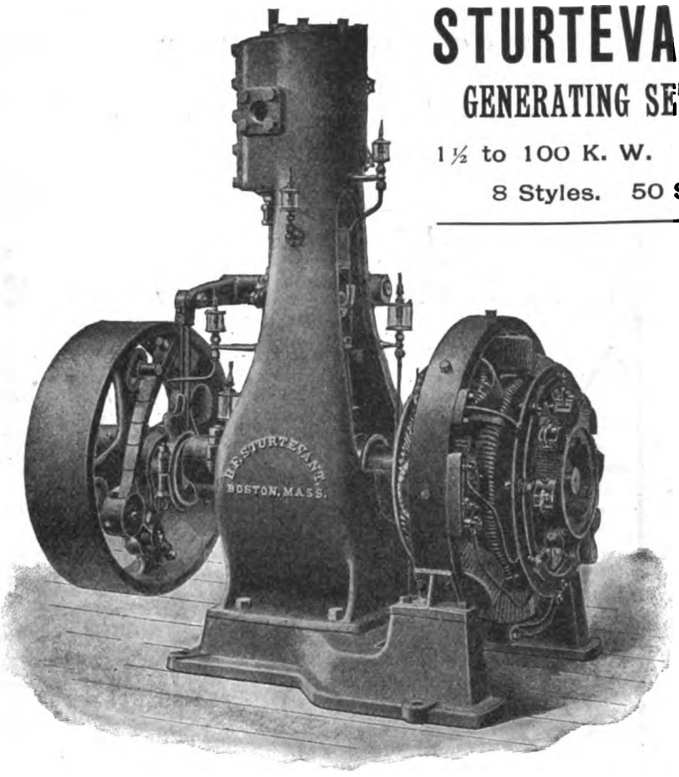
## AMERICAN TELEPHONE PRACTICE

**BY KEMPSTER B. MILLER, M. E.**

**$2.00** ***Is now in press and will be ready for distribution in a short time.*** **$2.00**



This work will form a large octavo volume, and include all of the matter printed during the last two years in the AMERICAN ELECTRICIAN under the same title, revised and brought strictly UP TO DATE, together with a still larger amount of additional matter never before published.

It will cover the PRACTICAL FEATURES OF TELEPHONE WORK, with an attention to detail not found in any other book.

Mr. Miller's experience as telephone expert in the United States Patent Office, and his subsequent experience as chief electrician and superintendent of one of the largest telephone manufacturing companies in this country, has enabled him to write on the subject from its practical as well as its theoretical side.

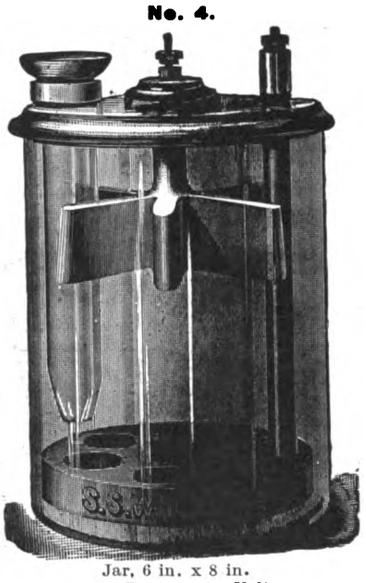
# THE PARTZ ACID GRAVITY BATTERY

FOR ALL OPEN CIRCUIT WORK.

The highest voltage, strongest and longest lasting battery in the world.

AWARDED MEDAL and DIPLOMA AT COLUMBIAN WORLD'S FAIR AFTER COMPETITIVE TESTS.



—: FOR :—

No. 3.

Jar, 6 in. x 8 in.
E. M. F. 1.9 to 2 Volts.
Current on Short Circuit, 1 to 2 Amperes.
**Price $1.50 per cell.**

No. 4.

Jar, 6 in. x 8 in.
E. M. F. 1.9 to 2 Volts.
Current on Short Circuit, 3 to 5 Amperes.
**Price $1.50 per cell.**

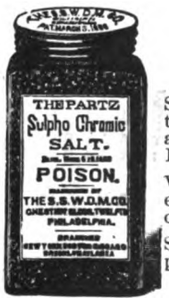
Heavy Electric Bell Work, Annunciators, Open Circuit Electric Signals, Electric Clocks, Watchmen's Clocks, Long Distance and continuously used Telephones, etc.

The attention of Architects, Contractors, Builders, Dealers in Electrical Supplies, Telephone Companies, etc., is called to this Battery.

Send for Catalogue.

Many of the large hotels throughout the country are now replacing unsatisfactory batteries with the Partz Acid Gravity Battery.

# PARTZ SULPHO-CHROMIC SALT



FOR USE IN

PARTZ ACID GRAVITY BATTERIES

AND FOR MAKING

ELECTROPOION FLUID.

*Economy—Safety—Efficiency.*

SULPHO-CHROMIC SALT, when dissolved in water, makes a standard electropoion fluid without the necessity of handling liquid acids, having practically the same amount of stored energy as an equal quantity of fluid made in the ordinary ways, giving with a zinc-carbon element an E. M. F. of 1.9 to 2 volts and an ampere-hour capacity of about the same.

We specially call the attention of battery users to this substance as affording the best, cheapest, and most convenient method of making electropoion fluid for medical batteries, Grenet cells, Bunsen batteries, for lecture tables, experimental work, etc., and motor batteries.

SULPHO-CHROMIC SALT is put up in air-tight jars, with screw-lid, each jar containing two pounds. As the Salt is hygroscopic, it must be guarded against moisture.

**PRICE, PER JAR, 2 LBS., $0.75.**

# Sectional Conductor System

of the

## Safety Third-Rail Electric Company

1. Can be built for the price of a good overhead system.
2. Uses but a single set of third rails.
3. Does away with contact skates.
4. Is able to pick up its switches without the power house current.
5. Storage battery consists of but a few cells, which are continuously charged and require no attention.
6. The car lamps are always lighted, whether the power house current is on or not.

7. The switches open by gravity, rendering the live section in the roadway possible *only under the car.*
8. The switches are absolutely non-arcing.
9. The cars can be operated on a flooded track without danger or inconvenience.
10. The extreme simplicity of the switches makes them absolutely reliable.

You are invited to see all of the above advantages experimentally demonstrated at our offices, and to bring with you the most competent disinterested electrical experts.

Fullest Investigation Solicited.

# Electric Toy-Making.

Very Fully Illustrated $1.00.

**Dynamo Building and Electric-Motor Construction.**

This work treats of the making at home of Electrical Toys, Electrical Apparatus, Motors, Dynamos and Instruments in general, and is designed to bring within the reach of young and old the manufacture of genuine and useful electrical appliances. The work is especially designed for amateurs and young folks.

"This is a work in which the American boy will find explanations of the details of a great number of pieces of electrical apparatus which he may construct with his own hands and for his own amusement and pleasure. The nine chapters of the book treat respectively of batteries, permanent magnets, electro-magnets, electric motors, electric bells, miscellaneous toys, spark and induction coils, and allied subjects, the hand power dynamo, and miscellaneous receipts and formulæ. The chapter on primary batteries will be found especially valuable."—*Electrical World.*

# COCHRANE

# HEATERS

***Converting a waste product into Bank Notes—i. e., U. S. DOLLARS.***

**THE WASTE PRODUCT....Exhaust Steam.**
**THE CONVERTER,.....A Cochrane Heater.**

**THE DOLLARS** *Those you are now paying out for coal that you do not have to burn, those you will have to expend before you can get any more steam—those you are parting with for removing scale, for putting in new tubes, new crown sheets and other repairs.*

And it is all so simple that many pass it by, or else do not believe it. But the savings can be made which we have enumerated above with a **Cochrane Feed-Water Heater and Purifier.**

Because the heaters you are acquainted with won't do it, it does not follow that the "COCHRANES" can't do it.

We would like to show you how they go about it, and then you will agree with us that these very mechanical appliances are based on common-sense principles—that they cannot help giving the results any more than two added to two can avoid becoming four.

All we want is your invitation to submit facts and figures. Catalogue mailed on application.

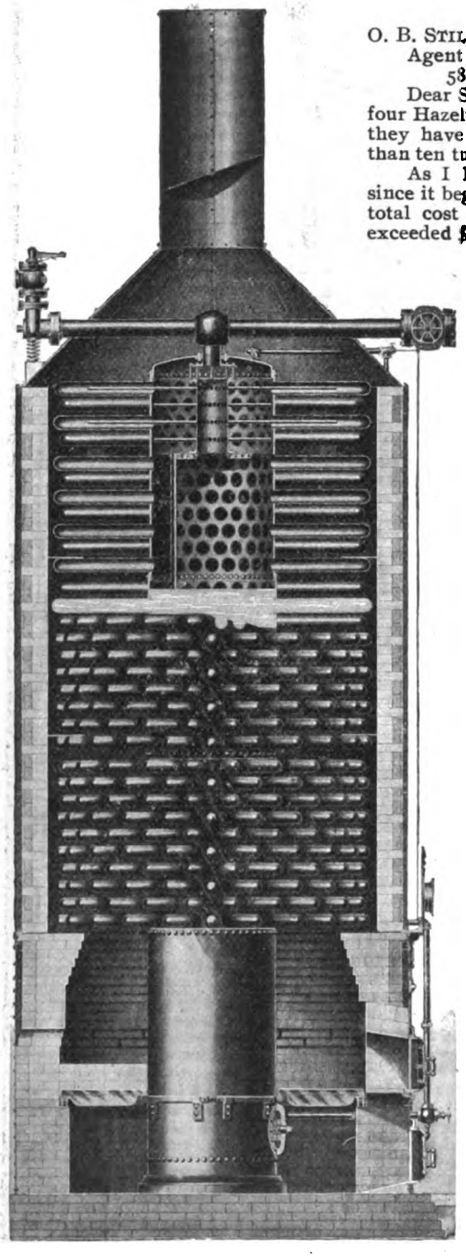
We also manufacture
**The COCHRANE Steam Separators**
for Live and Exhaust Steam Service.

**Harrison Safety Boiler Works,**
**Germantown Junction, PHILADELPHIA, PA.**

Digitized by Google

# THE TRUE COST OF A STEAM BOILER

is its original cost, plus the annual repairs. If these repairs amount to less than half a cent per Horse Power per annum, should you not take this into your calculations in comparing prices of different boilers? Below is the letter of a Boiler Maker who has repaired some of our boilers in Cuba, where the water is very bad. Read what he says and remember it when you wish to add to or improve your steam plant.



CIENFUEGOS, CUBA, April 26, 1897.

O. B. STILLMAN, Esq.,
Agent HAZELTON BOILER CO.,
58 William St., N. Y.

Dear Sir:—This is to certify that seven years ago I erected four Hazelton Boilers of 300 H. P. each on Central Soledad, and they have worked up to date without any repairs, not more than ten tubes being replaced.

As I have done all the repairs to Boilers on this Estate since it began, I can speak with certainty when I say that the total cost of repairs on these 1,200 H. P. of boilers has not exceeded $25.00 in seven years.

Very truly yours, DANIEL McCARTEN.

# The ONLY Governor that will Successfully Govern any Type of Engine.

Built with automatic safety stop, speed adjuster and valve lever and fitted with special chambers to suit any style of Gas Engine or motor of the Throttling Type.

By means of the multiple valve movement with which this Governor is provided, very close and accurate results are obtained so that for a given radial movement of the Governor balls, the lift of the valve may be made greater or less without changing the radial position of the balls or effecting the speed of the engine. The excellent design of this Governor makes it an ornament to any engine on which it is placed.

The Monarch Governor.

## THE MONARCH GOVERNOR

is patented in the United States and Canada and all of the principal countries of the world. Bids for the manufacture of the Governor or sale of patents are still open in the following countries: Great Britain, Germany, France, Hungary, Austria and Belgum.

**THE MONARCH GOVERNOR & MACHINE CO., Incorporated, INDIANAPOLIS, Indiana, U. S. A.**

# Murphy Automatic Smokeless Furnace

## THE ONLY FULLY AUTOMATIC FURNACE

## SUPERIOR RESULTS ON ALL POINTS

1st. "THE MURPHY" is the most completely smokeless furnace made, whether the coal used be of the bituminous, semi-bituminous, or mixed class.

2nd. It is more economical in both fuel and labor than any other in use.

3rd. It will give the largest maximum capacity per square foot of grate surface under like conditions of fuel and draft.

4th. It is more durable, when intelligently used, than any other, whether hand fired or mechanical.

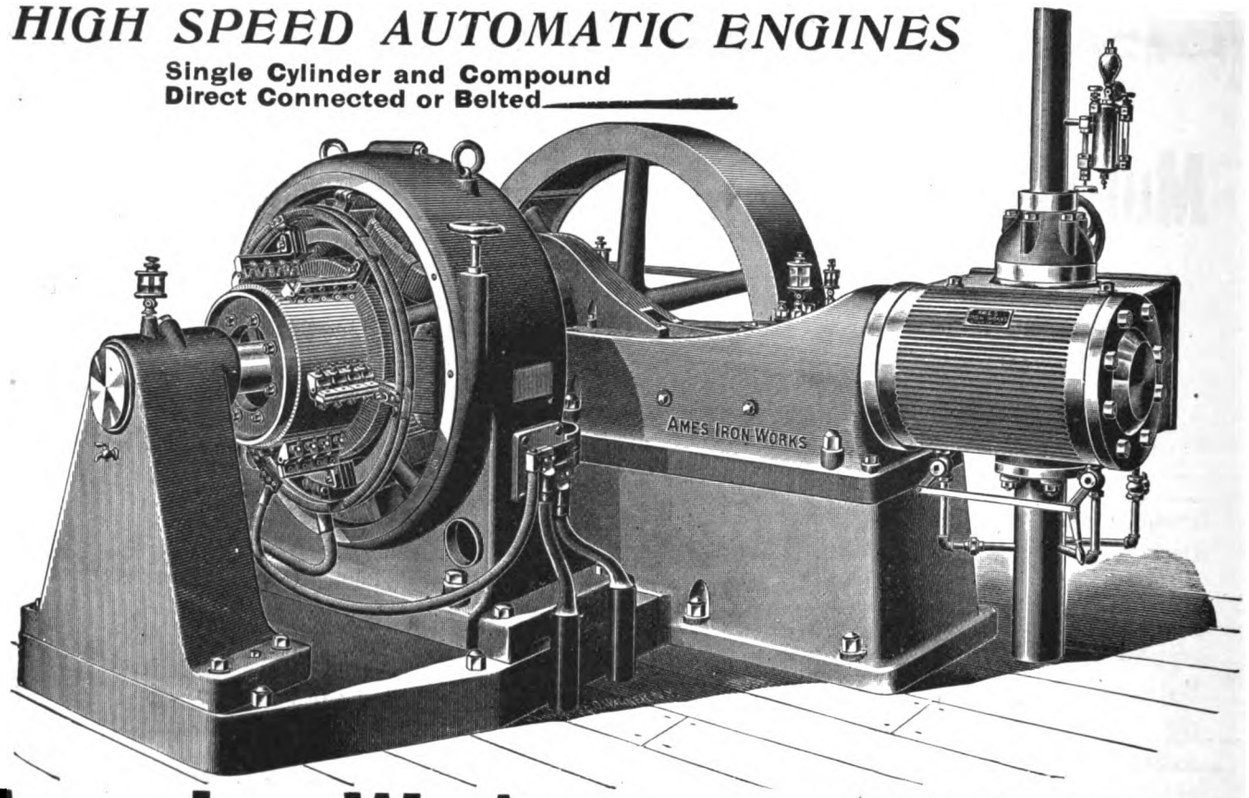
5th. It will utilize to better advantage any cheap grade of soft coal, such as slack, screenings, or a mixture of hard and soft coal screenings.

6th. Steam can be raised more readily to any given pressure and can be maintained more regular under varying conditions of duty or load than with any other.

7th. Coal and ash handling machinery—either or both—can be more advantageously applied to it than to any other, and it is more efficient and satisfactory in general service under the usual normal conditions of regular work in steam power plants.

We desire to call special attention to the fact that "THE MURPHY" is the ONLY "STOKER" that is SELF-CLEANING, and the only furnace that deposits the ash and CLINKER AUTOMATICALLY INTO the ASH-PIT, and the only one that breaks up the clinker in a condition to be handled by a conveyer, and can, therefore, be operated in connection with either or both coal and ash conveyors with less labor than any other. It is also the only furnace in which 25 pounds and upwards to 40 or 50 pounds of bituminous coal can be burned per hour per square foot of grate WITHOUT SMOKE.

*BRANCH OFFICES:*
*Chicago, Ill., Bedford Building.*
*Cincinnati, O., Neave Bldg.*
*Pittsburg, Pa., Lewis Block.*



*MURPHY IRON WORKS*
*DETROIT, MICH.*

P. S.—We wish to call the attention of those who are using our older forms of construction to the fact of recent improvements, which can be applied to all our furnaces, making the furnace more completely self-cleaning and more durable and satisfactory than ever.

THE

# GENERAL ELECTRIC COMPANY'S

# Type H Transformers

give maximum life, minimum repairs and minimum burn-outs. They embody the experience of twelve years in transformer building and are warranted to give the best general results, without the sacrifice either of current economy or of the useful life of the apparatus.

Type H Transformers were the first transformers in which oil was used as the most effective method of insulation and cooling, and they still give the lowest temperatures for any given output. Specially prepared oil is furnished free by the General Electric Company for these tranformers in order that the best results may be secured. No durable transformer can have a rise in temperature due to resistance exceeding 50° C.

Estimates made on new transformer systems, with a saving on installation of from 10 per cent. to 30 per cent.

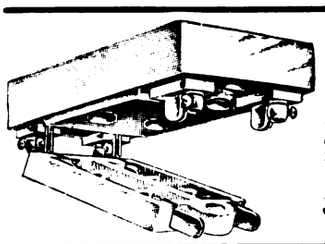
*A Word to the Wise.*



Does your gasoline cost you $2.00 a month?

Half the Gasoline Saved
Means something, don't it?

A No. 1 or Special Fire Pot
Will save half the gasoline and half the time.

Clayton & Lambert Mfg. Co.,
Special Fire Pot, $4.50 net. Catalog Free. DETROIT, MICH.

IN WRITING TO ADVERTISERS PLEASE MENTION THE AMERICAN ELECTRICIAN.

THE FAGAN
Cut-out and Switch.

Placed on ceiling—opens and shuts with cord. For controlling either incandescent or arc lamps. Obviates running wires down walls.

MANUFACTURED BY
J. C. FAGAN, Watertown, N. Y.
For sale by all Supply Dealers.

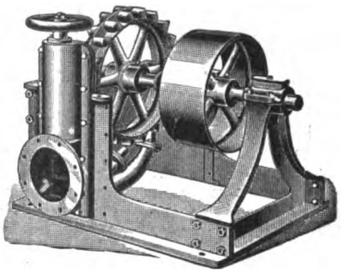
# WATER WHEELS

ADAPTED TO ALL HEADS FROM

**3 Feet to 2000 Feet.**



ESPECIALLY ADAPTED TO ALL KINDS OF

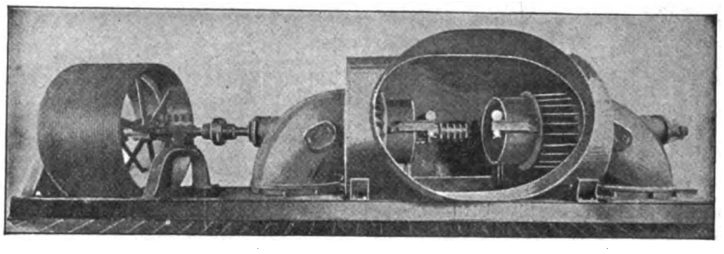
**ELECTRIC POWER and LIGHTING PLANTS**

Recent tests at Holyoke enable us to guarantee:

*The largest power ever obtained from a Turbine of the same diameter*
*The highest speed ever obtained from a Water Wheel of the same power*
*The highest mean efficiency ever obtained when running at half to full gate.* We guarantee also: *A runner of the greatest possible strength. A gate unequaled in quickness and ease of opening and closing.*

Our experience of **36 Years** building Water Wheels enables us to suit every requirement of water power plants. Complete satisfaction is guaranteed. Send for pamphlet, and state your **head** and full particulars.

**AUTOMATIC STEAM ENGINES** With Suitable BOILERS



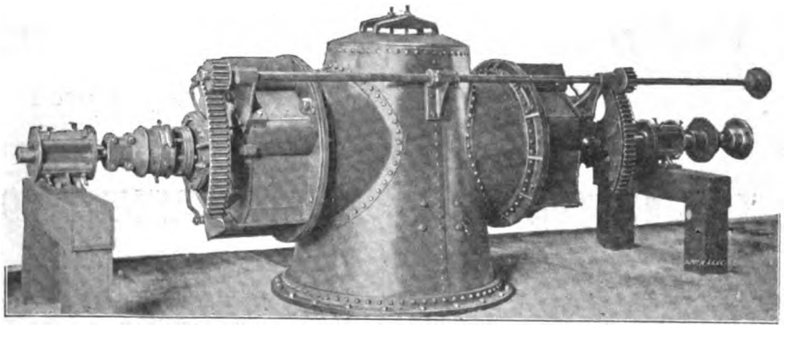
Built in latest style, of latest design, and **highest excellence.** Sizes from 3 horse power upwards. Send for Engine Pamphlet D.

**JAMES LEFFEL & CO.**

SPRINGFIELD, OHIO, U. S. A.

# McCORMICK TURBINES.

**Estimates furnished for Complete Power Plants, and results guaranteed. State your requirements and send for Catalogue. . . . . .**



Represents a pair of 51-inch McCormick Turbines, 1800 H.P., with 10-foot diameter rope sheave, carrying 27 ropes 1¼ inch diameter, driving 750-K.W. generator in No. 2 station of the Sacramento Electric, Gas & Railway Co., Folsom, Cal. This company are using in their No. 1 station four pairs of 30-inch turbines of same make, developing 5000 H.P., which are direct-connected to four generators, transmitting power 23 miles to Sacramento.

HUNT STEAM HOISTING ENGINE
WITH COUNTERWEIGHT

HUNT ELECTRIC HOISTING ENGINE.

## HUNT HOISTING ENGINES

In connection with our coal handling machinery we make special heavy duty hoisting engines adapted to rough, hard, continuous work. The steam engine shown has our spiral drum counterweight attachment to balance the weight of the steam shovel. This greatly increases the capacity of the engine, as it has to hoist coal only and not both coal and the shovel. All working parts are extraordinarily heavy and the wearing surfaces large. To prevent danger from frost all steam passages are arranged to drain condensation away automatically.

ELECTRIC HOISTING ENGINES, built for heavy and continuous work, from 5 to 150 horse-power, and having drums, clutches, brakes and other parts corresponding to those usually used with steam hoisting engines.

Our line is primarily MACHINERY for HANDLING things heavy and bulky. COAL HANDLING MACHINERY, "INDUSTRIAL RAILWAYS," "CONVEYORS," besides our "STEVEDORE" transmission and hoisting ROPE.

Write us your requirements. Our line is a large one and we are always glad to send catalogues and information if we know what is required. Please address the works direct.

Digitized by Google

**The Resistance Wire** in our constant potential Arc Lamps is mounted absolutely fireproof. The separate turns of the wire are laid in the grooves on the surface of a large porcelain cylinder, so that **they cannot sag** and short-circuit on one another.

The wire is **not coiled** in a small spiral, and therefore is mechanically more sound than wire so wound. The adjustment is made by moving a band up or down, and **is the work of but a moment.** The resistance is not placed inaccessibly at the top of the lamp but is placed so that **it becomes accessible by merely lowering the outer globe.** All other points of the lamp are designed with equal care.

# "MIDGET"

# Enclosed Arc Lamp

...FOR...

## CONSTANT CURRENT CIRCUITS.

**For** Street Lighting and Commercial Lighting

Is more economical in operation than any other constant current enclosed arc lamp on the market.

Will burn 125 to 150 hours with one 12 x ½ inch solid carbon.

Has been successfully used all over the country for more than two years by electric light stations and large corporations.

Burns on circuits of from 5 to 7 amperes without any change in adjustment. All other makes of constant current lamps require readjusting.

At 5 amperes equal to 1200 C.P. open arc lamp.

At 6.8 amperes equal to 2000 C.P. open arc lamp.

Gives steady white light, with no noise, flashing or dropping of sparks.

Where desired, we furnish a positive cut-out of compact and improved design.

For indoor service the single globe lamp can be furnished. For street service a metal reflector can be furnished in addition to the double globe.

**Full particulars, Circulars and Prices, furnished on application.**

# FRINK'S PATENT SPECIAL WINDOW REFLECTOR.

Patented April 20, 1897.
No. 581,093.

## FORTY YEARS OF LIGHT.

NINETY-NINE per cent. of store windows are imperfectly lighted, and especially so where electric lamps are used. Most of the lamps are scattered on the bottom and at the sides of the windows, where they can be seen by lookers in, and where they attract more attention to *themselves* than to the goods they are imperfectly lighting. The *ideal* window light should light the *goods* and not be seen while doing so.

**FRINK'S SPECIAL PATENT WINDOW REFLECTOR** for Electric Light, lined with Silver-Plated Corrugated Glass, is placed in top of the window near the front glass, reflecting the light inward and downward. This makes a very desirable window reflector, as the reflectors are put out of the way and concealed from view, at the same time concealing the direct light from the eyes of the observer, and giving a strong, even light down where wanted, thus doing away with the annoyance of a dazzling light in the eyes. We strongly recommend this style of reflector as the very best store window light in existence, and it has been adopted by leading stores in the principal cities in the U. S. It is used also largely for lighting Art Galleries, Pictures, Stock Exchange Boards, Border Lights, Telephone Switchboards, etc.

**We will consider it a favor if contractors and supply houses will send us the names of parties using or about to use an imitation of this reflector and by whom installed.**

To get results, Reflectors should be used entire width of window, with lamps 9 or 12 inches apart, as desired.

THE FIRST PRIZE AT THE FIRST GREAT AMERICAN EXPOSITION. THE FIRST PRIZE AT THE LAST GREAT WORLD'S FAIR.

Descriptive Circulars and Prices on Application.

# 50 Volts vs. 100 Volts.

Low volt lamps of the same manufacture have always been known to be superior to high volt lamps. Prominent makers guarantee 13 per cent. better results from low volt than from 100-125 volts. The reason is that the former are "treated" lamps or "flashed" at a higher temperature and have a greater percentage of denser, pure deposited carbon.

**Bryan-Marsh New Double Filament Lamps** have two 50 volt filaments in series. In consequence, under specification, their guarantees of candle area are higher than any competitor, and owing to their durability, 31 watt lamps can often be used where 35 watts were formerly used.

# HERE IS A PICTURE OF A TRANSFORMER.

It is similar in principle and appearance to all other transformers. It has a primary, a secondary, and an iron core just like all the rest.

Why is this transformer better than any other?

Here are two reasons:

It is insulated highly.

Its iron core is of the best grade for the purpose, and there's a difference in irons.

Good iron requires little magnetizing current and stays cool.

Good iron costs money. The demand for it is great; it is hard to get.

Good iron is used in Royal Transformers. They don't ***look*** any better for it, but they are not sold on looks.

Good insulation also, like good iron, does not show on the surface, but in the performance.

You can't determine the relative merit of Royal Transformers by looks, catalogues, or advertisements. What then? By a sample order.

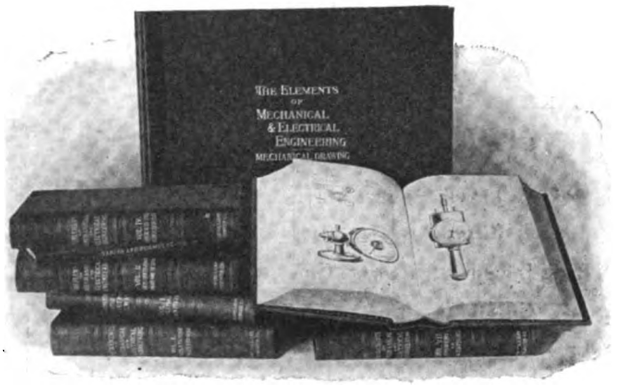
# OUR STUDENTS SUCCEED



## Our Success has resulted from the Success of our Students.

In 1891, our manager, Mr. T. J. Foster, originated a system of instruction which offered its students a certain means of advancement. If the instruction had failed to advance men in their positions and increase their salaries, these wonderful Schools would not exist; but **results**, quick and sure, have developed them in nine years from an experimental undertaking to the largest and most popular educational institution in the world.

## Nine Electrical Courses.

**Electrical Engineering, Electrical, Electric Power and Lighting, Electric Lighting, Electric Railways, Telephony, Telegraphy, Electric Mining, Wiring and Bell Work.** Electrical Instruction in charge of Prof. R. B. WILLIAMSON, formerly Professor of Electricity in Lehigh University.
**112,000 STUDENTS AND GRADUATES. September, 1899. Capital, $1,500,000. $12 to $70, in Small Monthly Installments, pays for a**

## Salary-Raising Education.

**DUPLICATE SETS OF INSTRUCTION PAPERS, BOUND IN HALF LEATHER.**

In addition to the regular Instruction Papers—sent to the student as fast as he requires them—the price of each Course includes a complete duplicate set of the Instruction and Question Papers and Drawing Plates, finely printed and illustrated, bound in half leather. These are delivered to students as soon as they enroll on the cash plan, or as soon as the second installment payment is made. They are far superior to any ordinary books published, as they commence at the fundamental processes, fully and clearly explain every important principle, and qualify the student for work of the most difficult character. The Electrical Engineering Course includes the best treatise in print on the Theory and Design of Alternating-Current Apparatus. Our students say: "The Bound Volumes are alone WORTH THE PRICE OF THE COURSE."

**RAISED $70.00 A MONTH.**
When I enrolled in the Electrical Engineering Course, I was working as second engineer for The Orville Light, Heat & Power Co. Now I am General Manager and Treasurer for the same Company, increasing my salary $70.00 per month, for which I credit The Schools. I take pleasure in recommending The International Correspondence Schools to all those who are anxious to better their condition.—C. V. GILBERT, Orville, Ohio.

**ENDORSED BY PROMINENT ENGINEER.**
My advice to any person who can spare a little time each day for study is to enroll in the Schools. I can honestly recommend the system of instruction, as I have been very much benefited by it, and others whom I have helped to enroll have also derived great benefit. I am now Electrical Engineer for the S. D. Warren & Co. Paper Mills, the largest paper mills in this country.—WM. B. BRAGDON, Westbrook, Me.

**GENERAL FOREMAN BENEFITED.**
When I enrolled in the Mechanical Drawing Course, I had no knowledge whatever of the subject. Now I feel qualified to handle any line of drafting in my business. I afterwards enrolled in the Complete Mechanical Course. My studies have been of great benefit to me in my position as General Foreman of the Car Department of the Lake Shore & Michigan Southern Railway.—R. W. BURNETT, Englewood, Ill.

**A MASTER MECHANIC'S OPINION.**
I have just completed the Locomotive Engineering Course, and have enrolled in the Electrical Engineering Course. I have found the method of instruction very systematic and complete. The Instruction Papers treat the various subjects in a very exhaustive manner. I have been greatly benefited since I became a student and now have a responsible position as Master Mechanic of the Central Railroad Co. of New Jersey.—J. S. CHAMBERS, Elizabethport, N. J.

**SUBSTANTIAL INCREASE IN SALARY.**
I can recommend The International Correspondence Schools with pleasure. I enrolled in the Electric Power and Lighting Course, November 30th, 1897, and through the commendation of The Schools I secured a position as Electrical Engineer for the Blakely Light Plant, Peckville, Pa., at a substantial increase in salary.—EDGAR M. BARNES, Peckville, Pa.

**BECOMES ELECTRICAL SUPERINTENDENT.**
It gives me great pleasure to speak of the merits of The International Correspondence Schools. My Course in Electric Power and Lighting has benefited me in several ways. When I enrolled I was working as a stationary engineer. The education I received was so thorough and practical that it fitted me for the position, which I obtained through the help of the Schools, as Superintendent of The Lansdale Electric Light Works. —JAMES M. FINE, Lansdale, Pa.

# Electric Toy-Making. Very Fully Illustrated $1.00.

**Dynamo Building and Electric-Motor Construction.**

This work treats of the making at home of Electrical Toys, Electrical Apparatus, Motors, Dynamos and instruments in general, and is designed to bring within the reach of young and old the manufacture of genuine and useful electrical appliances. The work is especially designed for amateurs and young folks.

"This is a work in which the American boy will find explanations of the details of a great number of pieces of electrical apparatus which he may construct with his own hands and for his own amusement and pleasure. The nine chapters of the book treat respectively of batteries, permanent magnets, electro-magnets, electric motors, electric bells, miscellaneous toys, spark and induction coils, and allied subjects, the hand power dynamo, and miscellaneous receipts and formulæ. The chapter on primary batteries will be found especially valuable."—*Electrical World.*

# HART H. & H. PUSH SWITCH

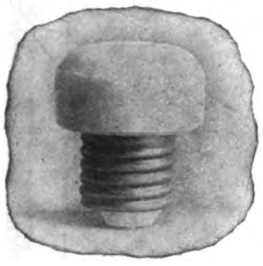
Patented Nov. 30, 1897; May 17, 1898.

## WITHOUT A RIVAL

**It is easy to push. It is always in order.**
**A favorite wherever known.**

WHERE an easy-working, reliable and up-to-date appearing switch is desired, the HART H. & H. Push Switch will be found to comply fully with all requirements. A child can push the buttons without strain or injury to the fingers. Design, workmanship and material are first class in every respect. The switch is highly commended by all prominent electrical engineers. Made in the following styles :

No. 701. Single Pole. No. 703. Three-way.
No. 702. Double Pole. No. 704. Four-way.



Also in gangs of any desired number.
Stock finishes are nickel, polished bronze and brass.
Special finishes to match hardware, are furnished to order.
Stock sizes in gang plates for from two to six switches.

**SOLD AND CARRIED IN STOCK BY ELECTRICAL SUPPLY DEALERS EVERYWHERE**

Specify "Hart H. & H." Push Switch when next ordering and you will be well pleased with results.

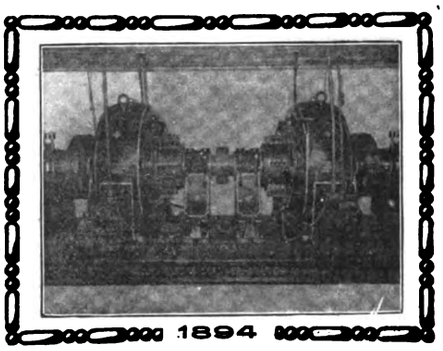
# WE DESIGN AND BUILD
# COMPLETE ELECTRIC POWER PROPERTIES.

## OUR RECORD.



The plants of the following companies were built from the designs of the president of this company, while acting in the capacity of consulting engineer :

1893

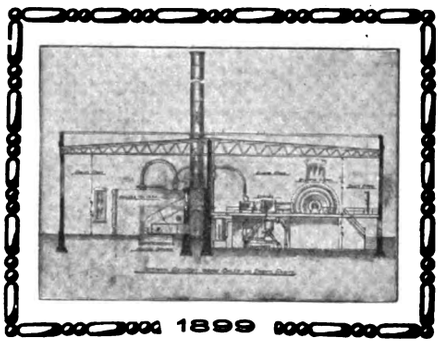
COLUMBIAN INTRAMURAL RAILWAY
at the World's Fair.
The **FIRST** successful elevated electric road in the United States.

1895

CHICAGO BOARD OF TRADE.
The **FIRST** isolated plant to successfully operate arc lights, incandescent lamps, motors and electric elevators, off one set of mains, by means of a storage battery.

1894

ENGLEWOOD & CHICAGO ELECTRIC RAILWAY.
The **FIRST** successful storage battery road in the United States.



THIS COMPANY DESIGNED AND BUILT

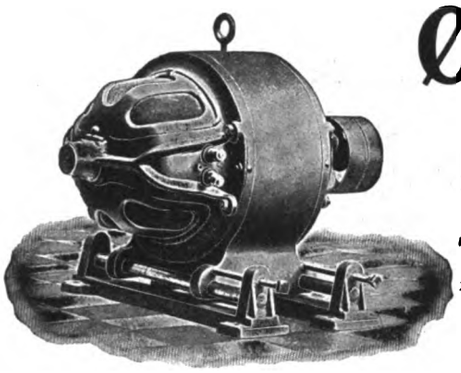
1898

The power station of
THE IMPERIAL ELECTRIC LIGHT, HEAT & POWER CO.,
OF ST. LOUIS.
The **FIRST** direct current central station in the United States to successfully operate incandescent lamps, arc lamps and 250 and 500-volt motors, off one set of mains.

1898

The complete light, heat and power plant of the
CHICAGO GREAT-WESTERN RAILWAY,
AT OELWEIN, IA.
The **FIRST** plant to utilize magnetic clutches for connecting shafting.

1899



The entire equipment, excepting track of the
CHICAGO & MILWAUKEE ELECTRIC RAILWAY.
The **FIRST** long distance electric railway operated from a central steam station using three-phase transmission, rotary converters, sub stations and battery auxiliaries.

**In each of the plants built by this company a stipulated economy was guaranteed under a bonus and forfeiture contract**
**This company is prepared to submit propositions on complete electric plants for any purpose, under reliable guarantees, after learning particulars.**

NEW CATECHISM OF ELECTRICITY. A PRACTICAL TREATISE PRICE, $2.00.

# For Engineers AND Dynamo Tenders

**Catalogue sent upon request.**

Engineers desiring a practical book on everyday electrical practice will find that this book fills all requirements, as it treats fully upon Dynamos, Motors, Wiring, Electric Lighting, Bell-fitting, Electric Batteries, Telephones, Electric Elevators, Pumps and Railways. It is also in itself a dictionary of Electrical Words and Terms. The volume is bound in handy pocket-book form, red leather, gilt edges and gold titles. It has 550 pages of up-to-date information and is fully illustrated with 300 cuts.

This work will be sent postpaid upon receipt of $2 00, to any address in any part of the world. To the patrons of the AMERICAN ELECTRICIAN it will be supplied, if desired, on easy terms of payment, *i, e.*, $1.00 with order, and $1.00 in 30 days. Send remittance by Post-Office or Express Money Order. Book will be sent on first payment.

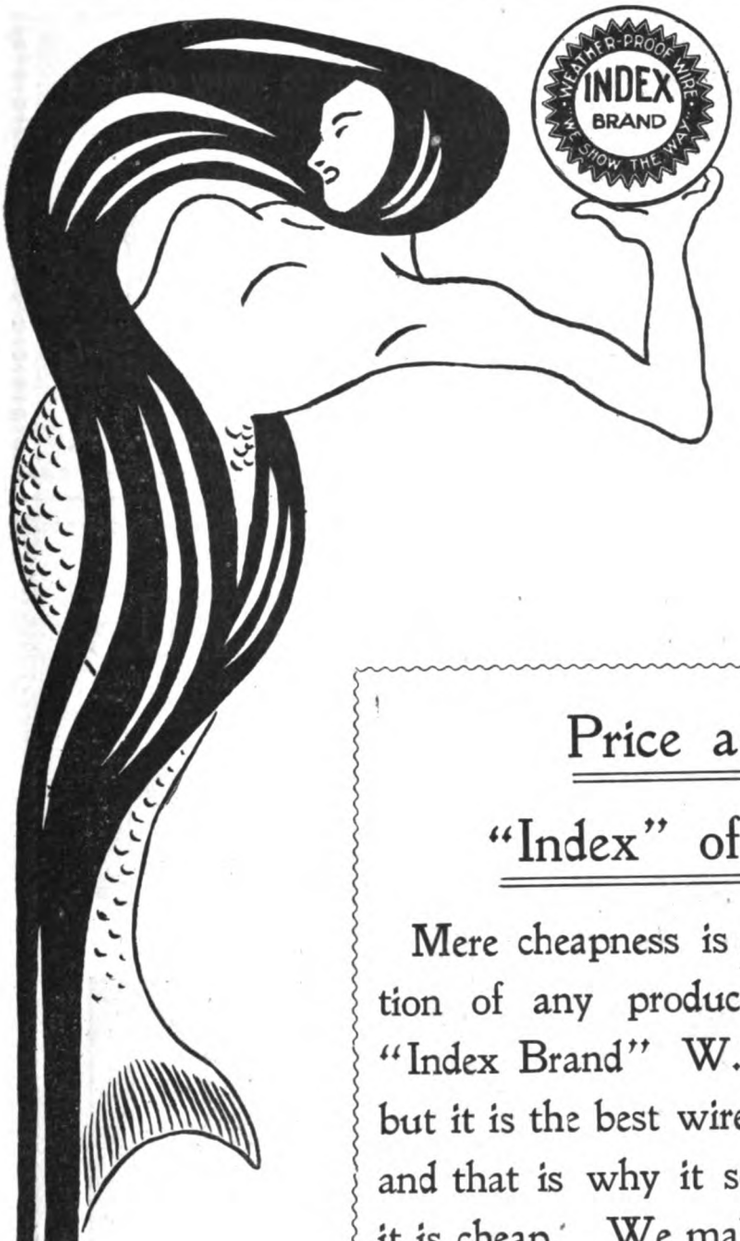
CLING-SURFACE MFG. CO.,
BUFFALO, N. Y. BOSTON, MASS., Aug. 1, 1899

GENTLEMEN.—Having tried Cling-Surface on my 12" dynamo belt (16 feet between centres), I have been able to carry full load with 22" sag on belt with no perceptible slip. It surpasses my expectations and I can recommend it to do all that is claimed for it, if directions are followed.



Yours respectfully,
H. B. PRESCOTT, Engineer.

Four months ago this belt was as tight as a fiddle string, under about 1,000 lbs. initial tension, and yet was slipping.

There is no slip now, for it runs slack. **Cling-Surface** did it.

Many of the large hotels throughout the country are now replacing unsatisfactory batteries with the *Partz Acid Gravity Battery.*

## PARTZ SULPHO-CHROMIC SALT

FOR USE IN

PARTZ ACID GRAVITY BATTERIES

AND FOR MAKING

ELECTROPOION FLUID.

*ECONOMY—SAFETY—EFFICIENCY.*

Sulpho-Chromic Salt, when dissolved in water, makes a standard electropoion fluid without the necessity of handling liquid acids, having practically the same amount of stored energy as an equal quantity of fluid made in the ordinary ways, giving with a zinc-carbon element an E. M. F. of 1.9 to 2 volts and an ampere-hour capacity of about the same.

We especially call the attention of battery users to this substance as affording the best, cheapest, and most convenient method of making electropoion fluid for medical batteries, Grenet cells, Bunsen batteries for lecture tables, experimental work, etc., and motor batteries.

Sulpho-Chromic Salt is put up in air-tight jars, with screw-lid, each jar containing two pounds. As the salt is hygroscopic, it must be guarded against moisture.

PRICE PER JAR 2 LBS., $0.75.

Digitized by Google

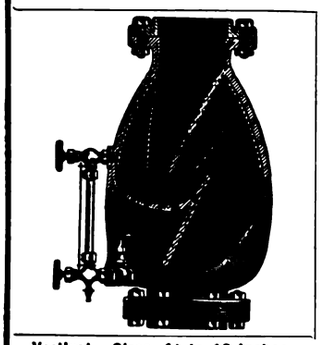
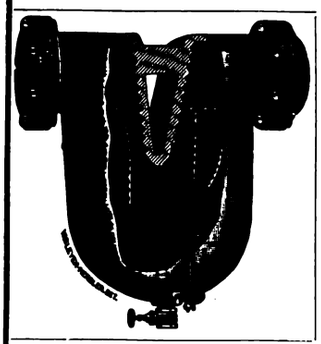
Because our COCHRANE HEATERS & PURIFIERS take out a lot of impurities, we make the cleaning doors of large size and easy to open — make the trays easily removable — provide all facilities for charging with and removing the filtering material, etc., etc.

It is not only cleaning doors and large capacity which commend these "COCHRANES" to the steam user —all the other points have received the most careful consideration. May we tell you about them?



AND THERE'S ROOM INSIDE!

We believe in making our COCHRANE Heaters of generous proportions, because the slow travel of water through a Heater is an essential in obtaining *real* purification.



**HARRISON SAFETY BOILER WORKS, Mfrs.,**

3124 N. 17th Street, Philadelphia, Pa.

# Judge and Jury.

Vertical.—Sizes, 1½ to 10 inches.

Horizontal.—Sizes, 1½ to 12 inches.

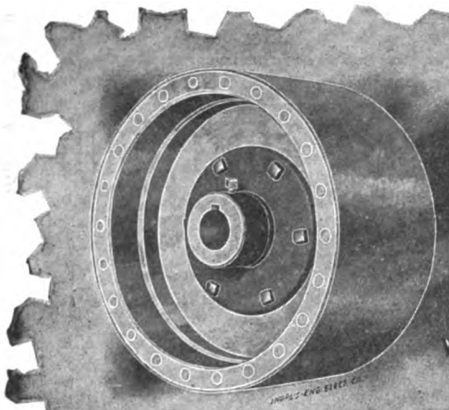
Buyers of Austin Separators may be both Judge and Jury.

We put them in on 30 days trial and have never been asked to take them out in a single instance in the thousands of cases where we have sold on this basis.

There need be no question of selection if you want a steam or oil separator.

## The Austin Separator

guarantee is broad and liberal and means entire satisfaction or no sale.



The practical advantages of a Separator on Steam Plants in any service are known to every up-to-date engineer, and yet there are thousands of manufacturers who are throwing away good money every day by not using them.

Our catalogue may convince you that you need one, and that one the Austin Separator.

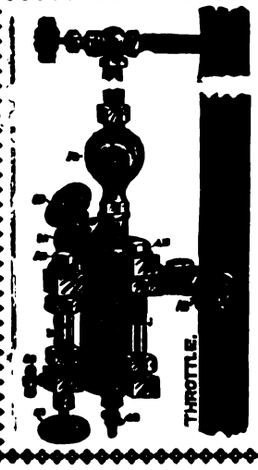
# THE AMERICAN STOKER CO., WASHINGTON LIFE BUILDING, BROADWAY & LIBERTY ST., NEW YORK.

Digitized by Google



# One of the Oldest and Most Common Remedies for Boiler Scale is Kerosene.

Although the use of kerosene is a very crude practice it is in the right direction, as the wide-spread popularity of the custom indicates. Kerosene contains as one of its ingredients a heavy oil which forms a film on the boiler surfaces, preventing the adhesion of scale thereto. It also contains several deleterious ingredients which cause foaming and other troubles. The one valuable ingredient is separated from all harmful by-products and is on the market under the name of Pittsburgh Boiler Scale Resolvent. With this you can safely lubricate your boilers and prevent the deposition of scale or the harmful action on the iron of acid waters. Made by the

# The Detroit Lubricators in Good Company.

Fully nine-tenths of the prominent American engine builders use **The Detroit Lubricators** on their engines. They will not equip an expensive engine with an inferior or mediocre lubricator, as their experience has taught that the risk is too great. This preference by those best qualified to judge of their merits is the best recommendation that could be given to our goods. Another good recommendation is the constantly increasing demand we are having for them. We are now sending out over **5,500 Detroit Lubricators** per month, and have to increase our facilities to keep up with the demand.

**Our Catalogue showing our different Lubricators, Glass and Brass Oilers, Oil Pumps, etc., will be sent on application.**

**A REALIZATION from ACTUAL LIFE.**

## Electric Light Plants.
## Street Railway Plants.
## Manufacturing Plants.

THE fuel bill is the great item of expense at Power Stations; 15 per cent. is utilized, 85 per cent. becomes a by-product. Do the Gas Companies and the Oil Refiners squander their by-products? If they did how long would they keep out of the receiver's hands? Every 100 H. P. of exhaust steam will heat 1,000,000 cubic feet of space in stores, churches, dwellings, offices, etc., and will sell for $2,500 to $3,500. The income thus secured will pay fuel bills at the Power Station for the entire year. This is not a guess, for it is being done by many concerns who are using the Holly System.

Mr. Manager, are you doing your duty when you sit idly by and see your stockholders robbed? It is their property and you are seeing it dissipated. Learn a lesson in true economy by sending for our catalogue.

# Murphy Automatic Smokeless Furnace

THE ONLY FULLY AUTOMATIC FURNACE

## SUPERIOR RESULTS ON ALL POINTS

## SMOKE PREVENTION AND PROFIT.

### THE BEST SMOKE PREVENTION AND THE BEST ECONOMY GO TOGETHER

A smoking chimney, in connection with a large, fine building or manufactory, is an offence to the public and a constant useless waste to those who pay the fuel bills, and, in the light of known facts of to-day, it is a reflection on those responsible.

Any boiler plant equipped with an "up-to-date" furnace will burn the "steam" grade of soft coal without smoke and with decided extra profit to the owner, or whoever pays the fuel bill.

There are scores of plants in various localities where

PROFITABLE SMOKE PREVENTION

has been and is being daily demonstrated by use of the

MURPHY AUTOMATIC SMOKELESS FURNACE.

No matter what form of the common or of the so-called "improved" or "patent" furnace you now have, the Murphy will give you increased economy, better **smoke prevention** and better service in general.

Do you doubt it? Let us have opportunity and we will prove it in your boiler room.

*BRANCH OFFICES:*
*Chicago, Ill., Bedford Building.*
*Cincinnati, O., Neave Bldg.*
*Pittsburg, Pa., Lewis Block.*
*Philadelphia, Pa., Stevens Girard Building.*

*MURPHY IRON WORKS*
*DETROIT, MICH.*

P. S.—We wish to call the attention of those who are using our older forms of construction to the fact of recent improvements, which can be applied to all our furnaces, making the furnace more completely self-cleaning and more durable and satisfactory than ever.

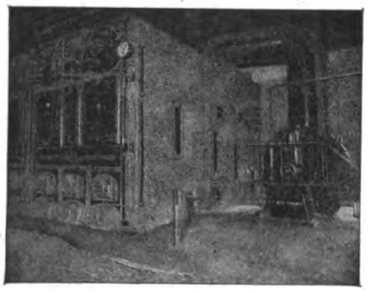
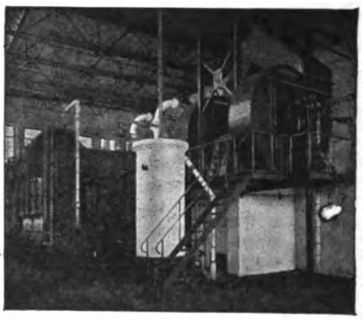
Good Draft
Is essential to success with any boiler plant.

Better Draft
Can be produced by a fan at less first cost and running expense than by a chimney.



Best Draft
is, therefore,
Mechanical Draft
by which these results can be secured.



This is the size of the chimney and This is the size of the fan required for the same boiler capacity.
COMMENT IS UNNECESSARY.

# Mechanical Draft

What it is ...and What it Does.

It is draft mechanically produced by means of a fan, and may be introduced either as forced draft, by which the air under pressure is delivered to the ash pits, or as induced draft, arranged to draw the gases through the fan and to maintain a partial vacuum within the furnace. The method to be adopted must of necessity depend upon the existing conditions.

It does what an ordinary chimney is incapable of doing. Its cost is from 20 to 40 per cent. of that of a chimney; its intensity permits of the burning of finely divided or low grade fuel; it makes possible the utilization of the heat of the flue gases which a chimney wastes in producing draft; it is independent of the weather; is automatically regulated to maintain constant steam pressure, prevents smoke, increases the capacity of an existing plant, and serves as an auxiliary to a chimney already overburdened; it saves space and is portable.

Send for our Treatise on this subject. Plans and estimates cheerfully furnished.

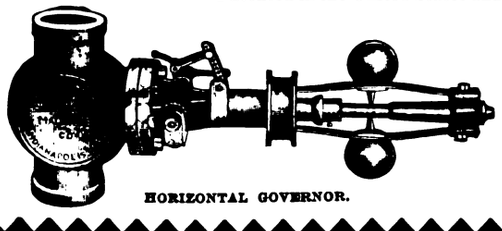
# THE MONARCH GOVERNOR

**THE ONLY GOVERNOR ON EARTH THAT WILL ACCURATELY REGULATE ANY TYPE OF ENGINE.**

**Built with automatic safety stop, speed adjuster and valve lever, and possesses all the elements of a first-class Governor.**



The most sensitive and the quickest acting Governor made in the world.
Neat in design, first-class in workmanship and material.
Accurately fitted to gauges and all parts interchangeable.
The valve throw of this governor being adjustable independently of the radial throw of the Governor Balls or the normal speed of the engine, the closest possible regulation can be obtained for any style of engine or motor to which a throttling Governor can be used.

CLASS A.—SHOWING AUTOMATIC STOP.

**Adapted to all varieties of Steam Engines and fitted with special valve chambers to suit any style of Gas Engine of the throttling type.**

Patented in the United States and Canada and all the principal countries of the world.

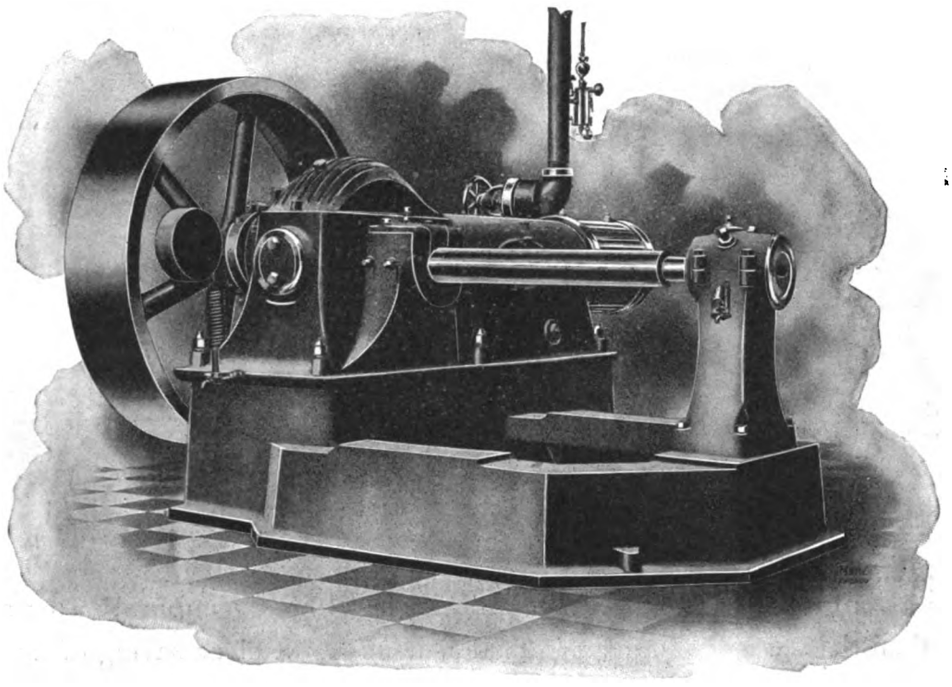
# ....OUR NEW....



## Internal Oiling... Automatic Steam Engine

is unequalled in design and possesses more points of real excellence than any in the field at the present time. It is a high-class engine in every sense of the word, and contains a number of points of superiority, of which we mention only the most important:

***A STEAM TIGHT VALVE.***—Our valve automatically and continuously takes up its own wear and is absolutely steam tight.

***SIMPLEST GOVERNOR.***—Our governor consists of but one moving part, while the regulation is unexcelled.

***TAKING UP WEAR.***—The means of adjustments on connecting rod, main bearings, valve rod and eccentric rod are superior to any.

***SUPERIORITY AND ECONOMY OF OILING.***—The oiling is automatic and positive, commencing when engine starts and stopping when it is shut down, and requires no attention. There is uniform and copious lubrication of the various wearing parts, the passages being large and direct.

There are no **oil cups or tubes** of any kind to clog up or become inoperative.

The oil is not **exposed** to the open air or to contamination with foreign substances, as the oiling is entirely internal.

There is no saponification or aeration, and the oil is kept cool and clean.

It is by far the most economical and reliable oiling system, and the engine being entirely closed, there is no throwing of oil on surrounding objects.

Send for a pamphlet describing the engine if you are interested.

## BALL ENGINE COMPANY, Erie, Pa.
